Reactions and Combinations.—1. S_2Cl_2 sinks in *water*, and then decomposes, giving HClAq, SO_2Aq, and S, with a little H_2SAq, $H_2S_2O_3Aq$, and some of the thionic acids.—2. *Hydrogen sulphide* produces HCl and S; *hydrogen iodide* reacts at the ordinary temperature to form HCl, I, S_2I_2, and then H_2S (Hautefeuille, *Bl.* [2] 7, 198).—3. By passing S_2Cl_2 vapour, mixed with *air* or *oxygen*, through a red-hot tube, SO_2, SO_3, and Cl are formed (Donny a. Mareska, *C. R.* 20, 817; Spring a. Lecrenier, *Bl.* [2] 45, 867).—4. Heating with *phosphorus* produces PCl_3, $PSCl_3$, and S if a little P is used; or PCl_3, P sulphides, and red P if much P is used (Wöhler a. Hiller, *A.* 93, 274; Chevrier, *C. R.* 63, 1003).—5. Heated with many *metals*, S_2Cl_2 gives metallic chlorides and S; the more volatile the metallic chloride the more readily does the reaction occur (*v.* Chevrier, *C. R.* 64, 302).—6. S_2Cl_2 combines with *chlorine*, forming SCl_2 and SCl_4 (*q.v.*, *infra*). Br and I are absorbed by S_2Cl_2; according to Evans a. Ramsay (*C. J.* 45, 65) no compound is formed with Br.—7. With *oxides of arsenic and antimony* S_2Cl_2 forms $AsCl_3$ and $SbCl_3$, giving off SO_2 and separating S; *selenion dioxide* produces Se_2Cl_2 and SO_2; *oxides of phosphorus, boron, and silicon* do not react (Prinz, *A.* 223, 355).—8. S_2Cl_2 absorbs *sulphur trioxide*, below 0°, forming a brownish-yellow liquid, from which excess of SO_3 crystallises out; a little above 6° SO_2 is given off, rapidly at 10°; $S_2O_5Cl_2$ is formed on distillation (Rose, *P.* 44, 291).—9. By passing vapour of S_2Cl_2 along with the vapours from *sulphonic acid* through a hot tube, SO_2, H_2S, S, HCl, and Cl are produced (Brault a. Poggiale, *J. Ph.* 21, 140).—10. Heating S_2Cl_2 with *sulphates* generally produces SO_2Cl_2, chlorides, S, and SO_2; heated with *sulphuryl chloride* to 250°, S_2OCl_4 is formed (*v.* Schneider, *J. pr.* 104, 83; [2] 32, 18; Demarçay, *C. R.* 92, 726).—11. S_2Cl_2 combines with *ammonia gas* to form $S_2Cl_2.4NH_3$, stable in air, sol. alcohol, decomposed by water giving NH_4ClAq, $(NH_4)_2S_2O_3Aq$, and S (Brault a. Poggiale, *J. Ph.* 21, 140).—12. Reacts with *organic compounds containing oxygen*, generally forming Cl compounds and small quantities of S compounds, and also HCl, SO_2, and S.—13. Combines with *unsaturated hydrocarbons*; *e.g.* with C_2H_4 forms $C_2H_4S_2Cl_2$.

SULPHUR DICHLORIDE SCl_2. Mol. w. (in solution in benzene or acetic acid) 102·72. S.G. 1·6482 at 15·4° (Costa, *G.* 20, 367). $\mu_{H_\alpha} = 1{\cdot}5716$ (Costa, *l.c.*). No constant b.p. (*v. infra*). This compound was prepared by *H.* Rose in 1831 (*P.* 21, 431; 27, 117); the experiments of Dumas (*A. Ch.* [2] 49, 204) and Marchand (*J. pr.* 22 507) led to its recognition as a definite compound (*v.* also Carius, *A.* 106, 291); Hübner a. Guerout (*Z.* 1870. 455) isolated the compound satisfactorily, and their results were confirmed by Thorpe a. Dalzell, in 1871 (*C. N.* 24, 159). Costa, in 1890 (*G.* 20, 367), determined the mol. w. of the compound in solution.

Preparation.—Dry Cl is led into S_2Cl_2, surrounded by a freezing mixture, until the liquid becomes deep red; excess of Cl is removed by a stream of dry CO_2. The temperature must not rise above 6°; the vessel containing the S_2Cl_2 should be kept filled with Cl continually, and should not be exposed to direct sunlight (H. a. G., *l.c.*; C., *l.c.*; T. a. D., *l.c.*; also Soubeiran *A. Ch.* [2] 67, 64; Michaelis, *A.* 170, 1).

Properties. — A thin, dark, brownish-red, liquid, with smell and taste like S_2Cl_2; does not solidify at $-30°$; gives off Cl when exposed to sunlight, and should, therefore, be kept in a sealed tube in the dark. Easily decomposed by heat to S_2Cl_2 and Cl; Michaelis (*B.* 6, 995) gives a table showing amount of dissociation from 20° to 130°; the temperature whereat 50 p.c. of the SCl_2 is dissociated is c. 86°. SCl_2 reddens dry litmus paper. The depression of the freezing-point of benzene or glacial acetic acid by solution therein of SCl_2, shows that the mol. w. agrees with the formula SCl_2 (Costa, *G.* 20, 367).

Reactions and Combinations.—1. *Heat*, or direct *sunlight*, causes dissociation to S_2Cl_2 and Cl (*v. supra*, *Properties*).—2. *Water* produces HClAq and $H_2S_2O_3$Aq.—3. Oxidised violently by *nitric acid* to HClAq and H_2SO_4Aq.—4. *Ammonia solution* produces NH_4ClAq, N, and S; *ammonia gas* combines to form $SCl_2.2NH_3$ and $SCl_2.4NH_3$, soluble, unchanged, in absolute alcohol and ether (Soubeiran, *A. Ch.* [2] 67, 74).—5. *Thionyl chloride* ($SOCl_2$), when heated with SCl_2, forms S_2OCl_4 (Ogier, *Bl.* [2] 37, 293).—6. *Alkali sulphites* produce chlorides and trithionates (Spring a. Lecrenier, *Bl.* [2] 45, 867).—7. Some *metals*, *e.g.* Cu, Fe, K, react with SCl_2, with production of heat and light, and formation of chlorides and sulphides.—8. Combines with *arsenious chloride*, forming $AsCl_3.SCl_2$ according to H. Rose (*P.* 27. 107).—9. SCl_2 reacts with *oxygenised carbon compounds* similarly to, but more readily than, S_2Cl_2; it combines with several *unsaturated hydrocarbons* (*v.* Heintz, *A.* 100, 370; Guthrie, *C. J.* 12, 109).

Sulphur tetrachloride SCl_4. This compound exists only at temperatures under $-20°$. The molecular weight is probably 173·46 (SCl_4).

Preparation.—S_2Cl_2 is cooled to below $-20°$ (c. $-22°$) and a slow stream of dry Cl is passed in until absorption of Cl ceases. Michaelis a. Schifferdecker (*B.* 6, 993) found that 67·5 g. S_2Cl_2, kept at $-20°$ to $-22°$, absorbed 106 g. Cl in 10 hours, that absorption of Cl then ceased, and that the liquid had the composition SCl_4.

Properties.—A mobile, yellowish-brown liquid; when removed from the freezing mixture used in the preparation, the liquid gives off Cl, and boils with an absorption of much heat. M. a. S. give the following data showing the dissociation of SCl_4 to SCl_2 and Cl:—

Temp.	P.c. SCl_4	P.c. SCl_2
− 22°	100·0	0·0
− 15	41·95	58·05
− 10	27·62	72·38
− 7	21·97	78·03
− 2	11·93	88·07
+0·7	8·87	91·13
+6·2	2·43	97·57

Reactions.—1. *Water* causes rapid decomposition to HClAq and SO_2Aq, with more or less S according to the mass and temperature of the water.—2. With *sulphur trioxide*, in the ratio $SCl_4:SO_3$ the products are $SOCl_2$ and $S_2O_5Cl_2$, in the ratio $SCl_4:2SO_3$ the products are $SOCl_2$, SO_2, and Cl (M. a. S., *l.c.*; also *B.* 5, 924). *Sulphur dioxide* does not react.—3. *Chlorosulphonic acid* reacts at a low temperature to form $S_2O_3Cl_4$ and HCl (M. a. S., *B.* 6, 996).—4. With some *hydroxylic organic compounds*, *e.g.* $C_2H_5.OH$ and $C_6H_5.CO.OH$, OH is replaced by Cl and $SOCl_2$ is formed.

Combinations.—1. Compounds of SCl_4 with several *metallic chlorides* are produced by warming the chlorides with S_2Cl_2 and passing in Cl; the compounds $2AlCl_3.SCl_4$, $AuCl_3.SCl_4$, and $2TiCl_4.SCl_4$ are formed thus (Weber, *P.* 104, 421; Rose, *P.* 42, 517; Casselmann, *A.* 83, 267). The compound with $AlCl_3$ may be distilled in a closed ⋀ shaped tube; the other two compounds give off Cl when heated. The compounds $SbCl_5.3SCl_4$ and $SnCl_4.2SCl_4$ are produced by passing Cl over SnS_2 and Sb_2S_3 respectively (R., *l.c.*; C., *l.c.*).—2. With *iodine trichloride* forms $ICl_3.SCl_4$ (Weber, *P.* 128, 459; *cf.* Jaillard, *A. Ch.* [3] 59, 454, who gives the composition $SCl_2.2ICl_3$). Prepared by passing Cl into I dissolved in CS_2 till the liquid is wine-red, cooling, and drying the red-yellow, prismatic, very deliquescent, crystals, in a tube in a stream of dry Cl. Also formed by passing Cl into a mixture of 2 pts. S and 1 pt. I. Melts to a brown liquid when heated in a closed tube; heated in an open tube forms Cl, ICl, and S_2Cl_2; decomposed by water or dilute HNO_3Aq.

Sulphur, chloro-iodide of, $SCl_7I(=SCl_4.ICl_3)$; *v. supra*, Sulphur tetrachloride, *Combinations*, No. 2.

Sulphur, chloronitride of, S_2ClN; *v.* Nitrogen sulphochloride, vol. iii. p. 571.

Sulphur, cyanides of, *v.* Cyanogen, sulphides, vol. ii. p. 358.

Sulphur, fluoride of. According to Gore (*Pr.* 20, 70 [1871]) the heavy colourless gas produced by fusing AgF with S is a fluoride of S. This gas is not liquefied at 0°, at the ordinary pressure; it fumes in the air, and attacks glass; no analyses are given by G.

Sulphur, haloid compounds of. The most stable of these compounds belong to the forms S_2X_2; where X = Cl, Br, or I. The chloride S_2Cl_2, may be distilled unchanged; the bromide, S_2Br_2, is exceedingly easily decomposed if, indeed, it has been isolated; the iodide, S_2I_2, has been very slightly examined. The compounds SCl_2 and SCl_4 also exists; the former at temperatures below c. 10°, and the latter below c. $-20°$. The compound SI_6 perhaps exists; it gives up I at the ordinary temperature. The only haloid compound of S that has been gasified unchanged is S_2Cl_2.

Sulphur, hydrides of, SH_2 and (?) S_5H_2; *v.* Hydrogen sulphides, vol. ii. p. 725.

Sulphur, nitride of, SN; *v.* Nitrogen sulphide, vol. iii. p. 570.

Sulphur, iodides of. S and I probably combine when heated together, but no definite compound has been isolated by this method (*cf.* Gay-Lussac, *G. A.* 48, 372; H. Rose, *P.* 27, 115; Lamers, *J. pr.* 84, 349; Sestini, *J.* 1868. 153; Wheeler a. Lüdeking, *Fr.* 26, 602).

Sulphur mono-iodide S_2I_2. Guthrie (*C. J.* 14, 57) obtained this compound by placing 2½ parts EtI and 1 part S_2Cl_2 in a sealed tube, opening after 12 hours, evaporating EtCl by warming with the hand and removing excess of EtI by gently warming; the S_2I_2 crystallised out in lustrous crystals resembling I. (One analysis is given, but no full description of properties.)

Ogier (*C. R.* 92, 922) gives H.F. $[S^2, I^2]$ (from gases) = 10,800.

SULPHUR HEXA-IODIDE SI_6. This compound is said to be formed by slowly evaporating, at a low temperature, a solution of I with slight excess of S in CS_2. Grey-black crystals; resembling, and isomorphous with, I; I evaporates on exposure to air and eventually only S remains; alcohol, conc. KOHAq, or KIAq, also withdraws all I (G. vom Rath, *P.* 110, 116; Lamers, *J. pr.* 84, 349). It is very doubtful whether the crystals examined by vom Rath were a compound or only I retaining a little S.

By passing H_2S into a dilute solution of $KCl.ICl_3$, Lamers (*l.c.*) obtained an orange-red pp. which dried in an exsiccator to a brown amorphous mass containing S and I in the ratio S_3I_2.

By subliming SnS_2 with I, Schneider (*J.* 1860. 186) obtained a compound to which he gave the composition $SnSI_2.SI_2$.

Sulphur, iodochloride of, $SICl_7$ $(= SCl_4.ICl_3)$ *v.* SULPHUR TETRACHLORIDE, *Combinations* No. 2.

Sulphur, oxides of. Four compounds have been isolated; S_2O_3, SO_2, SO_3, and S_2O_7. S and O combine directly to form SO_2 and SO_3; S dissolves in SO_3 to form S_2O_3; S_2O_7 is formed by the action of an electric discharge on a mixture of SO_2 and O, or SO_3 and O.

SULPHUR SESQUIOXIDE S_2O_3 (*Hyposulphurous anhydride*). The production of a blue substance, on distilling fuming H_2SO_4 and S, was noticed by Buchholz in 1804 (*Gehlen's J.* 3, 7); Vogel, in 1812, obtained the blue body by bringing together S and SO_3 (*S.* 4, 121); the substance was examined by Wach (*S.* 50, 1), Berzelius (*Lehrbuch* [5th edit.] 1, 485), and Stein (*J. pr.* [2] 6, 172). Weber, in 1875, isolated the compound and found its composition to be S_2O_3 (*P.* 156, 531).

S_2O_3 is prepared by adding well-dried flowers of sulphur, little by little, to SO_3 quite free from H_2SO_4, more S being added when the previous quantity has all combined. The process is conveniently conducted in a test tube, covered with a small porcelain crucible to exclude moisture, and plunged into water cooled to c. 12°; the S disappears in the SO_3 and blue drops are formed; the tube should be tilted so that the blue drops come into contact with the sides of the tube where they form a thin crust (if the drops solidify as they float in the SO_3, the solid S_2O_3 retains SO_3, from which it cannot be freed). When c. 1 g. S has been added, excess of SO_3 (which should be colourless) is poured off, the last traces being removed by gently and carefully warming not above 35°; the solid S_2O_3 is scraped out of the tube by a glass rod.

S_2O_3 is a blue-green solid, consisting of a mass of microscopic crystals. Insoluble pure SO_3; if a little H_2SO_4 is present the S_2O_3 dissolves to a deep-blue liquid. Melts with decomposition; decomposes slowly in dry air, quickly on heating, to SO_2 and S; deliquesces in moist air to a brown liquid from which S soon separates; reacts violently with water, giving H_2SO_4Aq, SO_2Aq, $H_2S_2O_3Aq$, polythionic acids, and S; decomposed also by alcohol and ether, with separation of S, also by ordinary H_2SO_4.

S_2O_3 may be regarded as the anhydride of $H_2S_2O_4$; although the acid has not been obtained from the oxide, nor the oxide from the acid.

For the compounds $SSeO_3$ and $STeO_3$ *v.* *Selenion thio-oxide* (p. 441) and *Tellurium thio-oxide* (under TELLURIUM OXIDES).

SULPHUR DIOXIDE SO_2. (*Sulphurous oxide. Sulphurous anhydride. Thionyl oxide.*) Mol. w. 63·9. Melts at c. −76° (Faraday, *T.* 1845. 155); c. −80° (Mitchell, *A.* 37, 356). Boils at c. −10° (Bunsen, *P.* 46, 97; Andréeff, *J.* 1859; Pictet, *C. C.* 1877. 81). S.G. (liquid) 1·4911 at −20·5°, 1·4384 at −2·08°, 1·4252 at +2·8°, 1·3769 at 20°, 1·3258 at 38·65° (Andréeff, *A. Ch.* [3] 56, 317); 1·4338 at 0°, 1·2872 at 52°, 1·1845 at 82·4°, 1·1041 at 102·4°, ·956 at 130·3°, ·7317 at 151·75°, ·52 at 156° (Cailletet a. Mathias, *C. R.* 104, 1563). S.G. (gas at 0° and 760 mm.) 2·2639 (Leduc, *C. R.* 117, 219). V.D. 32·23 (Gay-Lussac, Berzelius, Buff; Biltz, *B.* 21, 2769). S.H. (equal wt. water = 1) ·1544; (equal volume air = 1) ·3414 (Regnault, *J.* 1863. 84). Ratio of S.H. constant pressure to S.H. constant volume = 1·2562 (Müller, *W.* 18, 94). C.E. ·00423 for 1° between 0° and 10°, ·004005 10° to 20°, ·003846 at 50°, ·003757 at 100°, ·003718 at 150°, ·003695 at 200°, ·003685 at 250° (Amagat, *C. R.* 73, 183; *cf.* *C. R.* 68, 1170). Leduc (*C. R.* 117, 219) gives C.E. between 0° and 20° as ·00396. For C.E. of liquid SO_2 *v.* Drion (*A. Ch.* [3] 56, 5) and Andréeff (*A.* 110, 1). The ratio $\frac{PV}{P_1V_1} > 1$; Amagat (*l.c.*) gives these values,

1·0185 at 15°, 1·0110 at 50°, 1·0054 at 100°, 1·0032 at 150°, 1·0021 at 200°, 1·0016 at 250°. H.F. $[S,O^2] = 71,070$ from solid rhombic S; 71,720 from solid monoclinic S (*Th.* 2, 247). Heat of liquefaction of gaseous SO_2 = 5644 (Favre, *A. Ch.* [5] 1, 209). Critical temperature = 156° (Cailletet a. Mathias, *C. R.* 104, 1563); 155·4° (Sajotscheffski, *P. B.* 1879. 741); 157°–161° (Ladenburg, *B.* 11, 821). Heat of vaporisation of liquid SO_2, at 0° = 91·2, at 60° = 69 (C. a. M., *l.c.*; *cf.* Chappuis, *C. R.* 104, 897). Regnault (*C. R.* 50, 1063) gives vapour pressures as follows:

Temp.	Vap. pressure	Temp.	Vap. pressure
−25°	373·79 mm. Hg	30°	3131·80 mm. Hg
−20	479·46 "	40	4670·23 "
−10	762·49 "	50	6220·01 "
0	1165·06 "	60	8123·80 "
+10	1719·55 "	65	9221·40 "
20	2462·05 "		

Vapour-pressure at critical temp. = 78·9 atmos. (Sajotscheffski, *P. B.* 1879. 741). S. in water between 0° and 20° (gaseous SO_2) = $79·789 - 2·6077t + ·029349t^2$; 1 vol. of the saturated SO_2Aq contains $68·861 - 1·87025t + ·01225t^2$ vols. SO_2; S. (water) between 21° and 40° = $75·182 - 2·1716t + ·01903t^2$; 1 vol. of the saturated SO_2Aq contains $60·952 - 1·38898t + ·00726t^2$ vols. SO_2 (Bunsen a. Schönfeldt, *A.* 95, 2). S. in alcohol, at 760 mm. = $328·62 - 16·95t + ·3119t^2$; S.G. of solution = $1·11937 - ·014091t + ·000257t^2$ (Carius, *A.* 94, 148). Sims (*C. J.* 14, 1) gives the table on the next page, which presents both the weight of SO_2 in grams and the volume of gaseous SO_2 in c.c. dissolved by unit weight of water at the normal pressure and different temperatures:—

Temp.	Grams SO_2	c.c. SO_2
	absorbed by 1 g. water at 760 mm.	
8°	·168	58·7
12	·142	49·9
16	·121	42·2
20	·104	36·4
24	·092	32·3
28	·083	28·9
32	·073	25·7
36	·065	22·8
40	·058	20·4
44	·053	18·4
48	·047	16·4
50	·045	15·6

The quantity of SO_2 dissolved by a given weight of water varies with pressure, and only at c. 40° and upwards is the quantity proportional to the partial pressure of the gas (*v.* Sims, *C. J.* 14, 1). For S.G. and composition from ·5 to 10 p.c. of SO_2Aq *v.* Anthon (*C. C.* 1860. 744); also Giles a. Schearer (*S. C. I.* 4, 303). $[SO^2,Aq]=7,700$ (gaseous SO_2) (*Th.* 2, 249); 1500 (liquid SO_2) (Berthelot, *C. R.* 96, 142, 208; Chappuis, *A. Ch.* [2] 19, 21). H_2SO_4Aq absorbs the following quantities of gaseous SO_2 (Kolb, *D. P. J.* 209, 270; *cf.* Dunn, *C. N.* 43, 121; 45, 270):—

S.G. H_2SO_4Aq	Kilos. SO_2 per kilo. acid	Litres SO_2 per litre acid
1·841	·009	5·8
1·839	·014	8·9
1·540	·021	11·2
1·407	·032	15·9
1·227	·068	29·7

SO_2 is absorbed by charcoal; 1 c.c. charcoal = 1·57 g. was found by Favre (*A. Ch.* [5] 1, 209) to absorb 165 c.c. SO_2. Camphor absorbs c. 308 times its vol., glacial acetic acid c. 318 times, SO_2Cl_2 c. 187 times, its volume of SO_2 (Schulze, *J. pr.* [2] 24, 168; Bineau, *A. Ch.* [3] 34, 326). $\mu_{Na}=1·35$ at 15° (Bleekrode, *Pr.* 37, 359). For surface tension of liquid SO_2 *v.* Clark (*C. N.* 38, 294; 40, 8). For absorption-spectrum *v.* Liveing a. Dewar (*C. N.* 47, 121).

Occurrence.—In volcanic gases, and in river and spring water near volcanoes (*v.* Ricciardi, *G.* 18, 38).

Formation.—1. By burning S in O. Baker (*Pr.* 45, 1; *C. J.* 47, 349) found that the combustion of S in O is retarded the drier the O is; using very carefully dried O there was no flame. According to Hempel (*B.* 23, 1456) c. 2 p.c. of the gas formed when S is burnt in O at the ordinary pressure is SO_3, 98 p.c. being SO_2; at a pressure of 40°–50° atmos. c. half the S is burnt to SO_2 and half to SO_3; at higher pressures c. 70 atmos. the proportion of SO_2 increases.—2. By heating S with oxide of Pb, Mn, Hg, Zn, &c.—3. By heating various sulphates with S, also SO_3 with S, or conc. H_2SO_4 with C, Cu, Hg, or S; by heating Na_2SO_4 with charcoal and SiO_2.—4. By the decomposition, by acids, of alkali thiosulphate or polythionate solutions.—5. By burning H_2S, CS_2, and various organic compounds containing S.—6. By decomposing conc. H_2SO_4 by heat.—7. By the action of electric sparks on a mixture of sulphur with CO_2, NO, or N_2O (Chevrier, *C. R.* 69, 136).

Preparation.—1. Pure H_2SO_4, mixed with half to two-fifths its volume of water, is heated with pure Cu; the SO_2 that comes off is passed through water in a large flask, and then through a couple of bottles filled with pumice, broken into small pieces and moistened; the pumice should be twice moistened with pure H_2SO_4 and heated to redness before being used, to remove chlorides and fluorides (Stas, *Chem. Proport.* 115). The SO_2 may be dried by passing it through pure conc. H_2SO_4, and then over $CaCl_2$.—2. A mixture of 3 parts pure CuO and 1 part S in powder is heated in a tube of hard glass; the anterior part of the tube contains CuO only, to oxidise S that may sublime (Marchand, *P.* 42, 144).—3. Neumann (*B.* 20, 1584) obtains a regular stream of approximately pure SO_2 by placing a mixture of three parts $CaSO_3$ and 1 part $CaSO_4$, made into small cubes, in a Kipp's apparatus, and decomposing by ordinary oil of vitriol. The acid should be allowed to come into contact with sufficient cubes, and no more, to give the stream of gas that is required. Using c. 500 g. of the cubes, N. obtained a constant stream of SO_2 for 30 hours. The cubes are made by mixing the $CaSO_3$ and $CaSO_4$, moistening with water so that a semi-solid mass is obtained that can be worked with the fingers with some difficulty, pressing this in an iron mortar, hammering it into an iron frame c. 10–12 mm. in height, covering with oilcloth and pressing strongly, cutting into cubes while still in the frame, removing and drying at c. 20° (*v.* Winkler, *B.* 20, 184).

Properties.—A colourless gas, at ordinary temperatures and pressures, with the strong penetrating, choking odour of burning S; causes coughing and blood-spitting if inhaled in any quantity. Incombustible in air, and extinguishes flame; when mixed with O and passed over heated spongy Pt it is oxidised to SO_3. Dry SO_2 is said not to redden litmus paper (Wilson, *C. J.* 1, 332). Bleaches many vegetable colours; the colours are generally restored by alkalis. Bad conductor of electricity (*v.* Bleekrode, *P. M.* [5] 5, 375, 439). Is not decomposed by passing through a red-hot tube. Condensed at c. −10° under the ordinary pressure—by passing the dry gas into a tube surrounded by a mixture of snow and salt; may also be condensed at the ordinary temperature by evolving the gas (by warming charcoal saturated with SO_2, or a mixture of 1 part S and 5 parts SO_3) in one limb of a closed tube, the other limb being placed in cold water. Convenient apparatus for liquefying SO_2 is described by Wöhler (*A.* 137, 371) and Hofmann (*B.* 2, 262).

Liquid SO_2 is a colourless, mobile liquid. Exposed to air it evaporates very rapidly, with disappearance of much heat; an air thermometer placed in liquid SO_2 at 10°, in an open vessel, falls to −57°. Liquid SO_2 dissolves P, S, I, Br, and many gums. It is miscible in all proportions with liquid SO_3; partially miscible with CS_2, Et_2O, $CHCl_3$, and C_6H_6 on warming; but immiscible with conc. H_2SO_4 (Sestini, *Bl.* [2] 10, 226). Liquid SO_2 is a non-conductor of electricity (Magnus, *P.* 104, 553).

By evaporating liquid SO_2 rapidly in an air-pump, part of it solidifies to a white, woolly mass; the liquid may also be solidified by placing it in a mixture of solid CO_2 and ether.

Reactions and Combinations.—1. SO_2 is not decomposed by passing through a red-hot tube. But by *heating* to c. 1200° it is changed to SO_3 and S ($3SO_2 = 2SO_3 + S$); the action stops when the SO_3 attains a certain vapour pressure, but if the SO_3 is removed (by conc. H_2SO_4) the whole of the SO_2 is decomposed (Deville, *C. R.* 60, 317). *Induction sparks* effect the decomposition of SO_2 to SO_3 and S (*v.* Buff a. Hofmann, *A.* 113, 129); *light* acts similarly (Morren, *C. R.* 69, 397).—2. H_2O and S are produced by passing SO_2 mixed with *hydrogen* through a red-hot tube.—3. *Chlorine* combines with SO_2, in sunlight, to form SO_2Cl_2 (*v.* Sulphuryl chloride). SO_2Cl_2 is also formed by passing SO_2 and Cl into glacial acetic acid, even in the dark; also by passing SO_2 over charcoal saturated with Cl (Melsens, *C. R.* 76, 92).—4. *Ozone* produces SO_3; the same compound is formed by passing SO_2 mixed with *oxygen* over heated spongy Pt, or by burning SO_2 in O under a pressure of several atmos. (*v. supra; Formation,* No. 1). According to Berthelot (*A. Ch.* [5] 12, 463), S_2O_7 is formed by the action of the *silent discharge* on SO_2 mixed with *oxygen*. The compound $S_2O_9N_2$ is said to be formed by passing *electric sparks* through a mixture of SO_2 and *air*. This compound is probably $S_2O_5(NO_2)_2$ (*v.* Nitrosulphonic anhydride, p. 601).—5. Passed over red-hot *carbon* the products are CO, CO_2, and S; COS and CS_2 are also sometimes formed, probably by secondary reactions (Scheurer-Kestner, *C. R.* 114, 296; *cf.* Berthelot, *Bl.* [2] 40, 362; Eilsart, *J.* 1885. 457).—6. *Potassium* burns when heated in SO_2, giving K_2SO_4, $K_2S_2O_3$, and polysulphides.—7. Many other *metals*, especially when in fine powder, burn in SO_2; Sb and Sn form oxides and sulphides; Fe, sulphide and sulphate; Pd and Pt, sulphides and SO_3; Au, S and SO_3; Mg, sulphate, sulphite, and sulphide; Al, Co, Ni, and Zn also burn; Bi and Hg do not react (Schiff, *A.* 67, 94; 117, 92; Uhl, *B.* 23, 2151).—8. *Water* dissolves SO_2, forming H_2SO_3Aq (*v.* Sulphurous acid, p. 614). 9. Several *metallic peroxides* combine readily with SO_2, forming sulphates; *e.g.* $PbO_2 + SO_2 = PbSO_4$; in this reaction much heat is produced.—10. *Nitrogen dioxide* is said to react with liquid SO_2 to form *nitrosulphonic anhydride* $S_2O_5(NO_2)_2$ (*v.* p. 601). With *nitric oxide* or *dioxide, in presence of water, nitrosulphonic acid* $NO_2(SO_2.OH)$ (*q.v.*, p. 601) is formed. *Nitric oxide in presence of alkali* produces salts of $SO_2.OH(NO)_2.H$ (*v.* Nitrososulphates, p. 581).—11. *Selenion dioxide* does not react with SO_2 (Schulze, *J. pr.* [2] 32, 390).—12. Dry *hydrogen sulphide* does not react; moist H_2S, at the ordinary temperature, produces $H_2S_5O_6$, S, and H_2O (Cluzel a. Schmid, *Chem. Zeitung,* 11, 50); there is said to be no reaction in presence of water above 400° (Mulder, *J.* 1858. 84).—13. *Phosphoretted hydrogen* reacts at the ordinary temperature to form H_2O and P_2S_5 (C. a. S., *l.c.*).—14. *Ammonia* combines with SO_2 probably producing $SO_2.NH_3$ ($= SO.OH.NH_2$) and $SO_2.2NH_3$ ($= SO.ONH_4.NH_2$) (*v.* Thionamic acid).—15. *Hydrochloric* or *hydriodic acid* produces H_2O, S, and Cl or I.—16. Many *oxy-salts, e.g.* nitrates and chlorates, react with SO_2, when heated, to form sulphates and N oxides; at higher temperatures SO_3 is sometimes produced (*v.* Hodgkinson a. Young, *C. N.* 66, 199).—17. *Alkali nitrites* yield salts of *nitrilosulphonic acid* $N(SO_2.OH)_3$ (*q.v.*, p. 601), and salts of *oxy-imidosulphonic acid* $N(OH)(SO_2.OH)_2$ (*q.v.*, p. 602).—18. Combines with *aluminium chloride* at 50°–60°, forming $AlCl_3.SO_2$, which gives off SO_2 at a higher temperature (Adrianoffski, *B.* 12, 688).—19. *Phosphorus pentachloride* produces $POCl_3$ and $SOCl_2$ (Kremers, *A.* 70, 297; Schiff, *A.* 102, 111).

Sulphur trioxide SO_3. (*Sulphuric oxide. Sulphuric anhydride.*) Mol. w. 79·86. Melts at 14·8° (Weber, *B.* 19, 3189; Rebs, *A.* 246, 356). Some other observers have given m.p. as high as 29·5° (*v.* Buff, *A. Suppl.* 4, 129; Bussy, *A. Ch.* [2] 26, 411; Fischer, *P.* 16, 119; Marignac, *A.* 88, 230). Boils at 46·2° (Weber, *l.c.*; *v.* also Buff, *l.c.*; Fischer, *l.c.*; Schultz-Sellack, *P.* 139, 480). S.G. 1·94 at 16° (Weber, *l.c.*); 1·97 at 20° (Bussy, *l.c.*); 1·9086 at 25° (Buff, *l.c.*). V.D. 39·78 (Schultz-Sellack, *P.* 139, 480; Perman, *Pr.* 48, 45). H.F. $[S,O^3] = 103,240$ (liquid SO_3 from solid S; *Th.* 2, 254); $[SO^2, O] = 32,160$ (liquid SO_3 from gaseous SO_2; *Th., l.c.*); $[SO^3, Aq] = 39,170$ (liquid SO_3; *Th., l.c.*). For heat of vaporisation *v.* Berthelot (*C. R.* 90, 1510). Schultz-Sellack gives vapour-pressure at 20° as 152 mm. Hg (*P.* 139, 480).

Formation.—1. By the interaction of ozone and SO_2. Also by the action of an induction current on a mixture of SO_2 and O_2 (Buff a. Hofmann, *A.* 113, 129; Deville, *Bl.* [2] 3, 366); Berthelot (*C. R.* 86, 20) says that the product is S_2O_7.—2. By burning S in O under a pressure of several atmos. (*v.* Sulphur dioxide, *Formation* No. 1). Also by heating pyrites (Scheurer-Kestner, *C. R.* 99, 917; Lunge, *B.* 10, 1824).—3. By passing a mixture of SO_2 and O over heated Pt (Phillips a. Magnus, *P.* 24, 610), spongy Pt (Hodgkinson a. Lowndes, *C. N.* 57, 193), or certain oxides, *e.g.* Fe_2O_3, CuO, Cr_2O_3 (Mahla a. Wöhler, *A.* 81, 255).—4. By heating certain sulphates or bisulphates, *e.g.* $Fe_2(SO_4)_3$, $Bi_2(SO_4)_3$, Ag_2SO_4, or $NaHSO_4$.—5. By distilling Nordhausen sulphuric acid (*v.* Osann, *D. P. J.* 151, 158); also by heating conc. H_2SO_4 with P_2O_5 (Barreswil, *C. R.* 25, 30; Evans, *Ph.* 8, 127).

Preparation.—1. Fuming sulphuric acid is heated at as low a temperature as possible; the impure SO_3 is collected in a dry retort and redistilled once or twice, the most volatile portion being collected each time. The partially purified SO_3 is then distilled into a small tube, c. 8–10 mm. wide and about the length of a finger, containing some dry P_2O_5; this tube is narrowed at one end and fused on to a thick-walled tube c. 1–1·5 mm. wide, which is bent round and fused to a receiving tube c. 12–15 mm. wide and 300 mm. long; the tube containing the SO_3 and P_2O_5 is heated in a water-bath to 90°–100° for 6 or 8 hours, the receiving tube projecting upwards, so that the distillate flows back again into the distilling-tube. The position of the apparatus is then changed, so that the receiving tube is lower than the distilling tube, and the SO_3 is distilled from the P_2O_5 on a water-bath. When sufficient SO_3 has been collected, the narrow connecting tube is fused off, and the SO_3 is kept in the sealed receiving tube (Weber, *B.* 19, 3189).—

2. A mixture of SO_2 and O, in the ratio SO_2:O, is passed over platinised asbestos heated nearly to redness; the SO_3 is condensed in a small dry tube, in which it is sealed up. The mixture of SO_2 and O is obtained by strongly heating conc. H_2SO_4 and removing H_2O ($H_2SO_4 = H_2O + SO_2 + O$) by cooling and passing through coke moistened with 60 p.c. H_2SO_4Aq (Winkler, *D. P. J.* 218, 128). The asbestos is platinised by soaking in $PtCl_4$Aq made alkaline by soda, and mixed with sufficient HCO_2Na to reduce the Pt, drying at 100°, carefully washing out the salts with water, and drying (Thomsen, *B.* 3, 496). The SO_3 thus obtained is not quite pure. It may be purified by distillation with P_2O_5 (*v. supra*).

Properties.—A colourless, mobile liquid, solidifying at c. 15° to long, prismatic, transparent crystals, which melt at 14·8°. According to some observers (*v.* Marignac, *Ar. Ph.* 22, 225; 58, 228; Schultz-Sellack, *P.* 139, 480) the crystals of SO_3 slowly change to a mass of tough, opaque, lustrous needles, which melt above 50°, and constitute a distinct modification of SO_3; but the experiments of Weber (*P.* 139, 480; *B.* 19, 3187; *cf.* Rebs, *A.* 246, 356) have shown that pure SO_3 exists only in one form, and that the substance with higher m.p. is formed by the action of traces of H_2SO_4 in the SO_3; a small trace of moisture suffices to cause the gradual change. SO_3 is very acrid and poisonous; it chars paper, wood, and organic matter generally. SO_3 is extremely hygroscopic; it dissolves in water with a hissing sound and production of much heat ([SO^3,Aq] = 39, 170), forming H_2SO_4Aq. Non-conductor of electricity (Magnus, *P.* 104, 553); not decomposed by electric sparks, but by passing through a red-hot tube gives SO_2 and O. SO_3 does not redden dry litmus. It is a strongly acid-forming oxide (*v.* Sulphuric acid).

Reactions and Combinations.—1. *Heated to redness* (by passing through red-hot tube) gives $SO_2 + O$.—2. Not decomposed by *electric sparks* (Magnus, *P.* 104, 553); *electrolysis* of SO_3 in H_2SO_4 causes separation of S and O, and the solution becomes blue (Geuther, *A.* 109, 129).—3. *Water* reacts violently with SO_3 forming H_2SO_4Aq (*v.* Sulphuric acid).—4. *Hydrogen sulphide* produces H_2SO_4 and S.—5. A mixture of SO_3 and *oxygen*, in the ratio $2SO_3$:O, forms S_2O_7 when submitted to the *silent electric discharge* (Berthelot, *A. Ch.* [5] 14, 345).—6. *Sulphur* dissolves in SO_3 forming S_2O_3; *selenion* and *tellurium* react similarly (*v.* Sulphur thio-oxide, Selenion thio-oxide, and tellurium thio-oxide).—7. *Phosphorus* ignites in vapour of SO_3, forming P_2O_5 and S.—8. *Iodine* dissolves in SO_3, apparently forming several compounds (*v.* Wach, *S.* 50, 37; Schultz-Sellack, *B.* 4, 109), Weber (*J. pr.* [2] 25, 224) describes the compounds $I(SO_3)_3$, $I(SO_3)$, and $I_2(SO_3)$.—9. *Iron* and *zinc* react at red heat to give sulphides and oxides; *mercury* produces sulphate and SO_2 (d'Heureuse, *P.* 75, 255).—10. Several *metallic sulphides*—*e.g.* of Sb, Pb, K—form sulphates and SO_2 when heated with SO_3 (Weber, *P.* 130, 329).—11. Dry *sulphur dioxide* is absorbed by SO_3 at 0°, forming a thin, fuming liquid, approximately $SO_3.2SO_2$ (H. Rose, *P.* 89, 173). According to Schultz-Sellack, liquid SO_2 and SO_3 are miscible in all proportions (*P.* 139, 480). 12. *Selenion dioxide* combines to form $SO_3.SeO_2$ (*v.* Selenion dioxide, *Combinations*, No. 4, p. 441).—13. *Nitric oxide*, in absence of moisture and O, forms $S_2O_9N_2$, which is generally called *nitrosulphonic anhydride* (*q. v.*, p. 601) and written $S_2O_5(NO_2)_2$. *Nitrogen dioxide* (made by heating $Pb(NO_3)_2$) seems to form $SO_3.NO_2$, and on heating this and passing in more NO_2, O is given off and the compound $S_2O_9N_2$ remains (*v.* Weber, *P.* 123, 337; Brüning, *A.* 98, 377). The formula of the first of these compounds is generally doubled, and the compound regarded as $S_2O_5.O.(NO_2)_2$ = *oxynitrosulphonic anhydride* (*q. v.*, p. 601); the second is described in some books as $S_2O_7(NO)_2$ and is called *nitrosyl pyrosulphate*, but from the descriptions of Weber and Brüning it is evidently the same as the compound $S_2O_9N_2$ formed from NO and SO_3, *i.e.* it is *nitrosulphonic anhydride.*—14. SO_3 combines with *iodine pentoxide* to form $3SO_3.I_2O_5$ and $SO_3.5I_2O_5$ (Weber, *B.* 20, 86; Kämmerer, *J. pr.* 83, 72). With *phosphorus pentoxide* $3SO_3.P_2O_5$, decomposing at 30°, is formed (Weber, *B.* 19, 3185; 20, 86). *Arsenious oxide* forms various unstable compounds (Adie, *C. J.* 55, 157; *cf.* Weber, *B.* 19, 3185; Schultz-Sellack, *B.* 4, 109; Reich, *J. pr.* 90, 176; Schafhaütl, *B. J.* 22, 113; and Pearce, *Z. K.* 20, 632). According to Baker (*C. J. Proc.* 1893. 130), dry SO_3 does not react with *dry oxides of barium, calcium, or copper.*—15. The compound $SO_3.N_2O_5.5H_2SO_4$ is said to be formed by passing SO_3 into pure, well-cooled, *nitric acid* (Weber, *P.* 123, 233; 142, 602).—16. *Boric acid* forms $BH_3O_3.3SO_3$ [$= B(HSO_4)_3$] (D'Arcy, *C. J.* 55, 155; *cf.* Merz, *J. pr.* 99, 81; Schultz-Sellack, *B.* 4, 15).—17. *Hydrobromic* and *hydriodic acids* separate Br, and I, and form H_2SO_4 and SO_2.—18. *Hydrochloric* and *hydrofluoric acids* form $Cl(SO_2.OH)$ and $F(SO_2.OH)$ (*v.* Chlorosulphonic acid, p. 599; and Fluosulphonic acid, p. 600). 19. *Conc. sulphuric acid* forms $H_2S_2O_7$ (*v.* Pyrosulphuric acid, p. 625).—20. *Ammonia* produces $NH_2(SO_2.OH)$ and salts of this acid (*v.* Sulphamic acid and salts, p. 567); and also salts of $NH(SO_2.OH)_2$ (*v.* Imidosulphonic acid and salts, p. 600).—21. *Phosphoretted hydrogen* produces SO_2 and red P (H. Rose, *P.* 24, 140; Aimé, *J. pr.* 6, 79).—22. *Phosphorus trichloride* reacts violently, forming $POCl_3$ and SO_2 (Armstrong, *B.* 3, 732; Michaelis, *J. Z.* 6, 239). *Phosphorus pentachloride* produces *pyrosulphuryl chloride* $S_2O_5Cl_2$ (*q. v.* under Sulphur oxychlorides, p. 617).—23. *Boron chloride* reacts at c. 120° to form $S_2O_5Cl_2$ (Prudhomme, *Bl.* [2] 14, 385).—24. *Nitrosyl chloride* (produced by heating *aqua regia*) produces $SO_3.NOCl$ $= NO_2(SO_2Cl)$ (*v.* Nitrosulphonic chloride, p. 601). — 25. *Pyrosulphuryl bromide* $S_2O_5Br_2$ (*q. v.*, p. 617) is perhaps formed by the reaction of *bromoform* with SO_3.—26. *Selenion tetrachloride* produces $SSeO_5Cl_4$ (*v.* Selenion thio-oxychloride, p. 441).

Sulphuric peroxide S_2O_7. (*Sulphur heptoxide. Persulphuric anhydride.*) Mol. w. not known with certainty but probably 175·68 (S_2O_7). This oxide was prepared by Berthelot in 1877 (*A. Ch.* [5] 14, 345) by passing the 'silent' electric discharge, for several hours, through a mixture of SO_3 and O in the ratio $2SO_3$:O, or of SO_2 and O in the ratio $2SO_2$:3O. (For apparatus used *v.* B., *A. Ch.* [5] 12, 463.) Oily drops formed on the sides of the tube, and on reducing the temperature nearly to 0° they solidified to long, white, crystalline, needles. S_2O_7 resembles solid SO_3 in appearance; it remains unchanged in a sealed tube for some days at 0°; when heated it gives SO_3 and O; dissolves in conc. H_2SO_4 forming a fairly stable solution; fumes in the air; in water it rapidly decomposes forming H_2SO_4Aq and giving off a brisk stream of O; with BaOAq forms $BaSO_4$ and O; and also some Ba persulphate, according to Berthelot (*l.c.*; no analyses given). By electrolysing H_2SO_4Aq, containing water and acid in the ratio $10H_2O:H_2SO_4$, B. (*C. R.* 90, 269) obtained a quantity of persulphuric acid ($H_2S_2O_8$; *v.* under SULPHURIC ACID, p. 625) equal to from 88 to 123 g. S_2O_7 per litre; using an acid of the concentration $H_2SO_4:2H_2O$ to $H_2SO_4:3H_2O$, B. (*l.c.*) says that a compound $S_2O_7.2H_2O_2$ is formed, which is decomposed by excess of conc. H_2SO_4 chiefly to $H_2S_2O_8$, and by dilution with water to $H_2S_2O_8Aq$ and H_2O_2Aq which after a time decompose to H_2SO_4Aq, H_2O, and O.

S_2O_7 is the anhydride of *persulphuric acid* $H_2S_2O_8$ (*q. v.*, p. 625). Mendeléeff (*B.* 15, 242) regards S_2O_7 as analogous in constitution to H_2O_2, and writes the formula $\left.\begin{array}{l}OSO_2\\ |\\ OSO_2\end{array}\right>O$; he looks on the corresponding acid as derived from H_2O_2 by replacing 2H by $2SO_2OH$, thus:

$$\begin{array}{l}O.(SO_2.OH)\\ |\\ O.(SO_2.OH)\end{array}$$

According to Traube (*B.* 22, 1518; 24, 1764; 25, 95), the liquid obtained by electrolysing 40 p.c. H_2SO_4Aq contains an oxide to which he gives the formula SO_4 and calls *sulphuryl hyperoxide* (or *holoxide*), $SO_2.O_2$. Traube did not isolate this compound; his argument for its existence is based on the results of indirect analyses. In the light of the criticisms of Carnegie (*C. N.* 64, 158) it may be concluded that the existence of SO_4 is extremely improbable. In a later communication (*B.* 26, 1481) Traube thinks it is probable that SO_4 does not exist.

Sulphur, oxyacids of. For compositions of these acids, and references to articles where they are described, *v.* SULPHUR, OXYACIDS OF (p. 619).

Sulphur, oxyacids of, nitrogen derivatives of. For a general statement regarding these compounds, and references to the articles where they are described, *v.* SULPHUR OXYACIDS, NITROGEN DERIVATIVES OF (p. 619).

Sulphur, oxybromides of. There is very little definite knowledge regarding the compounds of S, O, and Br. According to Michaelis (*J. Z.* 6, 239, 296) PBr_5 does not react with SO_2, and a mixture of PCl_3 and Br (in the ratio PCl_3Br_2) produces $POCl_3$ and S bromides. Rose (*P.* 44, 327) and Clausnizer (*B.* 11, 2012) could not obtain an oxybromide by the reaction of SO_3 and S bromide, nor by the action of SO_2 and HBr.

In his memoir on $S_2O_5Cl_2$ prepared by the reaction of SO_3 with $CHCl_3$, Armstrong (*B.* 2, 712) states that $CHBr_3$ reacts with SO_3 similarly to $CHCl_3$, but he does not describe the product. If the reaction of $CHBr_3$ with SO_3 is strictly similar to that of $CHCl_3$ the product would be *pyrosulphuryl bromide* $S_2O_5Br_2$.

Odling (*C. J.* 7, 2) supposed that *sulphuryl oxy-bromide* SO_2Br_2 was formed by the action of sunlight on SO_2 and Br, but Sestini (*Bl.* [2] 10, 226) and Melsens (*C. R.* 76, 92) failed to obtain an oxybromide by this method.

THIONYL BROMIDE $SOBr_2$. This compound was obtained, but not quite free from S bromides, by Hartog a. Sims (*C. J. Proc.* No. 118, 1893. 10) by the interaction of $SOCl_2$ and NaBr; it is described as a very hygroscopic, crimson liquid, S.G. 2·68 at 18°, decomposing at 150° to Br, S bromides, &c.

Sulphur, oxychlorides of. Five compounds have been isolated, $SOCl_2$, SO_2Cl_2, $S_2O_5Cl_2$, S_2OCl_4, and $S_2O_3Cl_4$.

THIONYL CHLORIDE $SOCl_2$ (*Sulphurous oxy chloride*). Mol. w. 118·62. Boils at 78·8°; S.G. $\frac{0°}{4°}$ 1·67673, S.G. at b.p. 1·52143 (Thorpe, *C. J.* 37, 354; for other data *v.* Carius, *A.* 106, 303; 111, 93; Wurtz, *C. R.* 62, 460). V.D. at c. 150° = 56, at c. 440° = 39 (Heumann a. Köchlin, *B.* 16, 1625). H.F. $[S,O,Cl^2]$ = 40,800; heat of vaporisation = 6,480 (Ogier, *C. R.* 94, 82). S.V. 78·01 (Thorpe, *l.c.*).

Formation.—1. By the reaction of PCl_5 with SO_2 (Kremers, *A.* 70, 297; Schiff, *A.* 102, 111), SO_2Cl_2, $C_6H_5.SO_2Cl$, and several other organic compounds containing S (*v.* Kekulé a. Barbaglia, *B.* 5, 875; Carius, *J. pr.* [2] 2, 262), sulphites, or thiosulphates; also by the reaction of $POCl_3$ with sulphates.—2. By the action of Cl_2O on CS_2, or on S in S_2Cl_2 at −12° (Wurtz, *C. R.* 62, 460).—3. By the interaction of SO_3 and SCl_4 (Michaelis a. Schifferdecker, *B.* 5, 924; 6, 993).—4. Along with SO_2Cl_2 by the gradual decomposition of $S_2O_3Cl_4$ (*q. v.*, p. 619).

Preparation.—1. About 100 g. dry PCl_5 are placed in a retort connected with a reversed condenser, and a stream of dry SO_2 is led in till the PCl_5 has liquefied; another 100 g. PCl_5 is added and the stream of SO_2 is continued; when sufficient PCl_5 has thus been decomposed ($PCl_5 + SO_2 = SOCl_2 + POCl_3$) the liquid is heated for some time (the reversed condenser being still attached) to get rid of SO_2, and then fractionated repeatedly ($SOCl_2$ boils at 78·8° and $POCl_3$ at 107·2°) (Carius, *A.* 106, 303; 111, 93; Wurtz, *A.* 139, 375; Michaelis, *A.* 170, 1; Thorpe, *C. J.* 37, 354).—2. S_2Cl_2 is placed in a small flask, cooled to c. −20°, a stream of dry Cl is led in till the liquid is saturated, and then SO_3 is distilled into the flask from a solution in conc. H_2SO_4; the weights of S_2Cl_2 and SO_3 used should be in the ratio $S_2Cl_2:4SO_3$ (= 1:2·37); convenient quantities to use are 22 g. S_2Cl_2 and 50 g. SO_3. ($SCl_4 + 2SO_3 = SOCl_2 + S_2O_5Cl_2$). The liquid is fractionated finally from a small quantity of SO_3 (Michaelis a. Schifferdecker, *B.* 5, 924; 6, 993).

Properties.—A colourless, very refractive liquid, fuming in the air, with a very penetrating odour; vapour attacks the eyes and respiratory organs. V.D. 56 at c. 150°, but 39 at c. 440°; the smaller value corresponds with the decomposition $4SOCl_2 = S_2Cl_2 + 2SO_2 + 3Cl_2$; these products are obtained by passing vapour of $SOCl_2$ through a red-hot tube (Heumann a. Köchlin, *B.* 16, 1625).

Reactions and Combinations.—1. *Moist air* produces HCl and SO_2.—2. *Water* also forms HClAq and SO_2, warm water forming in addition H_2SO_4Aq and S (Carius, *l.c.*).—3. *Hydrogen sulphide* produces SO_2, HCl, and S (Prinz, *A.* 223, 371).—4. *Phosphorus pentasulphide* reacts to form SO_2, $PSCl_3$, and S, and some S_2Cl_2 (Prinz, *l.c.*).—5. With *antimony trisulphide* the products are $SbCl_3$, SO_2, and S.—6. *Sulphur*, heated to 180° with $SOCl_2$, forms S_2Cl_2 and SO_2; *selenion* forms S_2Cl_2 and $SSeCl_2$ (Prinz, *l.c.*).—7. Powdered *antimony* reacts without heating, forming $SbCl_3$, Sb_2S_3, and SO_2.—8. $POCl_3$, $PSCl_3$ and PCl_5 are formed by heating $SOCl_2$ with *phosphorus trichloride* (Michaelis, *J. Z.* 6, 239).—9. Heating with *sulphur dichloride* produces S_2OCl_4 (*q. v.*, p. 619) (Ogier, *Bl.* [2] 37, 293).—10. *Ammonia* does *not* produce thionylamide $SO(NH_2)_2$, but forms NS, NH_4Cl, $(NH_4)_2SO_3$, and NH_4 polythionates (M., *l.c.*).—11. Reacts rapidly with *silver nitrate*, forming $NO_2(SO_2.Cl)$ (Thorpe, *C. J.* 41, 297).—12. $SOCl_2$ absorbs *sulphur dioxide* and *chlorine* freely (M., *l.c.*).—13. For reactions with various *organic compounds v.* Michaelis (*l.c.*); Heumann a. Köchlin (*B.* 16, 1625); Böttinger (*B.* 11, 1407).

SULPHURYL CHLORIDE SO_2Cl_2 (*Sulphuric oxychloride*). Mol. w. 134·58. Boils at 69·95° (Thorpe, *C. J.* 37, 359; for other determinations *v.* Regnault, *J. pr.* 19, 243; Clausnizer, *B.* 11, 2010; Ogier, *C. R.* 94, 82). S.G. $\frac{0^{\circ}}{4^{\circ}}$ 1·70814; at b.p. 1·56025 (Thorpe, *l.c.*). V.D. 65 at 184°; 34 at 440° (Heumann a. Köchlin, *B.* 16, 602; *cf.* Regnault, *J. pr.* 18, 97; Behrend, *J. pr.* [2] 15, 23). S.V. 86·29 (Thorpe, *l.c.*, p. 372). H.F. $[S,O^2,Cl^2]=89{,}780$; $[SO^2,Cl^2]=18{,}700$ (*Th.* 2, 310; *cf.* Ogier, *C. R.* 94, 82). S.H. (15°–63°) ·233 (Ogier, *l.c.*). Heat of vaporisation 7,060 (O., *l.c.*).

Formation.—1. By the direct combination of SO_2 and Cl in sunlight, or by reacting on a mixture of C_2H_4 and SO_2 by Cl in sunlight (Regnault, *J. pr.* 18, 93; 19, 243). Schulze (*J. pr.* [2] 23, 351; 24, 168) recommends to allow SO_2 and Cl to react in presence of camphor. Melsens (*C. R.* 76, 92) passes SO_2 and Cl into glacial acetic acid.—2. By passing SO_3 over charcoal saturated with Cl (M., *l.c.*).—3. By the interaction of PCl_5 with H_2SO_4 or SO_3 (Williamson, *P. M.* [4] 7, 365; Schiff, *A.* 102, 111); according to Michaelis (*J. Z.* 6, 233, 292), SO_3 and PCl_5 form $S_2O_5Cl_2$.—4. By heating SO_3 and BCl_3, in the ratio $2SO_3:BCl_3$, to 120° in a closed tube (Gustavson, *B.* 6, 9).—5. By heating $Cl(SO_2.OH)$ to c. 200° for some time (Behrend, *B.* 8, 1004; *cf.* Otto a. Beckurts, *B.* 11, 2058).

Preparation.—1. Cl and SO_2 are passed into camphor, and the colourless liquid is fractionated (Schulze, *l.c.*).—2. $Cl(SO_2.OH)$ (*v.* CHLOROSULPHONIC ACID, p. 509) is heated to c. 200°, in a closed tube, for some hours, when it decomposes thus, $2[Cl(SO_2.OH)]=SO_2Cl_2+H_2SO_4$; the liquid is distilled, the portion coming over at 67°–71° being collected separately and then repeatedly fractionated (Behrend, *l.c.*; *cf.* Thorpe, *l.c.*).

Properties and Reactions.—A colourless liquid, fuming slightly in air. 1. Decomposed by *heating* to dull redness into SO_2 and Cl; decomposition is complete at 440° (Heumann a. Köchlin, *B.* 16, 602); but does not begin at 250° (Beckurts a. Otto, *B.* 11, 2060).—2. *Water* produces HClAq and H_2SO_4Aq; a small quantity of water is said to form $Cl(SO_2.OH)Aq$.—3. Excess of SO_2Cl_2 added to a little *alcohol* forms $Cl(SO_2.OEt)$; with excess of alcohol $SO_2(OEt)_2$ is produced (Behrend, *B.* 9, 1334).—4. *Phosphorus pentachloride* reacts to form $POCl_3$, $SOCl_2$, and Cl (H. a. K., *B.* 15, 1736).—5. *Phosphorus*, *arsenic*, and *antimony* produce PCl_3, $AsCl_3$, and $SbCl_3$ respectively, and SO_2 (H. a. K., *l.c.*).—6. *Ammonia* forms NH_4Cl and $SO_2.NH_2.ONH_4$.—7. With many *organic compounds* SO_2Cl_2 reacts like PCl_5 or $POCl_3$, substituting Cl for H (*v.* Dubois, *Z.* [2] 2, 705; Michaelis, *A.* 170, 1).

PYROSULPHURYL CHLORIDE $S_2O_5Cl_2=Cl.SO_2.O.SO_2.Cl$. (*Disulphuryl chloride. Pyrosulphuric oxychloride. Chlorosulphonic anhydride.*) Mol. w. 214·38. Boils at 139·59° (Thorpe, *C. J.* 37, 360; for other determinations *v.* Rose, *P.* 44, 291; Michaelis, *J. Z.* 6, 235, 240, 292; Rosenstiehl, *C. R.* 53, 658; Schützenberger, *C. R.* 69, 352). S.G. $\frac{0^{\circ}}{4^{\circ}}$ 1·85846, at b.p. 1·60610 (Thorpe, *l.c.*). V.D. at slightly above b.p. = 104; between 160° and 240° = 54·8 (Heumann a. Köchlin, *B.* 16, 479; Kanowaloff, *B.* 16, 1127; *cf.* Rosenstiehl, *C. R.* 53, 658; Rose, *P.* 44, 291; Ogier, *C. R.* 94, 82, 217; 96, 648). H.F. $[S^2,O^5,Cl^2]=180{,}600$ (Kanowaloff, *l.c.*); Ogier (*l.c.*) gives 159,400. Heat of vaporisation 7,570 (K., *l.c.*); 13,160 (O., *l.c.*). S.H. ·258 (K., *l.c.*).

Formation.—1. By the interaction of PCl_5 and SO_3 or $Cl(SO_2.OH)$.—2. By heating P_2O_5 and $Cl(SO_2.OH)$ (Billitz a. Heumann, *B.* 16, 483).—3. By heating SO_3 with NaCl (R., *l.c.*), with S_2Cl_2 (Rose, *P.* 44, 291), with CCl_4 (Schützenberger, *C. R.* 69, 352; Kanowaloff, *C. R.* 95, 1284), with C_2Cl_6 (Prudhomme, *C. R.* 70, 1137), with $CHCl_3$ (Armstrong, *C. J.* [2] 1, 244), or with $SiCl_4$ (Gustavson, *B.* 5, 332).—4. By the interaction of $POCl_3$ and $SOCl_2$ (Michaelis, *J. Z.* 6, 235, 240, 292).

Preparation.—1. P_2O_5 and $Cl(SO_2.OH)$ are heated in a flask with a reversed condenser, using rather more $Cl(SO_2.OH)$ than P_2O_5; when HCl and SO_2 cease to be given off, the liquid is distilled, and the portion coming over between 135° and 145° is fractionated (B. a. H., *l.c.*).—2. S_2Cl_2 in a flask is surrounded by a freezing mixture, and saturated with SO_3; the product is fractionated; $5SO_3+S_2Cl_2=5SO_2+S_2O_5Cl_2$ (Rose, *P.* 44, 291). Thorpe (*C. J.* 37, 360) found that the product of this reaction boiled almost wholly between 135° and 138°.

Properties and Reactions.—A colourless, mobile, very refractive liquid, fuming in the air with formation of $Cl(SO_2.OH)$.—1. Decomposed by *heat* to SO_3, SO_2, and Cl (Rose, *P.* 44, 291); the V.D. determinations of Heumann a. Köchlin (*B.* 16, 479) show that at 440° the decomposition is $S_2O_5Cl_2=SO_3+SO_2+Cl_2$.—2. Sinks in *water*, and is slowly decomposed to HClAq and H_2SO_4Aq; if a very little water is used $Cl(SO_2.OH)$ is formed, thus $S_2O_5Cl_2+H_2O=2Cl(SO_2.OH)$ (*v.* B. a. H., *l.c.*)—3. Reacts with *phosphorus*, *sulphur*, *antimony*, *copper*, *iron*, *zinc*, and some other *metals*, to produce chlorides, SO_3 and SO_2 (Heumann a. Köchlin, *B.* 16, 479).—4. *Phosphorus trichloride* produces

PCl_3, $POCl_3$, and SO_2; *phosphorus pentachloride* forms $POCl_3$, Cl, and SO_2 (Geuther, *B.* 5, 925). 5. *Selenion tetrachloride* gives $SSeO_3Cl_4$ (Clausnizer, *B.* 11, 2010).—6. *Chromates* react to form CrO_2Cl_2 (Rosenstiehl, *C. R.* 53, 658).—7. *Ammonia* forms a white solid, which dissolves in water, producing NH_4Cl and a sulphamate of NH_4 (Rose, *l.c.*).

Sulphur monoxytetrachloride S_2OCl_4. By heating equal weights of S_2Cl_2 and SO_2Cl_2 to 250° in a sealed tube, Ogier (*Bl.* [2] 37, 293) obtained a deep-red liquid resembling S_2Cl_2, S.G. 1·656 at 0°, decomposing under 100° to S_2Cl_2, SO_2, and S, to which he gave the composition S_2OCl_4. Decomposed by water to H_2SO_4Aq, SO_2Aq, HClAq, thionic acids, and S.

Sulphur tri-oxytetrachloride $S_2O_3Cl_4$. Mol. w. not determined. This compound was obtained by Millon (*A. Ch.* [3] 29, 327) by the action of moist Cl on S_2Cl_2 (*cf.* Marchand, *J. pr.* 22, 507; Carius, *A.* 106, 295). It is conveniently prepared by the reaction $SCl_4 + Cl(SO_2.OH) = HCl + S_2O_3Cl_4$; a stream of dry Cl is led into a mixture, in the ratio of equal numbers of molecules, of S_2Cl_2 and $Cl(SO_2.OH)$, kept at c. −20°, until a semi-solid mass is obtained (a very wide tube must be used to lead in Cl); the temperature is then kept at c. −13° and the Cl is continued till the mass gets quite solid; the freezing mixture is then removed, and the Cl is continued till the mass is white, when the excess of Cl is removed by a stream of dry CO_2 (Michaelis a. Schifferdecker, *B.* 6, 996).

$S_2O_3Cl_4$ is a white, crystalline solid, with a most disagreeable odour; the vapour acts on the eyes. Melts at 57°, giving off SO_2 and Cl, and leaving a liquid that solidifies chiefly to $SOCl_2$ and $S_2O_5Cl_2$; a portion sublimes in fine white needles. Ice-cold water produces SO_2Aq, H_2SO_4Aq, and HClAq; water at the ordinary temperature also separates S. Deliquesces in a partially closed vessel, giving off HCl, Cl, and SO_2, and leaving a liquid that gives $SOCl_2$ and $S_2O_5Cl_2$ on distillation. Conc. H_2SO_4 reacts violently, forming HCl, SO_2, and $Cl(SO_2.OH)$; CS_2 produces very rapid decomposition to $COCl_2$, CO, SO_2, S_2Cl_2, and $SOCl_2$. On long standing in a closed tube $S_2O_3Cl_4$ separates into equal numbers of molecules of $SOCl_2$ and SO_2Cl_2 (M. a. Mathias, *B.* 6, 1452).

SULPHUR, OXYACIDS OF. Several acids have been isolated, and salts of some others are known. The following list gives the names and compositions of the oxyacids of sulphur and their salts, with references to the articles where these compounds are described:—

Hyposulphurous acid and salts $H_2S_2O_4$ and $M_2S_2O_4$; *v. Hyposulphurous acid* under Sulphurous acid (p. 627), and *hyposulphites* under Sulphites (p. 592).

Sulphurous acid and salts H_2SO_3, $MHSO_3$, and M_2SO_3; *v.* Sulphurous acid (p. 626), and Sulphites (p. 587).

Sulphuric acid and salts H_2SO_4, $MHSO_4$, and M_2SO_4; *v.* Sulphuric acid (p. 620) and Sulphates (p. 567).

Thiosulphuric acid and salts $H_2S_2O_3$, MHS_2O_3, and $M_2S_2O_3$; *v.* Thiosulphuric acid (p. 708) and Thiosulphates (p. 705).

Thionic acids and salts $H_2S_2O_6$, $H_2S_3O_6$, $H_2S_4O_6$, $H_2S_5O_6$ (and salts); *v.* Thionic acids (p. 698) and Thionates (p. 695).

Pyrosulphuric acid and salts $H_2S_2O_7$, MHS_2O_7, and $M_2S_2O_7$; *v. Pyrosulphuric acid* under Sulphuric acid (p. 625), and *Pyrosulphates* under Sulphates (p. 583).

Persulphuric acid and salts $H_2S_2O_8Aq$, $M_2S_2O_8$, and MS_2O_8; *v. Persulphuric acid* under Sulphuric acid (p. 625), and *Persulphates* under Sulphates (p. 582). M. M. P. M.

SULPHUR OXYACIDS, NITROGEN DERIVATIVES OF. In 1845 Fremy (*A. Ch.* [3] 15, 408) described the K salts of a number of acids obtained by the interaction of KNO_2Aq and K_2SO_3Aq, and by boiling the products of this interaction with slightly acidified water; he called the compounds *salts of sulphazotised acids*. The examination of these salts was prosecuted by Claus a. Koch (*A.* 152, 336 [1874], and by Claus (*A.* 158, 52, 194 [1876]); Berglund (*Bl* [2] 25, 455; *B.* 9, 252, 1896 [1875]); and Raschig (*A.* 241, 161; *B.* 20, 584 [1887]) also investigated the sulphazotised acids of Fremy; and the researches of Divers and Haga (*C. J. Trans.* 1885. 1886. 1889. 1892) have thrown much light on many classes of these compounds. The more recent investigations noted above have shown many of the formulæ given by Fremy to be inaccurate, and they have also led to a considerable revision of Claus's results. As the compounds that have been fairly thoroughly examined are noticed under the heading Sulphonic acids and derivatives (p. 509), it does not seem necessary to give an account of the other *salts of sulphazotised acids*, especially as it is very probable that the formulæ assigned to these compounds will require modification, and that some of the compounds will be found not to exist.

The chief *sulphazotised compounds* that have been investigated sufficiently to establish their composition satisfactorily are the following:—

Amidosulphonic acid and salts $NH_2(SO_2.OH)$; described as Sulphamic acid (p. 567).

Imidosulphonic acid and salts $NH(SO_2.OH)_2$ (p. 600).

Nitrilosulphonates $N(SO_2.OM)_3$ (p. 601).

Nitrosulphonic acid and salts $NO_2(SO_2.OH)$ (p. 601).

Nitrosulphonic anhydride $(NO_2)_2S_2O_5$ (p. 601).

Nitrosulphonic chloride $NO_2(SO_2.Cl)$ (p. 601).

Nitroso-oxy-amidosulphonates $N(NO.OH)(SO_2.OM)$; described as *nitrososulphates* under Sulphates (p. 581).

Oxy-amidosulphonic acid and salts (and salts derived therefrom) $NH(OH)(SO_2.OH)$ (p. 602).

Oxy-imidosulphonates (and salts derived therefrom) $N(OH)(SO_2.OM)_2$ (p. 602).

Oxy-nitrosulphonic anhydride $(NO_2)_2.O.S_2O_2$ (p. 601).

Sulphamide $(NH_2)_2SO_2$ (p. 567).

Sulphimide $NH.SO_2$ (p. 587).

Sulphimido-amide $NH(SO_2.NH_2)_2$ (p. 587).

Thionamic acid and salts $NH_2(SO.OH)$ (p. 695). M. M. P. M.

SULPHURETTED HYDROGEN *v.* HYDROGEN SULPHIDE, vol. ii. p. 725.

SULPHURIC ACID; also **PERSULPHURIC ACID** and **PYROSULPHURIC ACID.**

SULPHURIC ACID H_2SO_4 (*Oil of vitriol*). Mol. w. probably 97·76. Melts at 10·35° (Pickering, *C. J.* 57, 331); 10·5° (Thilo, *Chem. Zeitung*, 16, 1688). Boiling begins at c. 290°, SO_3 and H_2O with some $H_2SO_4.xH_2O$ passing off; b.p. rises till 338° is reached, when it becomes constant and complete dissociation to SO_3 and H_2O occurs; for b.p. of H_2SO_4Aq from 95 to 5 p.c. H_2SO_4 *v.* Lunge (*B.* 11, 370). S.G. $\frac{15°}{15°}$ 1·8884 (Perkin, *C. J.* 63, 59; *cf.* Pickering, *C. J.* 57, 73, *note*; Kohlrausch, *W.* 17, 69; Schertel, *J. pr.* [2] 26, 246; Mendeléeff, *B.* 17, 30, 2536; Lunge a. Isler, *Zeit. für anorg. Chemie*, 1890. 129). V.D. 25 at 440°, corresponding with dissociation to $SO_3 + H_2O$ (Deville a. Troost, *C. R.* 56, 891; Wanklyn a. Robinson, *Pr.* 12, 507). S.H. (22° to 80°) ·355; (22° to 170°) ·37 (Pfaundler, *B.* 3, 798); (16° to 20°) ·3315 (Marignac, *Ar. Sc.* 39, 217, 273). C.E. ·0005585 at 20° (Marignac, *l.c.*). H.F. $[H^2,S,O^4] = 192{,}920$; $[H^2O, SO^3] = 21{,}320$ (formation of liquid H_2SO_4) (*Th.* 2, 255). Heat of fusion = 860 g. units (for 98 g. H_2SO_4) (Berthelot, *C. R.* 78, 716). T. C. *v.* Beetz (*W.* 7, 435), Weber (*J.* 1885. 121). $\frac{\mu-1}{d}$. Mol. w. = 32·45 (Gladstone, *P. M.* [4] 36, 311). For further data *v. infra.*

Occurrence.— Small quantities of H_2SO_4, from ·1 to ·5 p.c., are found in some rivers and springs in volcanic districts; in a pool in Texas, Mallet (*C. N.* 26, 147) found 5·29 g. H_2SO_4 per litre of water. The acid is also found in certain animal secretions; the salivary glands of some molluscs are said to contain c. 2 p.c. (Bödeker a. Troschel, *B. B.* 1854. 486; De Luca a. Panceri, *Bl.* [2] 9, 400; Maly, *M.* 1, 205). The salts of sulphuric acid occur in large quantities (*v.* SULPHATES, p. 567).

Formation.—The formation of an oily liquid by heating alum is spoken of by Geber in the eighth century; a similar liquid was formed in the fifteenth century by burning sulphur with saltpetre. These liquids were shown to be identical towards the end of the sixteenth century. Oil of vitriol seems to have been manufactured in fair quantities by heating ferrous sulphate from about the early part of the eighteenth century; the first manufactory for making the acid from sulphur was started at Richmond by Ward about 1740. The composition of sulphuric acid was determined by Lavoisier.

1. By long exposure of flowers of sulphur in the air (John, *S.* 14, 417; Wagenmann, *P.* 24, 601).—2. By heating S with H_2O to c. 200°; by electrolysing H_2O, using Pt electrodes with pieces of S attached, the H_2SO_4 forms at the positive pole (Becquerel, *C. R.* 56, 237).—3. By the oxidation of S in presence of H_2O by Cl, HNO_3, HCl and $KClO_3$, *aqua regia*, &c.; also by certain metallic salts (*v.* Wicke, *A.* 82, 146; Parkmann, *Am. S.* [2] 33, 328).—4. By oxidising SO_2Aq or SO_2 in presence of water, by Cl, Br, H_2O_2Aq, NO_2, HNO_3, &c.; by passing moist SO_2 and air over hot Pt black (Phillips, *A.* 4, 171), through a red-hot tube containing pieces of glass (Magnus, *P.* 24, 610), or over red-hot sand (Blondeau, *C. R.* 29, 405).—5. By the oxidation of H_2S and polythionic acids (*v.* Cloëz a. Guignet, *C. R.* 46, 1110).—6. By the interaction of water and SO_3, SO_2Cl_2, $SO_2.Cl.OH$, &c.

Preparation.—Commercial oil of vitriol is diluted until the S.G. is 1·53 (= 50° Beaumé, or 106° Twaddell, = 62·5 p.c. H_2SO_4 by weight); the acid is heated to 70°–80°, and $Na_2S_2O_3$ is added in quantity sufficient to decompose the As_2O_3 present (which should be estimated beforehand), according to the equation $3Na_2S_2O_3 + As_2O_3 = 3Na_2SO_4 + As_2S_3$; the acid is stirred until the As_2S_3 separates in flocks (Thorn, *D. P. J.* 217, 495); the acid is filtered from As_2S_3 through asbestos or glass-wool, and is then concentrated by evaporation in a Pt dish till it begins to fume, and then in a retort of Pt or hard glass. The conc. acid is now heated with a little pure $(NH_4)_2SO_4$, whereby HNO_2 and HNO_3 are decomposed ($NH_4.NO_2$ and $NH_4.NO_3$ are formed, and then decomposed to N and H_2O, and N_2O and H_2O). The acid is then distilled from a glass retort, heated by a ring-burner placed around the retort at about two-thirds of the distance from the level of the acid to the bottom of the retort. The distillate is re-distilled in small quantities from a Pt retort into a Pt receiver; the condenser being formed of Pt tubes, soldered with gold and fitting closely one into the other, and the temperature being such that the acid does not boil during the distillation (*cf.* Stas, *Chem. Proport.* 112). Various other methods for removing As have been proposed; for the preparation of H_2SO_4 free from As for chemico-medical use *v.* Bloxam (*C. J.* 15, 52), also Buignet a. Bussy (*J. Ph.* [3] 44, 177; 46, 252).

Commercial oil of vitriol is prepared by passing SO_2, mixed with a little HNO_3, into large leaden chambers into which jets of steam are also sent. The SO_2 is prepared by burning S or pyrites in a stream of air; the hot gas is passed over HNO_3, or over pots containing KNO_3 and H_2SO_4, so that it sweeps into the leaden chambers a certain quantity of HNO_3. The interactions between the hot SO_2 and HNO_3 probably produce NO and N_2O_3 ($3SO_2 + 2HNO_3 + 2H_2O = 3H_2SO_4 + 2NO$; and also $2SO_2 + 2HNO_3 + H_2O = 2H_2SO_4 + N_2O_3$); the NO then combines with O in the air of the chambers to form N_2O_3 ($4NO + O_2 = 2N_2O_3$), which interacts with SO_2 and H_2O to produce H_2SO_4 and NO ($N_2O_3 + SO_2 + H_2O = H_2SO_4 + 2NO$):—if N_2O_3 is produced in the primary reaction of SO_2 with HNO_3, this N_2O_3 may take up O to form N_2O_4, which in turn may react with SO_2 and H_2O to produce H_2SO_4 and NO ($N_2O_4 + 2SO_2 + 2H_2O = 2H_2SO_4 + 2NO$). These cycles of changes proceed as long as SO_2 is sent into the chambers, and there is present a sufficiency of O, H_2O, and oxides of N. If there is not sufficient H_2O present to complete the decomposition of N_2O_3 and SO_2 (or N_2O_4 and SO_2) to H_2SO_4 and NO, nitrosulphonic acid—$NO_2(SO_2.OH)$—is formed as a solid on the sides of the chamber ($3N_2O_3 + 2SO_2 + H_2O = 2NO_2(SO_2.OH) + 4NO$; or $3N_2O_4 + 4SO_2 + 2H_2O = 4NO_2(SO_2.OH) + 2NO$);

when steam is now sent into the chamber the nitrosulphonic acid is decomposed to H_2SO_4 and N_2O_3 ($2NO_2(SO_2.OH) + H_2O = 2H_2SO_4 + N_2O_3$). It is possible that the formation of $NO_2(SO_2.OH)$ and the interaction of this with water may form normal stages in the series of reactions that occur in the chambers. Lunge (*C. J.* 47, 465) regards N_2O_3 as the chief carrier of O from the air to the SO_2; he formulates the two main interactions as

(1) $2SO_2 + N_2O_3 + O_2 + H_2O = 2NO_2(SO_2.OH)$,
(2) $2NO_2(SO_2.OH) + H_2O = 2H_2SO_4 + N_2O_3$;

moreover, he insists that the interactions take place for the most part between gases in contact with the surface of the vesicles of liquid water formed by the condensation of the steam sent into the chamber. (A fuller discussion of the reactions that occur in the leaden chambers will be found in the DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 726.)

Some portion of the oxides of N is swept through the chambers and so lost (part of this is recovered in the Gay-Lussac towers); some is lost by leakage, solution in the acid formed in the chambers, and in other mechanical ways; but some portion of the available oxides of N is also destroyed by secondary reactions that occur in the chambers, and result in the formation of N_2O and sometimes of N or NH_3 (*v.* Weber, *P.* 130, 329; Pelouze, *A. Ch.* [2] 60, 162; Lunge, *B.* 14, 2196; *cf.* DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 729).

Properties.—A clear, colourless, oily, hygroscopic liquid; solidifying at c. 10·5°. The liquid may be cooled much below its freezing-point without solidifying, but addition of a crystal of H_2SO_4 or a small quantity of SO_3 causes crystallisation; the presence of a trace of water lowers the freezing-point to c. 0°. H_2SO_4 is exceedingly acrid and burning, and is a violent poison. H_2SO_4 fumes very slightly in air at the ordinary temperature; at 30°-40° it fumes much, giving off SO_3; according to Colefax (*C. N.* 63, 179), H_2SO_4 is probably slightly volatilised at ordinary temperatures. The mol. w. of H_2SO_4 has not been determined directly, but from the mol. weights of such derivatives as SO_2Cl_2, $SO_2(OMe)_2$, &c., the formula H_2SO_4 is most probably molecular. H_2SO_4 is decomposed when heated, and does not show a definite b.p.; boiling begins at c. 290°, and the temperature gradually rises to 338°, at which temperature dissociation to H_2O and SO_3 is complete. The residue has the composition $H_2SO_4.\frac{1}{12}H_2O$; acid with this composition is obtained by boiling down either $H_2SO_4.xH_2O$ or $H_2SO_4.xSO_3$ (Marignac, *A. Ch.* [3] 39, 184; Dittmar, *C. J.* [2] 7, 446). The sp.gr. of the vapour given off at c. 440° corresponds with that calculated for the dissociation of H_2SO_4 into $SO_3 + H_2O$ (Deville a. Troost, *C. R.* 56, 891; Wanklyn a. Robinson, *Pr.* 12, 507). The b.p. of H_2SO_4Aq, containing from 95 p.c. H_2SO_4 (b.p. = 295°), to 5 p.c. H_2SO_4 (b.p. 101°) is given by Lunge (*B.* 11, 370). H_2SO_4 freezes at 10·352° (*v.* Pickering, *C. J.* 57, 331; where a long series of determinations is given of f.p. of H_2SO_4Aq containing from ·005 to 100 p.c. H_2SO_4). The S.H. and mol. heat (= S.H. × 98) are given by Pfaundler (*B.* 3, 798) as follows:

Temp. interval from 22° to	S.H.	Mol. heat.
80°	·355	34·790
90	·356	34·888
100	·358	35·084
110	·359	35·182
120	·360	35·280
130	·362	35·476
140	·364	35·672
150	·365	35·770
160	·367	35·966
170	·370	36·260

For S.H. of $H_2SO_4.xH_2O$ from 16° to 20°, varying from 0 to 400, *v.* Marignac (*Ar. Sc.* 3 217, 273); Bode (*Zeit. für anorg. Chemie*, 188. 244) gives S.H. of H_2SO_4Aq from S.G. 1·842 to 1·037; Pickering (*C. J.* 57, 160) gives S.H. of H_2SO_4Aq from c. ·2 to c. 12 p.c. H_2SO_4 dissolves in water in all proportions; much heat is produced, and contraction occurs; for thermal measurements *v.* Thomsen (*Th.* 3, 44), Favre a. Silbermann (*C. R.* 24, 1081), F. a. Quaillard (*C. R.* 50, 1150), Pfaundler (*J.* 1869. 122), and, especially, Pickering (*C. J.* 57, 164). According to Pickering (*C. N.* 64, 14), the maximum contraction, calculated for unit weight of solution, changes from 67 p.c. at 8°, to 70·1 p.c. at 38°; but the maximum is constant at 76 p.c., from 8° to 38°, if calculated for unit volume; for fuller data *v.* P. (*C. J.* 57, 148). The expansion of $H_2SO_4.xH_2O$, at 20°, when x varies from 0 to 400, is given by Marignac (*Ar. Sc.* 39, 217, 273). The refractive indices and dispersion of H_2SO_4Aq containing from 93·87 to ·088 p.c. H_2SO_4 are given by Pickering (*C. J.* 63, 99; *cf.* van der Willingen, *Ar. N.* 3, 122). Perkin (*C. J.* 63, 57) gives Mol. R. for H_2SO_4Aq from 99·92 to 9·18 p.c. H_2SO_4 (= from $H_2SO_4 + 53·87\ H_2O$ to $H_2SO_4 + ·004\ H_2O$).

The electrical conductivities of H_2SO_4Aq of different concentrations have been measured by Kohlrausch (*P.* 154, 215; 159; 233; *W.* 6, 1; 17, 69), also by Pickering (*C. J.* 57, 158), who gives determinations for H_2SO_4Aq containing from 1 to 100 p.c. H_2SO_4 (*v.* also Bouty, *C. R.* 108, 393; also Grotrian, *P.* 151, 378).

The S.G. and composition of H_2SO_4Aq of varying concentrations have been determined by many observers. Pickering (*C. J.* 57, 152) gives S.G. and composition of H_2SO_4Aq containing from ·5 to 100 p.c. H_2SO_4 at 0°, 2°, 4°, and each 2° up to 40°. Lunge a. Isler (*Zeit. für anorg. Chemie*, 1890. 129) give the following tables (*cf.* Mendeléeff, *Z. P. C.* 1887. 273; Pickering, *C. N.* 64, 311; Lunge, *C. N.* 65, 13):—

For the properties of fuming H_2SO_4 *v.* PYROSULPHURIC ACID, p. 625.

For a test for small quantities of free H_2SO_4 *v.* Carey Lea (*Am. S.* [3] 45, 478; abstract in *C. J.* 64 (ii.), 566).

Reactions.—1. Conc. H_2SO_4 is decomposed by *heat*; at c. 440° the products are SO_2 and H_2O, and by passing through a red-hot tube SO_2, O, and H_2O are formed (Deville a. Troost, *C. R.* 56, 891; Wanklyn a. Robinson, *Pr.* 12, 507; Redwood, *Ph.* [2] 5, 601; Deville a. Debray, *A. Ch.* [3] 61, 125).—2. Decomposed by the *electric current*; with conc. H_2SO_4 and a raised temperature O separates at the positive pole, and H and S at the negative; at 0° only H and O are given off (Faraday, *T.* 1834; Warburg, *P.* 135, 114; Luckow, *Fr.* 1880. 1; Berthelot, *C. R.* 86, 71; 90, 269). Gladstone a. Tribe (*C. J.* 35, 176; 43, 345) found that a little SO_2 was formed when the electrolysis of 98·2 p.c. H_2SO_4 was very slow. According to the concentration of the H_2SO_4Aq electrolysed, the strength of the current, and the current density, ozone, H_2O_2, and S_2O_7 are formed, besides H and O. For an examination of the conditions favourable to the production of ozone *v.* McLeod (*C. J.* 49, 591, where references are given to earlier memoirs). According to Bouty (*C. R.* 108, 393), acid of the concentration $H_2SO_4 + H_2O$ always gives H_2O_2 on electrolysis; Richarz (*A. Ch.* [2] 24, 183) says that the maximum production of H_2O_2 is obtained with acid of the concentration $H_2SO_4 + 1·347H_2O$; with acid more dilute than 60 p.c. H_2SO_4 very little H_2O_2 is obtained, but considerable quantities of S_2O_7 and ozone (Bouty, *l.c.*; *cf.* Kuriloff, *J. R.* 23, 235). In connection with the electrolysis of H_2SO_4Aq, and the conditions of production of H and O only, or of H_2O_2, ozone, and S_2O_7 also, *v.* Armstrong (*C. J. Proc.* 1893–4. 188 [No. 127]).—3. By passing a mixture of the vapour of H_2SO_4 mixed with *hydrogen* through a red-hot tube, H_2O is obtained along with SO_2, S, or H_2S, according to the quantity of H (*v.* Warner, *C. N.* 28, 13). *Hydrogen occluded by palladium or platinum* partially reduces 98·2 p.c. H_2SO_4, giving SO_2 (G. a. T., *l.c.* p. 177).—4. SO_2, CO_2, and H_2O are formed by heating conc. H_2SO_4 with *carbon*; and SO_2 and H_2O by heating with *sulphur*.—5. *Phosphorus* takes fire in boiling H_2SO_4 with separation of S; *red phosphorus* reacts with the conc. acid when hot, forming SO_2 and H_3PO_4.—6. *Chlorine* reacts with conc. H_2SO_4 to form $Cl(SO_2.OH)$ (*v.* CHLOROSULPHONIC ACID, p. 509).—7. Most *metals* interact; K and Na give off H, Zn and Fe and several other metals also give off H with more or less dilute H_2SO_4Aq at ordinary temperatures; on raising the temperature SO_2 and H_2S are generally evolved and S is often separated. Some metals, such as Sb, Bi, Cu, Hg, react only with warm fairly conc. H_2SO_4, giving off SO_2, and often also H_2S. Au, Ir, Pt, Rh, and W do not interact with H_2SO_4. Regarding the conditions of the interaction of H_2SO_4Aq with metals—concentration, temperature, and products—*v.* Ditte (*A. Ch.* [6] 19, 68). Pattison Muir a. Adie (*C. J.* 53, 47) found that the only products of the interaction of *approximately pure zinc* and dilute H_2SO_4Aq (c. $H_2SO_4.12H_2O$ to c. $H_2SO_4.15H_2O$) were $ZnSO_4Aq$ and H; that with conc. acid (c. $H_2SO_4.H_2O$ to c. H_2SO_4) SO_2 was the chief gaseous product, and that H_2S was also produced at higher temperatures; and that with acid of intermediate concentration (c. $H_2SO_4.2H_2O$) both SO_2 and H_2S were formed in considerable quantities at c. 160°. For experiments on the rate of action of H_2SO_4Aq on different specimens of zinc *v.* Divers a. Shimidzu (*C. J.* 47, 598), who have also examined the production of NH_2OH by the interaction of zinc with H_2SO_4Aq and HNO_3Aq together (*cf.* HYDROXYLAMINE, vol. ii. p. 734). For qualitative experiments on the interaction of H_2SO_4 and *tin*, *v.* Pattison Muir a. Robbs (*C. N.* 45, 69, where references to other memoirs are given). Pullinger (*C. J.* 59, 815) found that *pure zinc* was not acted on by H_2SO_4Aq (1 part conc. acid + 3 parts water by weight) provided the acid had been boiled for a long time before use and the surface of the zinc was quite smooth; if the surface was rough some of the zinc was dissolved. P. also found that oxidisers increased the rate of solution of zinc, and reducers, if not containing S, almost stopped the solution. P. concluded that when the surface of the zinc was rough S_2O_7 was probably formed, and then the action proceeded. Weeren (*B.* 24, 1785) noticed that there was scarcely any reaction between pure zinc and H_2SO_4Aq (c. 20 parts water); he supposed that a layer of H was condensed on the surface of the metal. W. thought that with impure zinc the H is given off from the surface of the more negative metal present, and so the surface of the zinc is left exposed to the action of the acid. W. found that the evolution of H proceeded more rapidly *in vacuo*, and that it was hastened by brushing the surface of the metal. The weight of pure zinc dissolved in 30 mins. was 2·1 mgm. at 0°, 9·3 mgm. at 98°, and 122·1 mgm. at the b.p. of the acid used. W. obtained similar results with Al, Cd, Co, and Fe. *Sodium amalgam* or *zinc amalgam*, with conc. H_2SO_4, gives off H, then quantities of H_2S, then SO_2 and S, and finally only SO_2 (Walz, *C. N.* 23, 245). The interaction of H_2SO_4 and *copper* has been fully examined by Pickering (*C. J.* [2] 18, 112; *cf.* COPPER, vol. ii. p. 253).—8. H_2SO_4 reacts with the *oxides of nitrogen* (not with N_2O) to form $NO_2(SO_2.OH)$ (*v.* NITROSULPHONIC ACID, p. 601).—9. *Phosphoretted hydrogen* reacts slowly with H_2SO_4 at the ordinary temperature, giving SO_2, S, and H_3PO_4 (Rose, *P.* 24, 139).—10. With *sulphuretted hydrogen*, H_2O, S, and SO_2 are formed.—11. *Phosphorus pentoxide* withdraws H_2O from hot conc. H_2SO_4, producing $P_2O_5.H_2O$ and SO_3 (Barreswil, *C. R.* 25, 30; Evans, *Ph.* 8, 127); *phosphorus pentachloride* or *trichloride* forms SO_3 and $POCl_3$, also SO_2Cl_2 when PCl_5 is used (Williamson, *P. M.* [4] 7, 365; Schiff, *A.* 202, 111; *cf.* Michaelis, *J. Z.* 6, 233, 292), and also $Cl(SO_2.OH)$ (Müller, *B.* 6, 277; Geuther, *B.* 5, 925; Thorpe, *C. J.* 37, 358).—12. H_2SO_4 reacts with most *salts* to form sulphates, and set free the acid of the salt if that acid is more volatile than H_2SO_4. In several cases secondary reactions occur between the acid set free and the H_2SO_4; thus, with bromides and iodides, Br and I, and SO_2 or H_2S, are produced. The interaction of H_2SO_4Aq and KBr has been examined by Addyman (*C. J.* 61, 94), who found that the percentage of HBr decomposed varied almost directly with the quantity of H_2SO_4 used, and that when so much H_2SO_4 was present that the water produced in the reaction $2HBr + H_2SO_4 = 2H_2O + SO_2 + Br_2$ caused no sensible dilution of the H_2SO_4, all the HBr was decomposed; with dilute acid, c. 30 p.c. H_2SO_4, using excess of acid, scarcely a trace of HBr was decomposed (*cf.* Feit a. Kubierschki, *J. Ph.* [5] 24, 159). Jackson (*C. J.* 43, 339) finds that the interaction of conc. H_2SO_4 and KI varies according as the acid is present in large excess, or in quantity just sufficient for the KI used. In the first case all the I of the KI is set free along with an equivalent quantity of SO_2; in the second case all the I is liberated with the equivalent quantity of H_2S. Many *salts of acids containing much oxygen, e.g.* dichromates and permanganates, are decomposed by hot conc. H_2SO_4 with evolution of O. The reaction of H_2SO_4Aq with $KMnO_4Aq$ has been examined by Gooch a. Danner (*Am. S.* [3] 44, 301), who found that the quantity of O given off increased with (1) concentration of H_2SO_4Aq, (2) time, (3) temperature; no O was given off after a few hours with 20 p.c. acid at the ordinary temperature, but a considerable quantity of O was produced after five days' action, and c. the same result was obtained by heating to 80° for one and a half hours (*cf.* Jones, *C. J.* 33, 95).—13. Conc. H_2SO_4 reacts with many oxygenated *organic compounds*, withdrawing H_2O; with benzenoid hydrocarbons it forms sulpho- acids; many organic compounds, such as sugar, starch, &c., are charred by warm H_2SO_4.—14. Pictet (*C. R.* 115, 708, 814) has examined the *reactions of sulphuric acid at low temperatures*, using acid of 89 p.c. H_2SO_4; no action occurred below −125° with such bodies as NaOH, NaCl, NH_3, Na_2CO_3, Na, K; in most cases action began suddenly at temperatures varying from −120° to −60°.—15. H_2SO_4 combines with *water*; the hydrates $H_2SO_4.H_2O$, $H_2SO_4.2H_2O$, and $H_2SO_4.3H_2O$ have been isolated as solids (*v. infra*).—16. Conc. H_2SO_4 combines with *sulphur trioxide* to form $H_2SO_4.SO_3$ and other compounds (*v.* PYROSULPHURIC ACID).

For the reactions of fuming H_2SO_4 *v.* PYROSULPHURIC ACID (p. 625). The salts of H_2SO_4 are described under SULPHATES (p. 567). Both amides of H_2SO_4, viz. $SO_2.OH.NH_2$ and $SO_2(NH_2)_2$, have been isolated (*v.* SULPHAMIC ACID, p. 567, and SULPHAMIDE, p. 567); the imide $SO_2.NH$ is also known, *v.* SULPHIMIDE, p. 587; *cf.* also SULPHIMIDO-AMIDE $NH(SO_2.NH_2)_2$, p. 587, and IMIDOSULPHONIC ACID $NH(SO_2.OH)_2$, p. 600.

Constitution of sulphuric acid.—The reactions of H_2SO_4 with Cl and with PCl_5, and the reactions of the products with water, also the formation of $SO_2.OH.NH_2$, $SO_2(NH_2)_2$, and $SO_2.NH$, show that H_2SO_4 contains two OH groups. The fact that only one compound, $SO_2.OEt.OMe$, can be formed from H_2SO_4 shows that the two OH groups in $SO_2(OH)_2$ are related to the rest of the molecule in the same way; hence the formula for the acid is to be written $S{<}\begin{smallmatrix}O.OH\\O.OH\end{smallmatrix}$ or $O_2S{<}\begin{smallmatrix}OH\\OH\end{smallmatrix}$. Inasmuch as SO_2Cl_2 is formed from $SO_2(OH)_2$ by the reaction of PCl_5, as certain hydrocarbons interact with SO_2Cl_2 to form SO_2R_2 (where R = Me, Ph, &c.), and as these compounds SO_2R_2 are reduced to SR_2, where the radicles R are certainly in direct union with S, it is extremely probable that the OH groups in $SO_2(OH)_2$ are in direct union with S, and hence the formula $O_2S{<}\begin{smallmatrix}OH\\OH\end{smallmatrix}$ is to be preferred to $S{<}\begin{smallmatrix}O.OH\\O.OH\end{smallmatrix}$ for sulphuric acid. It is

undecided whether the group SO_2 in $O_2S.OH.OH$ has the constitution O.S.O or  **.**

Hydrates of sulphuric acid. Two solid hydrates have been isolated; a liquid hydrate has probably also been isolated.

Monohydrate $H_2SO_4.H_2O$ (*Tetrahydroxysulphuric acid* $SO(OH)_4$). Large, colourless, six-sided tablets; formed by mixing 1 part conc. H_2SO_4 with rather less than one-fifth part water (by weight), and surrounding with a freezing mixture. The crystals melt at 7·5° (Pierre a. Puchot, *A. Ch.* [5] 2, 164). The hydrate readily remains liquid considerably below its m.p. S.G. $\frac{0^\circ}{4^\circ}=1{\cdot}7943$ (for the liquid) (Mendeléeff, *B.* 19, 380); 1·77806 at 15°, 1·77423 at 20°, 1·77071 at 25° (Perkin, *C. J.* 49, 777; determinations made with liquid, and referred to water at same temperatures). Thomsen gives H.F. from liquid H_2SO_4 and H_2O $[H^2SO^4,H^2O]=6,379$ (*Th.* 3, 54); Berthelot gives 6,120 (*C. R.* 78, 716). Heat of fusion = 3680 g. units (for 116 g.) $H_2SO_4.H_2O$ (Berthelot, *C. R.* 78, 716). For vapour pressures from 143° to 204° *v.* Tate (*P. M.* [4] 26. 502).

Dihydrate $H_2SO_4.2H_2O$ (*Perhydroxysulphuric acid* $S(OH)_6$). Formed by adding ·368 parts H_2O to 1 part pure H_2SO_4, by weight. This hydrate has not been obtained as a solid; the S.G. of the liquid at $\frac{0^\circ}{4^\circ}$ is given by Mendeléeff (*B.* 19, 380) as 1·6655 (*cf.* Perkin, *C. J.* 49, 777).

It is stated (*v.* Mendeléeff, *B.* 19, 388) that the maximum contraction when H_2SO_4 and H_2O are mixed occurs when the compounds are present in the ratio $H_2SO_4{:}2H_2O$, but Pickering (*C. J.* 57, 84) says that the maximum does not correspond with the composition of any hydrate the existence of which is indicated in other ways.

Tetrahydrate $H_2SO_4.4H_2O$. Obtained by Pickering (*C. J.* 57, 339) as a crystalline solid, melting at −25°, by cooling H_2SO_4Aq containing 57·6 p.c. H_2SO_4 ($H_2SO_4.2H_2O$ corresponds with 57·66 p.c. H_2SO_4). The crystals are large and well defined, and resemble $H_2SO_4.H_2O$; the compound may be kept liquid at 20° to 25° below its freezing point.

Hydrates of sulphuric acid in aqueous solution.—According to Mendeléeff (*B.* 19, 380; *cf.* his *Principles of Chemistry*, vol. ii. p. 234), an examination of the connections between the concentration of H_2SO_4Aq and the S.G. indicates the existence of hydrates that have not yet been isolated. Pickering (*C. J.* 57, 64) comes to the same general conclusion from an extended examination of the connections between the changes of composition of H_2SO_4Aq and the changes of S.G., heat capacity, electrical conductivity, heat of solution, and expansion by heat of the solution. Pickering's reasoning is a special case of that explained in the article Solutions (part ii. p. 492); for the detailed argument, and criticisms of it, *v.* Pickering, *C. J.* 57, 64; Rücker, *P. M.* [5] 32, 304; 33, 204; P., *P. M.* [5] 33, 132, 463; *cf.* Mendeléeff, *Z. P. C.* 1, 275; and Crompton, *C. J.* 53, 116.

PERSULPHURIC ACID $H_2S_2O_8Aq$. This acid is present in the solution obtained by electrolysing H_2SO_4Aq of certain concentrations; Berthelot (*C. R.* 90, 269; 112, 1481) obtained a quantity of the acid equal to from 88 to 123 g. S_2O_7 per litre by electrolysing H_2SO_4Aq containing water and acid in the ratio $10H_2O{:}H_2SO_4$ (*cf.* Sulphuric peroxide, p. 616; and Sulphuric acid, *Reactions*, No. 2, p. 623). According to Traube (*B.* 22, 1518, 1528) a solution of $H_2S_2O_8$ in H_2SO_4 does not oxidise $H_2C_2O_4$, HNO_2, CO, or $Cr_2(SO_4)_3$; Richarz, however (*B.* 21, 1670), says that oxalic and nitrous acids are oxidised. The acid has not been isolated; by electrolysing at temperatures below 0°, and then adding BaOAq or KOHAq, the Ba or K salt is obtained. The formula $H_2S_2O_8$ is given rather than HSO_4, because of the results of Bredig's measurements of the conductivities of solutions of the K salt. For salts of this acid *v.* Persulphates, p. 582.

PYROSULPHURIC ACID $H_2S_2O_7$ (*Disulphuric acid*). A solution of this acid in H_2SO_4 is known as *fuming sulphuric acid*, or *Nordhausen acid*. This acid is obtained by adding rather more SO_3 to H_2SO_4 than the proportion $SO_3{:}H_2SO_4$, cooling, and spreading out the crystals that form over nearly conc. H_2SO_4 under a bell-jar till the excess of SO_3 is removed (Schultz-Sellack, *B.* 4, 109). Forms large crystals, melting at 35°. Easily decomposed by heat to H_2SO_4 and SO_3. $H_2S_2O_7$ is dibasic, forming salts MHS_2O_7 and $M_2S_2O_7$ (*v.* Pyrosulphates, p. 583). *Fuming sulphuric acid* is a solution of $H_2S_2O_7$ in H_2SO_4; it is prepared by heating dry $FeSO_4$ in fireclay vessels and collecting the oily, fuming liquid that distils over. The acid fumes strongly in the air, and gives off SO_3 when warmed. But few of the reactions described for *pyrosulphuric acid*, or for *fuming sulphuric acid*, can be set down as belonging to a definite compound, but rather to solutions of $H_2S_2O_7$ (and perhaps other compounds of H_2SO_4 and SO_3) in H_2SO_4. Finely-divided *silver* dissolves easily; the solution poured into water gives Ag_2SO_4 and SO_2; *mercury* reacts similarly; spongy *copper* has a slight reaction, giving Cu_2S and $CuSO_4$ (Divers a. Shimidzu, *C. J.* 47, 636). Distilled with *phosphorus pentoxide in a stream of hydrogen chloride*, $Cl(SO_2.OH)$ is formed; the same acid is formed by heating with PCl_5, and also by heating 'crystallised fuming sulphuric acid' with HCl (*v.* Chlorosulphonic acid, p. 509). *Nitrogen dioxide* passed into well-cooled pyrosulphuric acid gives $NO_2(SO_2.OH)$ (*v.* Nitrosulphonic acid, p. 601). By saturating ordinary conc. H_2SO_4 with SO_3 (Jacquelain, *A. Ch.* [3] 30, 343), or by cooling fuming H_2SO_4 to −10° (Wackenroder, *Ar. Ph.* [2] 87, 267), the compound $H_2S_2O_7.2H_2SO_4$ ($=3H_2SO_4.SO_3$) is said to be obtained in transparent crystals. Schultz-Sellack (*B.* 4, 109) failed to obtain any compound of H_2SO_4 and SO_3, except $H_2S_2O_7$. Crystals of the composition $H_2SO_4.3SO_3$ ($=H_2S_4O_{13}$) melting at 8°–10° are said by Weber (*P.* 159, 313) to be formed by adding cooled conc. H_2SO_4, little by little, to SO_3.

SULPHUROSAMIC ACID $SO.OH.NH_2$ *v.* Thionamic acid, p. 695.

SULPHUROUS ACID and HYPOSULPHUROUS ACID.

SULPHUROUS ACID H_2SO_3Aq. The acid has not been isolated; a solution of SO_2 in water reacts as a weak dibasic acid, forming salts of the types M^IHSO_3, $M^I_2SO_3$, and $M^{II}SO_3$ (*v.* Sulphites, p. 587). H.F. $[H^2,S,O^3,Aq] = 147,130$; $[H^2O,S,O^2,Aq] = 78,780$ (from rhombic S; *Th.* 2, 251).

The methods of formation and preparation of H_2SO_3Aq are sufficiently detailed under Sulphur dioxide (p. 613); it is only necessary to add water to the SO_2 obtained.

Properties.—An aqueous solution of H_2SO_3 readily decomposes, giving off SO_2; on standing for some time in the air, and more quickly by warming, H_2SO_4Aq is formed with production of much heat; $[H^2SO^3Aq,O] = 63,634$ (*Th.* 2, 253). H_2SO_3Aq is altered by the action of light, so that after exposure to light for some time the solution ppts. Ag_2S from $AgNO_3Aq$, and reduces silver haloid compounds, forming some Ag_2S; the solution after exposure to light behaves like a dilute solution of a polythionic acid (Stas, *Chem. Proport.* 64). Löw (*L'Institut*, 1873. 67) says that dilute H_2SO_3Aq is changed to H_2SO_4Aq and S by long exposure to light.

Reactions.—1. *Heated in a closed tube* to 170°–180°, H_2SO_4Aq and S are formed, and after a time also H_2S (Geitner, *A.* 129, 350).—2. Decomposed by an *electric current*, giving H_2SO_4Aq at the positive pole and S at the negative; with a weak current $H_2S_2O_4Aq$ is probably formed at first at the negative pole (Guéroult, *C. R.* 85, 225).—3. *Phosphorus pentachloride* produces $SOCl_2$ and $POCl_3$ (Kremers, *A.* 70, 297; Schiff, *A.* 102, 111).—4. *Sulphurous chloride* with H_2SO_3Aq produces polythionic acids (*v.* Debus, *C. J.* 53, 345).—5. Vapour obtained by heating H_2SO_3Aq reacts with *chlorine*, when passed over red-hot Pt, to form $Cl(SO_2.OH)$ (*v.* Chlorosulphonic acid, p. 599).—6. $NO_2(SO_2.OH)$ (*v.* Nitrosulphonic acid, p. 601) is formed by the interaction of moist SO_2, *i.e.* H_2SO_3Aq, with *nitric oxide* or *nitrogen dioxide.*—7. H_2SO_3Aq is oxidised to H_2SO_4Aq by *oxygen*, the *halogens*, and many other *oxidisers.*—8. Heated with *phosphorus* in a closed tube to 200°, H_2S is produced (Oppenheim, *Bl.* [2] 1, 163).—9. Reduced by *zinc* and *dilute sulphuric acid* to H_2S (*v.* Reinsch, *D. P. J.* 163, 286; 181, 332); with *zinc* alone, H_2SO_3Aq is partly reduced, probably giving $H_2S_2O_4Aq$ (*v.* Hyposulphurous acid, p. 627).—10. Many *metals* which evolve H from H_2SO_4Aq or HClAq react with H_2SO_3Aq to form sulphites and sulphides, with evolution of little or no H (*v.* Federoff, *Chem. Zeitung*, 5, 15). For a fairly full qualitative examination of the interaction of Al, Cd, Mg, Ni, and Zn with H_2SO_3Aq, *v.* Schweitzer (*C. N.* 23, 293).—11. Many of the *oxyacids of the halogens* are reduced to hydracids by H_2SO_3Aq.—12. *Phosphorous acid* gives H_3PO_4Aq and H_2S; then S, and thionic acids (Wöhler, *A.* 39, 252; Maquenne, *Chem. Zeitung.* 1890 [1] 511).—13. *Phosphoretted hydrogen* produces H_3PO_4Aq, and S (Cavazzi, *G.* 16, 169). 14. *Hydrogen sulphide* passed into H_2SO_3Aq forms a solution containing H_2SO_4, $H_2S_3O_6$, $H_2S_4O_6$, $H_2S_5O_6$, probably $H_2S_6O_6$, S in suspension, and a colloidal form of S in solution; if the passage of H_2S is continued until reaction ceases the final products are S and H_2O (Debus, *C. J.* 53, 282; *cf.* Thionic acids, p. 698).—15. Many *metallic salts* are reduced, in aqueous solutions, by H_2SO_3Aq; salts of Ag and Hg to the metals, ferric to ferrous salts, &c. According to Divers a. Shimidzu (*C. J.* 49, 575), the reduction does not consist in the withdrawal of O by H_2SO_3Aq and the oxidation of that acid thereby to H_2SO_4Aq. The first step is looked on by D. a. S. as probably the formation of a sulphite of the metal of the salt, and this is followed by either the decomposition of this sulphite by water to metal and H_2SO_4Aq, or the reaction of the sulphite with some of the original, unchanged, salt to form metal and a persulphite (or -ic sulphite) of the metal.—16. With *potassium thiosulphate* H_2SO_3Aq forms K tri- tetra- and penta-thionates, and S (Debus, *C. J.* 53, 343).—17. H_2SO_3Aq dissolves many freshly ppd. *metallic sulphides*, *e.g.* MnS, FeS, ZnS, forming thiosulphates (Schönbein, *P.* 104, 300; Heldt, *J. pr.* 83, 20).—18. *Alkali nitrites* give salts of nitrilosulphonic acid $N(SO_2.OH)_3$ (*q. v.*, p. 601), and also salts of oxy-imidosulphonic acid $N(OH)(SO_2.OH)_2$ (*q. v.*, p. 602). Using a dilute, ice-cold solution of H_2SO_3 (= 5 p.c. SO_2), and adding 40 g. KNO_2 in 1,000 c.c. water to 3 litres of this H_2SO_3Aq, Raschig (*A.* 241, 234) obtained $NH_2(SO_2.OK)$ (*cf.* Sulphamic acid, p. 567). Under certain conditions of concentration and temperature NO and N_2O, also NH_3 and sometimes NH_2OH, are produced. With *nitrous acid* the final products are NH_3, NO, N_2O, and H_2SO_4Aq; according to Raschig (*l.c.*), $NH_2(SO_2.OH)$ is always formed, and the gaseous products are to be looked on as resulting from secondary reactions between nitrous acid and $NH_2(SO_2.OH)$ or other nitrogenised sulphonic acids formed in the primary reaction between the nitrous and sulphurous acids. With *silver* and *mercurous nitrites* Divers a. Haga (*C. J.* 51, 659) found that sulphites were produced, along with some NO and H_2SO_4, and more or less NH_2OH.—19. For the reaction of H_2SO_3Aq with *potassium platinochloride* *v.* Platino-sulphonates, this vol., p. 285.

Neither the amide $SO(NH_2)_2$ (*v.* the heading Thionamide), nor the imide SO.NH, of H_2SO_3 has been isolated; and it is doubtful whether the acid $SO.OH.NH_2$ or $SO_2.NH_2.H$ is known. *v.* Thionamic acid.

Constitution of sulphurous acid. The fact that many haloid derivatives of hydrocarbons interact with $NaHSO_3$ to form sulphonic acids—*e.g.* $EtI + NaHSO_3 = EtSO_3H + NaI$—makes it probable that the Na in $NaHSO_3$ is in direct union with the S, because the S in sulphonic acids is almost certainly in direct union with the hydrocarbon radicle; hence it is likely that one H atom in H_2SO_3 is directly combined with the S atom, and hence the formula for H_2SO_3 is probably $H.SO_2.OH$. This view of the constitution of H_2SO_3 is insisted on, and illustrated, by Divers (*C. J.* 47, 205).

Hydrates of sulphurous acid. Colourless, ice-like crystals are obtained by passing SO_2 into water surrounded by ice, by cooling saturated SO_2Aq, or by passing moist SO_2 through a tube kept at a low temperature. After filtering quickly in a covered filter, and pressing between filter paper at 8°, the crystals have the composition $H_2SO_3.xH_2O$; Dopping (*Petersburg Acad. Bull.*, 7, 100) found $x = 10$, Pierre (*A. Ch.* [3] 23, 416) found $x = 8$, Schönfeld (*A.* 95, 22) found $x = 14$, Roozeboom (*R. T. C.* 3, 29, 59, 75, 84; 4, 65) found $x = 6$, and this was confirmed by Geuther (*A.* 224, 218). Roozeboom (*l.c.*) gives S.G. of the crystals as 1·21 (referred to water at 4°); Geuther (*l.c.*) gives 1·147 as the S.G. after melting at 14°, and 14° as the m.p. with separation of some liquid SO_2 under the layer of SO_2Aq. R. (*l.c.*) gives the following dissociation-pressures, which are independent of the quantity of the hydrate: 303 mm. at 0°, 754 mm. at 7·05°, 1177 mm. at 10°, 1773 mm. at 12·1°. According to R. the critical temperature of decomposition is 7·1° in an open vessel and 12·1° in a closed vessel.

HYPOSULPHUROUS ACID $H_2S_2O_4Aq$. This acid has not been isolated. An aqueous solution is probably formed by decomposing the Na salt by dilute H_2SO_4Aq or $H_2C_2O_4Aq$, and also perhaps by digesting H_2SO_3Aq with zinc clippings till the liquid is brownish red; but neither the aqueous solution of the acid, nor any of its salts, has been obtained free from impurities. For preparation of the sodium salt, and for references, *v.* HYPOSULPHITES (p. 592).

SULPHUVINURIC ACID $C_4H_4N_2SO_2$, *i.e.* $\begin{matrix}S-C(NH_2)\\CH:C(CO_2H)\end{matrix}\!>\!N$ (Strende, *A.* 261, 26). Formed from di-bromo-pyruvic acid and a conc. solution of thio-urea (Nencki a. Sieber, *J. pr.* [2] 25, 74). Crystals (containing 2aq), sl. sol. cold water. Reduces Fehling's solution in the cold. $FeCl_3$ gives a deep violet colour.—**Salts:** MgA'_2.—ZnA'_2: minute needles.—$HA'HCl$.—$HA'HBr$.—$HA'HNO_3aq$: needles, sl. sol. water.

SULPHYDRO-ACETIC ACID *v.* THIOGLYCOLLIC ACID.

SULPHYDRO-ACETONE $CH_3.CO.CH_2.SH$.

Ethyl derivative $EtS.CH_2Ac$. (171°). Formed from chloro-acetone and NaSEt (Autenrieth, *B.* 24, 165). Yields a phenyl hydrazide [57°].

Phenyl derivative $PhS.CH_2Ac$. [36°]. (266°). Formed from $CH_3.CO.CH_2Cl$ and NaSPh in alcohol in the cold. Crystals. Yields a phenyl-hydrazide [87°] (A., *cf.* Delisle, *A.* 260, 250). Combines with $KHSO_3$ and $NaHSO_3$.

SULPHYDRO-ACETOPHENONE. *Phenyl derivative* $C_{14}H_{12}SO$, *i.e.* $C_6H_5.S.CH_2.CO.C_6H_5$. [53°]. Formed from ω-bromo-acetophenone and NaOPh (Delisle, *B.* 22, 309). Needles (from alcohol), v. sol. ether and acetone.

SULPHYDRO-ACETYL-PROPIONIC ETHER. *Phenyl derivative* $C_{13}H_{16}SO_3$, *i.e.* $C_6H_5.S.CH_2.CO.CH_2.CH_2.CO_2Et$. (197° at 15 mm.). Formed from bromo-acetyl-propionic ether and NaSPh (Delisle, *B.* 22, 309).

SULPHYDRO-ALLYL-QUINAZOLINE. *Dihydride* $C_6H_4\!<\!\begin{matrix}CH_2.N.C_3H_5\\NH.CS\end{matrix}$. [91°]. Formed from ω-oxy-tolyl-allyl-thio-urea and HClAq at 100° (Söderbaum a. Widman, *B.* 22, 1670). Needles, v. e. sol. alcohol and benzene.

Reference. — OXY-SULPHYDRO-ALLYL-QUINAZOLINE.

DISULPHYDRO-DI-ALLYL-TRIAZOLE $NH\!<\!\begin{matrix}CS.N.C_3H_5\\CS.N.C_3H_5\end{matrix}$. Formed from allyl-thio-urea and HNO_2 (Hector, *J. pr.* [2] 44, 505). Oil.—$B'_2H_2PtCl_6$: crystalline pp.

o-**SULPHYDRO-BENZOIC ACID** $C_6H_4(SH).CO_2H$. *Thio-salicylic acid.* Formed by reducing *o*-sulpho-benzoic chloride with zinc-dust and H_2SO_4 (Delisle, *B.* 22, 2206). Amorphous powder, sl. sol. hot water, v. sol. alcohol. Not volatile with steam.—AgA'.

Thio-amide $C_6H_4(SH).CS.NH_2$. Formed by heating *o*-oxy-benzamide with P_2S_5 (Spilker, *B.* 22, 2771). Minute dark-red crystals.

Phenyl derivative $C_6H_5S.C_6H_4.CO_2H$. [166°]. Formed from *o*-diazobenzoic acid, phenyl mercaptan, and NaOHAq at 50° (Graebe a. Schultess, *A.* 263, 4). Plates (from alcohol) or needles (from HOAc); sl. sol. water.—NH_4A'.—KA': needles, v. sol. water.—EtA'. [151°].

m-Sulphydro-benzoic acid $C_6H_4(SH).CO_2H$. [147°]. Formed by the action of tin and HClAq on $C_6H_4(SO_2Cl).COCl$ (Frerichs, *B.* 7, 793). Colourless plates, m. sol. water.—$BaA'_2\,2\frac{1}{2}aq$.—HgA'_2.—$PbC_7H_4SO_2\,3aq$.—$Cu(OH)A'$.—AgA'.

α-**SULPHYDRO-BUTYRIC ACID** $CHEt(SH).CO_2H$. Formed from α-bromo-butyric acid and alcoholic KSH (Duvillier, *Bl.* [2] 30, 507). Sol. water, alcohol, and ether.

Sulphydro-isobutyric acid $HS.CMe_2.CO_2H$. Formed from α-bromo-isobutyric ether by successive treatment with alcoholic K_2S and alcoholic KOH (Lovén, *J. pr.* [2] 33, 109). Oil.

α-**SULPHYDRO-CINNAMIC ACID** $C_6H_5.CH:C(SH).CO_2H$. [119°]. Formed, together with sulphocyanic acid, by heating benzylidene-rhodanic acid $C_6H_5:CH:C(SH).CO.S.CN$ with baryta-water (Ginsburg a. Bondzynski, *B.* 19, 128; *M.* 8, 350). Yellowish crystals. V. sol.

alcohol, ether, benzene, and CS_2, nearly insol. water. By treatment with iodine in alcoholic solution it is oxidised to di-sulphido-di-cinnamic acid $S_2(C_2HPh.CO_2H)_2$.

Reference.—NITRO-SULPHYDRO-CINNAMIC ACID.

β-SULPHYDRO-CROTONIC ACID. *Ethyl derivative* $CH_3.C(SEt){:}CH.CO_2H$. [113°]. Formed from β-chloro-crotonic acid [94·5°], mercaptan, and Na (Autenrieth, *A.* 254, 235; *B.* 20, 3189). Crystals, insol. water, v. sol. ether and alcohol. Gives a dark-green colour on warming with isatin and H_2SO_4. Yields $CH_3.C(SEt){:}CH_2$ (110°) on heating above its melting-point.—BaA'_2 aq.—AgA′: silky needles, not decomposed by hot water. Ac_2O forms the compound $CH_3.C(SEt){:}CH.CO.OAc$, a brownish oil.

Isomeride of the ethyl derivative $CH_3.C(SEt){:}CH.CO_2H$. [92°]. S. (alcohol) 20. Formed in like manner from the isomeric β-chloro-crotonic acid (A.). Crystals, nearly insol. water. Forms a dark-green liquid on warming with isatin and H_2SO_4. When heated alone it yields the same ethyl-sulphydro-propylene (110°) as its isomeride.—BaA'_2 aq: thin plates (from Aq).

Phenyl derivative v. PHENYL-SULPHYDRO-CROTONIC ACID.

SULPHYDRO-ETHYL ALCOHOL $HO.C_2H_4.SH$. Formed from glycolic chlorhydrin and alcoholic KSH (Carius, *A.* 124, 258). Oil, v. e. sol. alcohol. Oxidised by HNO_3 to isethionic acid.—$Hg(C_2H_5OS)_2$. Needles (from warm alcohol).

SULPHYDRO - ETHYL - QUINAZOLINE. *Dihydride* $C_6H_4<\substack{CH_2.NEt\\NH.CS}$. [103°]. Formed by warming ω-tolyl-ethyl-thio-urea with HCl (Söderbaum a. Widman, *B.* 22, 2936). Needles. —$B'HAuCl_4$. [118°].—$B'_2H_2PtCl_6$. [208°].

SULPHYDRO - METHANE DISULPHONIC ACID $HS.CH(SO_3H)_2$. Formed by boiling the tri-sulphonic acid with HOAc (Albrecht, *A.* 161, 134). Gives a blue colour with $FeCl_3$.—$K_2A''\frac{1}{2}$aq. —$Pb_3(CHS_2O_6)_2$ 8aq. Small needles.

Sulphydro-methane trisulphonic acid $HS.C(SO_3H)_3$. Formed by boiling CS_2 or $CSCl_2$ with K_2SO_3Aq.—K_3A''' 2aq: triclinic crystals. S. 2 at 12°. Gives a blue colour with $FeCl_3$.—$(NH_4)_3A'''$ aq. Thin plates.

SULPHYDRO-METHENYL-AMIDO-CRESOL $\left[4\ \substack{1\\2}\right]$ $C_6H_3Me<\substack{O\\N}>C.SH$. [217°]. Formed by heating benzene-azo-*p*-cresol with CS_2 at 200° (Jacobsen a. Schenke, *B.* 22, 3235). Needles.

SULPHYDRO - METHENYL - AMIDO - (α) - NAPHTHOL $C_{10}H_6<\substack{N\\O}>C.SH$. [above 220°]. Formed by heating an alcoholic solution of $S_2(C_{10}H_6.NH_2[1{:}2])_2$ with CS_2 (Jacobson, *B.* 21, 2624). Needles. Oxidised by K_3FeCy_6 to a crystalline disulphide.

Sulphydro - methenyl - amido - (β) - naphthol. [249°]. Formed by heating benzene-azo-(β)-naphthol with CS_2 at 250° (Jacobson, *B.* 21, 414). Needles, sl. sol. benzene. HClAq at 170° yields amido-(β)-naphthol. An alcoholic solution of iodine forms crystalline $(C_{10}H_6<\substack{N\\O}>C)_2S_2$.

SULPHYDRO - METHENYL - α - AMIDO-NAPHTHYL MERCAPTAN $C_{10}H_6<\substack{N\\S}>C.SH$. [above 240°]. Formed by heating α-naphthyl thiocarbimide with S at 225°, and got also by the action of CS_2 on di-amido-di-naphthyl di-sulphide (Jacobson, *B.* 21, 2625; 24, 1406). Minute rosettes, sol. alcohol. Oxidised by K_3FeCy_6 to $(C_{10}H_6<\substack{N\\S}>C)_2S_2$.—$B'HgCl_2$. [210°].

Sulphydro - methenyl - amido - (β) - naphthyl mercaptan [232°]. Formed by heating (β)-naphthyl thiocarbimide with S. Minute needles. Yields a methyl ether [74°], crystallising in needles.

SULPHYDRO - METHENYL - *o* - AMIDO-PHENOL $C_6H_4<\substack{N\\O}>C.SH$. *Thiocarbamido-phenol.* [196°]. Formed by boiling an alcoholic solution of *o*-amido-phenol for several days with CS_2 in a current of H as long as H_2S is given off (Dünner, *B.* 9, 465). Formed also by heating oxy-phenyl-thio-urea, and by heating *o*-oxy-phenyl-allyl-thio-urea with HCl at 130° (Von Chelmicki, *J. pr.* [2] 42, 442; *B.* 20, 177). Obtained also by adding dilute alcohol to a mixture of potassium xanthogenate and amido-phenol hydrochloride (Kalckhoff, *B*, 16, 1825). Needles (from water), sl. sol. cold water. Sol. NH_3Aq, crystallising therefrom unaltered.

Reactions.—1. Converted in *o*-amido-phenol by HClAq at 170°, and by NH_3Aq at 200°.—2. Ac_2O yields $C_6H_4<\substack{N\\O}>C.SAc$ [120°].—3. BzCl forms benzenyl - amido - phenol and $C_6H_4(NHBz).OBz$.—4. An alcoholic solution of iodine, added to its solution in NaOHAq, forms $(C_6H_4<\substack{N\\O}>C)_2S_2$ [110°], which is re-converted by hot dilute NaOHAq into sulphydro-methenyl-amido-phenol. — 5. Boiling methyl-aniline forms a base (? $C_6H_4<\substack{N\\O}>C.NPhMe$) which yields $B'_2H_2PtCl_6$.

Salt.—AgC_7H_4NSO. Amorphous.

Ethyl ether EtC_7H_4NSO. (c. 267°). Solid, melting below 35°; volatile with steam.

SULPHYDRO-METHENYL-AMIDO-PHENYL-MERCAPTAN $C_6H_4<\substack{N\\S}>C.SH$. [179°] (H.); [174°] (J. a. F.).

Formation.—1. By digesting *o*-amido-phenol with CS_2 (Hofmann, *B.* 20, 1789).—2. By heating $C_6H_5.N_2.C_6H_5$ with CS_2 at 265° (Jacobson a. Frankenbacher, *B.* 24, 1403).—3. By heating phenyl thiocarbimide with sulphur.

Properties.—Needles or plates, v. sol. alcohol and ether. Forms $B'HgCl_2$. Oxidised by $K_2Cr_2O_7$ to $(C_6H_4<\substack{N\\S}>C)_2S_2$, which yields $B'K_2Cr_2O_7$ [180°]. MeI yields $C_6H_4<\substack{N\\S}>C.SMe$ [52°], which forms $B'_2H_2PtCl_6$, crystallising in plates.

SULPHYDRO - METHENYL - BENZENYL - THIO-AMIDOXIM $C_6H_5.C<\substack{N.S\\N}>C.SH$. [162°]. Formed by the action of CS_2 on an alkaline alcoholic solution of benzenyl-amidoxim (Crayen, *B.* 24, 388). Needles, nearly insol. water and cold alcohol. Conc. HClAq at 150° decomposes it into benzoic acid, CO_2, NH_3, H_2S, and S. NaOEt and EtI yield $C_6H_5.C<\substack{N.S\\N}>CEt$ [49°].

while benzyl chloride forms, in like manner, $C_4H_3.C<\begin{matrix}N.S\\N\end{matrix}>C.CH_2Ph$ [79°].

SULPHYDRO - METHENYL - *p* - TOLYL - METHENYL-THIO-AMIDOXIM $C_9H_8N_2S_2$ *i.e.* $C_6H_4Me.C<\begin{matrix}N.S\\N\end{matrix}>C.SH$. [166°]. Formed from CS_2 and tolyl-methenyl-amidoxim (Crayen, *B.* 24, 391). Crystals (from alcohol acidulated with HOAc), insol. water, sl. sol. ether. Forms salts with bases. *p*-Tolyl-methenyl-amidine forms the salt $C_6H_4Me.C(NH_2):NHHA'$ [172°]. Boiling EtI and NaOEt yield $C_6H_4Me.C<\begin{matrix}N.S\\N\end{matrix}>C.SEt$ [37°].

SULPHYDRO - METHYL - GLYOXALINE $C_4H_6SN_2$ *i.e.* $\begin{matrix}CH.NMe\\CH-N\end{matrix}>C.SH$. [142°]. (c. 280°). Formed by boiling $CH(OEt)_2.CH_2.NH_2$ with methyl thiocarbimide, alcohol, and dilute (30 p.c.) H_2SO_4 (Wohl a. Marckwald, *B.* 22, 1354). Plates, v. sol. water, sol. alcohol.—B'_2PtCl_4.—$B'AuCl_3$.—$C_4H_5AgSN_2$.—B'MeI. [148°]. Needles.

Methyl derivative $\begin{matrix}CH.NMe\\CH-N\end{matrix}>C.SMe$. *Methylimidazolyl methyl sulphide.* (225° uncor.). Formed by treatment with MeI and alkalis. Liquid, miscible with water, alcohol, and ether. Boiling dilute HNO_3 forms $C_5H_7(NO_2)SN_2$ [85°], which yields $B'_2H_2PtCl_6$ [197°]. $C_5H_8SN_2MeI$. [173°]. Needles, v. sol. Aq.

Reference. — OXY-SULPHYDRO-DI-METHYL-GLYOXALINE.

SULPHYDRO-DI-METHYL-PYRIDINE $CS<\begin{matrix}CH:CMe\\CH:CMe\end{matrix}>NH$. [210°-215°]. Formed by heating oxy-di-methyl-pyridine with P_2S_5 at about 160° (Guthzeit a. Epstein, *B.* 20, 2113). Needles, v. sol. hot water and alcohol.

SULPHYDRO - METHYL - QUINAZOLINE. *Dihydride* $C_6H_4<\begin{matrix}CH_2.NMe\\NH.CS\end{matrix}$. [139°]. Formed by warming ω-oxy-tolyl-methyl-thio-urea with HClAq (Söderbaum a. Widman, *B.* 22, 2935). Needles.—$B'_2H_2PtCl_6$. [195°].—$B'HAuCl_4$. [153°]. Minute needles.

SULPHYDRO-METHYL-QUINOLINE $C_{10}H_9NS$ *i.e.* $C_6H_4<\begin{matrix}CMe:CH\\N=C.SH\end{matrix}$. [253°]. Formed by heating (*Py.* 3,1)-oxy-methyl-quinoline with P_2S_5 (Roos, *B.* 21, 625). Small brown needles (from alcohol). Tastes bitter. Insol. cold water. Does not react with hydroxylamine and phenyl-hydrazine. H_2O_2 forms $C_{20}H_{16}N_2S_2$ [167°] crystallising from benzene in plates. EtI and alcohol at 100° form $C_6H_4<\begin{matrix}CMe:CH\\N=C.SEt\end{matrix}$, which is oily and yields B'HI [240°] and $B'_2H_2PtCl_6\frac{1}{2}aq$ crystallising in reddish prisms.

Sulphydro-methyl-quinoline $C_6H_4<\begin{matrix}C(SH):CH\\N=CMe\end{matrix}$. [187°]. Got by heating (*Py.* 1,3)-oxy-methyl-quinoline with P_2S_5 at 150° (Roos, *B.* 21, 629). Yellow prisms (from water). EtI and NaOEt yield $C_{10}H_8EtNS$ [56°].—B'HCl. [205°-210°] (Conrad a. Limpach, *B.* 21, 1972).

SULPHYDRO-METHYL-THIAZOLE. *Dihydride* $\begin{matrix}CHMe.S\\CH_2-N\end{matrix}>C.SH$. [82°]. Formed from β-bromo-propyl-amine hydrobromide, NaOHAq, and CS_2 (Hirsch, *B.* 28, 968). White needles, v. sol. hot water. Yields $C_3H_3MeNS(SMe)$ (217°), $C_3H_3MeNS(SEt)$ (229°), and the propyl ether $C_3H_3MeNS(SC_3H_7)$ (247°).

ψ-SULPHYDRO-(α)-NAPHTHYL-METHYL-BIAZOLE $O<\begin{matrix}CMe:N\\CS-NC_{10}H_7\end{matrix}$. [86°]. Formed from acetyl (α)-naphthyl-hydrazine and $CSCl_2$ in $CHCl_3$ (Preund, *B.* 24, 4184). Yellow needles, v. e. sol. alcohol. The isomeride from (β)-naphthyl-hydrazine melts at 109°.

SULPHYDRO-PENTHIAZOLE. *Dihydride* $CH_2<\begin{matrix}CH_2.S\\CH_2.N\end{matrix}>C.SH$. [132°]. Formed by shaking γ-bromo-ethylamine hydrobromide with NaOHAq and CS_2 in the cold (Gabriel a. Lauer, *B.* 23, 92). Crystals, v. sol. hot water and alcohol, insol. acids, sol. NaOHAq. Bromine-water at 100° produces $CH_2(NH_2).CH_2.CH_2.SO_3H$.

ψ - SULPHYDRO - PHENYL - AMIDO - (α) - NAPHTHYL-THIOBIAZOLE $C_{18}H_{13}N_3S_2$ *i.e.* $S<\begin{matrix}C(NHPh):N\\CS.N(C_{10}H_7)\end{matrix}>$. [255°]. Formed by mixing $NHPh.CS.NH.NHC_{10}H_7$ with $CSCl_2$ in benzene (Preund, *B.* 24, 4192). Colourless crystals, v. sol. acetone, sl. sol. alcohol.

ψ - SULPHYDRO - PHENYL - METHYL - BIAZOLE $O<\begin{matrix}CS.NPh\\CMe:N\end{matrix}$. [72°]. Formed from dichloro-phenyl-methyl-biazole dihydride and alcoholic ammonium sulphide (Freund a. Kuh, *B.* 23, 2837). Formed also from NHAc.NHPh and $CSCl_2$ (Freund a. Goldschmidt, *B.* 21, 2456). Prisms (from alcohol). Yields phenyl thiocarbimide on distilling with P_2S_5.

SULPHYDRO-PHENYL-GLYOXALINE $C_9H_8N_2S$ *i.e.* $\begin{matrix}CH:CH\\N:C(SH)\end{matrix}>NPh$. [181°]. Formed by boiling $NHPh.CS.NH.CH_2.CH(OEt)_2$ with dilute H_2SO_4 (Wohl a. Marckwald, *B.* 22, 569, 1353). Needles (from hot water), v. sol. NaOHAq, insol. NH_3Aq.—Salts: $C_9H_7AgN_2S$.—$B'_2H_2PtCl_6$: deep-red crystals.—B'MeI. [152°].

Methyl derivative $\begin{matrix}CH:CH\\N=C(SMe)\end{matrix}>NPh$. [54°]. Formed by treatment with alcoholic NaOH and MeI. White needles (from alcohol), insol. water.—$B'C_6H_3N_3O_7$.—$B'HNO_3$. Needles, v. e. sol. water.—B'MeI. [177°]. Crystalline rosettes (from water). Oxidised by dilute HNO_3 to a nitro- compound [116°].

ψ - SULPHYDRO - PHENYL - DI - METHYL - PYRIDINE DICARBOXYLIC ETHER $CS<\begin{matrix}CMe:C(CO_2Et)\\CMe:C(CO_2Et)\end{matrix}>NPh$. [245°]. Formed by heating $CS<\begin{matrix}CMe:C(CO_2Et)\\CMe:C(CO_2Et)\end{matrix}>O$ with aniline and HOAc (Guthzeit a. Epstein, *B.* 20, 2112). Sulphur-yellow crystals (from alcohol).

ψ - SULPHYDRO - PHENYL - NAPHTHYL - BIAZOLE $O<\begin{matrix}CS.NC_{10}H_7\\CPh:N\end{matrix}$. [164°]. Formed from $NHBz.NHC_{10}H_7$ and $CSCl_2$ in $CHCl_3$ (Preund, *B.* 24, 4186). Needles, v. sol. alcohol.

SULPHYDRO - PHENYL - QUINAZOLINE. *Dihydride* $C_6H_4<\begin{matrix}CH_2.NPh\\NH.CS\end{matrix}$. [197°]. Formed by warming ω-oxy-tolyl-phenyl-thio-urea with conc. HClAq (Söderbaum a. Widman, *B.* 22, 1671). Needles. — $B'_2H_2PtCl_6$. [219°]. — $B'HAuCl_4$. [197°]. Needles.

Reference.—OXY-SULPHYDRO-PHENYL-QUINAZOLINE.

DI-SULPHYDRO-DI-PHENYL-THIO-UREA. *Di-methyl derivative* $CS(NH.C_6H_4.SMe)_2$. [162°]. Formed by boiling [1:2] $NH_2.C_6H_4.SMe$ with CS_2 and solid KOH (Hofmann, *B.* 20, 1794). Prisms, v. sl. sol. alcohol. Forms, when heated, $SCN.C_6H_4.SMe$ (c. 270°).

β-SULPHYDRO-PROPIONIC ACID $CH_2(SH).CH_2.CO_2H$. Formed from β-iodopropionic acid and KSH. Got also by reducing sulphido-dipropionic acid (Lovén, *J. pr.* [2] 29, 376). Liquid, miscible with water, alcohol, and ether. Easily oxidised by air. $CuSO_4$ gives a pale-violet pp., but if not in excess it forms a yellow pp. of $CH_2(SCu).CH_2.CO_2H$ while $S(C_2H_4.CO_2H)_2$ remains dissolved. —$Hg(S.C_2H_4.CO_2H)_2$. Scales. —$Bi(S.C_2H_4.CO_2H)_3$.

Isomeride.—Thiolactic acid.

SULPHYDRO - PROPYL - PHTHALIMIDE $C_8H_4O_2:N.CH_2.CH_2.CH_2SH$. [48°]. Formed by heating γ-bromo-propyl-phthalimide with KSHAq at 100° (Gabriel a. Lauer, *B.* 23, 88). Needles (from hot ligroïn). Fuming HClAq at 180° forms phthalic acid and γ-amido-propyl mercaptan.

(*Py.* 3)-**SULPHYDRO-QUINOLINE**  $C_6H_4\left\langle\begin{array}{l}CH:CH\\N:C.SH\end{array}\right.$ [174°]. Formed by heating (*Py.* 3)-oxy-quinoline with P_2S_5 at 140° (Roos, *B.* 21, 620). Yellow plates (from dilute alcohol), insol. cold water, sol. acids and alkalis. Oxidised by H_2O_2 to $C_{18}H_{12}N_2S_2$ [137°]. EtI and alcohol at 100° form $C_9H_6(SEt)NHI$ [154°], which yields $(C_9H_6(SEt)N)_2H_2PtCl_6aq$, melting, when anhydrous, at 190°.

SULPHYDRO - THIAZOLE. *Dihydride*  $\left.\begin{array}{l}CH_2.S\\CH_2.N\end{array}\right\rangle C.SH$. [107°]. Formed from bromo-ethyl-amine, NaOH, CS_2, and alcohol (Gabriel, *B.* 22, 1152). Needles, sol. alcohol and hot water. Sol. alkalis. Bromine-water yields taurine. Alcohol, KOH and MeI form oily  $C_2H_4\left\langle\begin{array}{c}S\\N\end{array}\right\rangle C.SMe$ (217°), insol. alkalis but sol. acids.

Reference.—Oxy-sulphydro-thiazole.

SULPHYDRO-ACETONE. The compound $CH_3.C(SEt)_2.CH_2SEt$ (170°) is formed by passing gaseous HCl into $CH_3.CO.CH_2SEt$ mixed with mercaptan (Autenrieth, *B.* 24, 167).

ω-SULPHYDRO-*o*-TOLUIC ACID. *Methyl derivative* $CH_2(SMe).C_6H_4.CO_2H$. [138°]. Formed by the action of conc. HClAq at 100° on the nitrile $CH_2(SMe).C_6H_4CN$ (278°), which is got by dissolving thio-phthalimidine in alcoholic KOH and adding MeI (Day a. Gabriel, *B.* 23, 2484). Light oil.

SULPHYDRO-ISOVALERIC ACID $CHPr(SH).CO_2H$. Formed from α-bromo-isovaleric acid and alcoholic KSH (Duvillier, *Bl.* [2] 30, 507).

SUPER. *Use of this prefix applied to inorganic compounds.* The prefix *super* is sometimes employed to denote the presence in compounds of relatively more of the characteristic negative element, or elements, than is found in the normal compounds of the same form. The prefix *per* is, however, much oftener used than *super.* It has been proposed by Mendeléeff to designate the oxides that belong to the same type as H_2O_2 *superoxides*, to distinguish them from other peroxides (*v.* Oxides, vol. iii. p. 660).

M. M. P. M.

SUPERBIN. A poisonous substance contained in the root of *Gloriosa superba* (Warden, *Ph.* [3] 11, 495).

SYCOCERYL ALCOHOL $C_{32}H_{54}O$. *[114°]. Occurs as acetyl derivative in the resin of Ficus rubiginosa* (De la Rue a. Müller, *C. J.* 5, 62; Rennie a. Goyder, *C. J.* 61, 916). Thin crystals (from alcohol), insol. water and alkalis. BzCl yields a crystalline benzoyl derivative.

Acetyl derivative $C_{34}H_{56}O_2$. [121°]. Flat six-sided tablets, v. sol. hot alcohol, ether, and chloroform.

SYLVANE C_5H_6O. (63°). S.G. ·887. Got by distilling pine-wood (Atterberg, *B.* 13, 879). Liquid, readily resinified. Oxidised by $KMnO_4$ to acetic acid. Not attacked by Na, alkalis, or Ac_2O. HCl passed into its ethereal solution forms a small quantity of $C_{15}H_{22}O$, a liquid boiling at 240°.

SYLVANE-ACETIC ACID *v.* Methyl-furfuryl-acetic acid.

SYLVANE - CARBOXY-ACETIC ACID *v.* Methyl-carboxy-furfuryl-acetic acid and Methronic acid.

SYLVESTRENE *v.* Terpenes.

SYLVIC ACID C = 78·7 p.c. H = 9·7 p.c. [c. 162°]. $[\alpha]_D = -53°$. This acid is obtained from colophony by repeated crystallisation from dilute alcohol, and is perhaps identical with abietic acid (Liebermann, *B.* 17, 1884; Haller, *B.* 18, 2166). By heating with HI and P it is converted into a terpene $C_{10}H_{16}$. Sylvic acid appears also to be formed by the action of gaseous HCl on an ethereal solution of dextro-pimaric acid (Vesterberg, *B.* 19, 2173). A sylvic acid $C_{20}H_{30}O_2$ is described by Maly (*Sitz. W.* 44, 121) as formed by adding dilute H_2SO_4 or gaseous HCl to a solution of abietic acid. Duvernoy (*A.* 148, 147) obtained a sylvic acid [129°] by distilling pimaric acid *in vacuo*.

Isosylvic anhydride $C_{40}H_{58}O_3$. (250° at 30 mm.). $\alpha_D = +63°$. Got by distilling rosin *in vacuo* (Bischoff, *B.* 23, 1921). Colourless, brittle, microcrystalline substance, insol. water, v. sol. alcohol and ether. Isosylvic acid [62°] is ppd. on adding dilute HOAc to its solution in potash.

SYLVINOLIC ACID $C_{25}H_{38}O_4$? [130°]. Formed, together with sylvic acid, by saturating an alcoholic solution of abietic acid with HCl (Maly, *Sitz. W.* [2] 44, 121). Amorphous powder, v. sol. alcohol and ether.—CaA″.—Ag_2A'': pulverulent pp., insol. NH_3Aq.

SYMBOLS. Symbols are employed to express the composition, and, as far as possible, the interactions, of compounds; *v.* Equations, chemical (vol. ii. p. 433), Formulæ (vol. ii. p. 572), Isomerism (vol. iii. p. 79), and *cf.* Optical methods (this vol. p. 253). M. M. P. M.

SYNANTHRENE $C_{14}H_{10}$. *Phosene.* Occurs in crude anthracene (Zeidler, *A.* 191, 298; *cf.* Barbier, *A. Ch.* [5] 7, 526). Yellowish-white plates. Yields a di-bromo- derivative $C_{14}H_8Br_2$ [175°], crystallising in minute yellow needles, sol. alcohol (difference from di-bromo-anthracene). Di-bromo-synanthrene is oxidised by CrO_3 and HOAc to a quinone (?) [240°-250°].

SYNANTHRIN *v.* Inulin.

SYNTHESIS. The building up of compounds from their elements, or from groups of elements.

SYNTONIN *v.* PROTEÏDS.

SYRINGIN $C_{17}H_{24}O_9$. [191°]. *Dimethoxy-coniferin.* Occurs in the bark of the lilac (*Syringa vulgaris*) and of the privet (*Ligustrum vulgare*) (Bernays, *J. pr.* 25, 121; Kromayer, *Ar. Ph.* [2] 108, 7; 109, 18, 216; 113, 19; Körner, *G.* 18, 215). White needles (containing aq), v. sl. sol. cold water, v. sol. alcohol, insol. ether. Its aqueous solution is slightly bitter, is lævorotatory, and does not ppt. metallic salts. Conc. HNO_3 gives a blood-red solution. Conc. HClAq forms a colourless solution, turning blue, and finally giving a blue pp. Conc. H_2SO_4 gives a yellowish-green colour, changing to violet-brown and, on pouring into water, giving a bright-blue solution, which soon deposits an azure powder. Does not reduce Fehling's solution. Decomposed by emulsin into glucose and syringenin. $KMnO_4$ yields glucosyringic acid. CrO_3 forms glucosyringic aldehyde.

Syringenin $C_{11}H_{14}O_4$ *i.e.* [5:3:4:1]? $C_6H_2(OMe)_2(OH).C_3H_4.OH$. Formed as above. Resembles coniferyl alcohol.

Glucosyringic acid $C_{15}H_{20}O_{10}$. [206°]. Formed as above. Needles or prisms (containing 2aq), sl. sol. cold water. Decomposed by dilute H_2SO_4 into syringic acid and glucose.

Syringic acid $C_6H_2(OH)(OMe)_2.CO_2H$. *Di-methyl derivative of gallic acid.* [202°]. Decomposes at 230° into CO_2 and the di-methyl derivative of pyrogallol.—$BaA'_2$3aq: four-sided tables.—MeA'aq. [83·5°]. Crystals, sol. Aq.

Methyl derivative $C_6H_2(OMe)_3.CO_2H$. [168°]. Needles. Yields $C_6H_3(OMe)_3$ when distilled with lime. Identical with the tri-methyl derivative of gallic acid.—MeA'. [82·5°]. Needles.

Glycosyringic aldehyde $C_{15}H_{20}O_9$. [162°]. Colourless, silky needles. Decomposed by emulsin or dilute H_2SO_4 into glucose and syringic aldehyde. Yields a phenyl-hydrazide [156°] and a crystalline oxim.

Syringic aldehyde $C_9H_{10}O_4$ *i.e.* $C_6H_2(OH)(OMe)_2.CHO$. [111·5°]. Small needles, smelling like vanillin. Turns brown in air. Reacts with phenyl-hydrazine, and combines with $NaHSO_3$.

T

TAIGUIC ACID *v.* Lapachic acid.

TALOMUCIC ACID $C_6H_{10}O_8$. [158°]. $[\alpha]_D = +29.4°$ at 20°. Formed from talonic acid and HNO_3 (S.G. 1·15) (Fischer, *B.* 24, 3625). Minute plates, v. e. sol. cold water and warm alcohol; v. sl. sol. ether. Converted by HCl and HBr at 150° into dehydromucic acid. Yields a phenyl-hydrazide [185°–190°]. Pyridine at 150° forms mucic acid.—CaA″: crystalline powder.

TALONIC ACID $C_6H_{12}O_7$. Formed by heating galactonic acid with pyridine at 150° (Fischer, *B.* 24, 3622). Purified by means of its brucine salt. Syrup, very soluble hot alcohol. Lævorotatory. Yields a phenyl-hydrazide $C_6H_{11}O_6(N_2H_2Ph)$ [c. 155°].—CaA′$_2$aq. Needles (from alcohol), v. e. sol. water.—Brucine salt. [130°–133°]. Crystals, v. sol. water.

TAMPICIN $C_{34}H_{54}O_{14}$. [130°]. A neutral substance resembling convolvulin, occurring in *Tampica Jalap* (Spirgatis, *N. R. P.* 19, 452). Resin, v. sol. alcohol and ether. Converted by hot baryta-water into amorphous tampicic acid $C_{34}H_{60}O_{17}$. Boiling dilute acids resolve tampicin into glucose (3 mols.) and tampicolic acid $C_{16}H_{32}O_3$, which crystallises from dilute alcohol in minute needles and forms NaA′ and EtA′, both being crystalline.

TANACETIN $C_{11}H_{16}O_4$. A bitter substance obtained from the leaves and flowers of the tansy (*Tanacetum vulgare*) (Leroy, *J. Chim. Med.* 21, 357; Leppig, *J.* 1882, 1175). Amorphous, sol. water and alcohol.

TANACETOGENIC ACID $C_9H_{14}O_2$. (114° at 15 mm.). Formed by the action of Br and (4 p.c.) NaOHAq on tanacetone (Semmler, *B.* 25, 3346). Oil, solidified below 0°.—AgA′.

TANACETONE $C_{10}H_{16}O$. (84·5° at 13 mm.). Occurs in oil of absinthe, thuja, and sage, constituting the chief part of absinthol, salviol, and (β)-thujol (Semmler, *B.* 25, 3343, 3350). Got from ethereal oil of *Tanacetum vulgare* by shaking with $NaHSO_3$, decomposing the crystalline product with Na_2CO_3, and distilling with steam. Oil, v. sol. alcohol and ether. Does not reduce ammoniacal $AgNO_3$. Dextrorotatory; $\alpha = 38\frac{1}{2}°$ in a 20 c.m. tube. S.G. ^{22} ·913. $\mu_D = 1·450$.

Reactions.—1. Br and KOHAq yield bromoform, hence it probably contains $CO.CH_3$.—2. Reduced in alcoholic solution by Na to tanacetyl alcohol $C_{10}H_{18}O$, (93° at 13 mm.), S.G. ^{22} ·925, $\mu_D = 1·4635$. This body does not combine with Br. With PCl_5 it yields tanacetyl chloride (72° at 10 mm.).—3. Oxidised by $KMnO_4$ to Tanacetketocarboxylic acid $C_{10}H_{16}O_3$. Needles [78°] (from ligroin) or plates [74·5°] (from water). Yields AgA′. Hydroxylamine yields $C_{10}H_{16}O_2(NOH)$ [103] when prepared from the needles and [169°] when got from the plates. The ketonic acid is oxidised by Br and NaOH to tanacetogen dicarboxylic acid $C_9H_{14}O_4$ [142°]. Plates (from water). This acid yields Ag_2A'' while Ac_2O yields the anhydride $C_9H_{12}O_3$ [55°], which gives isopropyl succinic acid [114°] when fused with potash.

Oxim $C_{10}H_{16}$:NOH. [52°]. (136° at 20 mm.). Reduced in alcoholic solution by Na to tanacetylamine $C_{10}H_{17}NH_2$ (80·5 at 14 mm.), S.G. ^{22} ·874, μ_D 1·462, which yields B′HCl, which when heated gives tanacetene $C_{10}H_{16}$ (65° at 14 mm.), S.G. ^{22} ·841, μ_D 1·476. Tanacetone oxim may be converted by warming with alcohol and dilute sulphuric acid into the cymidine $C_6H_2(C_3H_7)(NH_2)Me$ [1:3:4], whence nitrous acid forms carvacrol.

TANACETOPHORONE $C_9H_{14}O$. (90° at 13 mm.). S.G. ^{19} ·938. μ_D 1·482. Got by distilling tanacetogen dicarboxylic acid with soda-lime

(Semmler, *B.* 25, 3350). An oil, smelling like camphor-phorone. Reacts with hydroxyl-amine.

TANGHININ $C_{27}H_{40}O_8 2aq.$ [182°]. $[\alpha]_D = -67°$. Obtained from the kernels of *Tanghinia venenifera* of Madagascar (Arnaud, *C. R.* 108, 1255; 109, 701). Crystals (from alcohol), v. sl. sol. water, sl. sol. ether. Cardiac poison. Resinified by dilute acids. Baryta-water at 180° forms $C_{27}H_{44}O_{10}$.

TANNIN. TANNIC ACIDS. Under the above names are included a large series of compounds, occurring in the vegetable kingdom, of different constitutions, many of which have been very imperfectly studied. Their chief characteristics are their astringent taste and property of giving a dark-blue or green colouration with iron salts and a precipitate with a solution of gelatin. They all reduce solutions of the noble metals, and absorb oxygen in presence of alkalis. They are all aromatic derivatives, and yield on fusion with potash either pyrogallol or pyrocatechin. In some cases they have been synthetically prepared from these phenols and their derivatives, but in many cases the tannin appears to exist in the plant as a glucoside and attempts at a synthetical production have proved futile. Schiff (*B.* 15, 2590) prepared some of the tannins synthetically, and concluded that they were anhydro- compounds of gallic and protocatechuic acids respectively. Etti (*A.* 186, 332) and others have also, for example, synthetically prepared catechutannic acid by heating pyrocatechin with water or alkalis. Gallotannic acid was formerly believed to be a glucoside, but subsequent investigation showed that the amount of sugar present was variable, and Schiff (*A.* 170, 43) finally proved that, although existing in the plant as a very unstable glucoside, when it was isolated it had the constitution of an anhydro- acid formed by the removal of one molecule of water from two molecules of a trioxy-benzoic acid. He considered that in gallotannic acid the anhydride was formed thus:— $C_6H_2(OH)_3CO.O.C_6H_2(OH)_2COOH$, whilst C. Etti, who has similarly investigated the tannins of the formulæ $C_{17}H_{16}O_9$ and $C_{20}H_{20}O_9$ has proved that they also are not glucosides, and regards them as derivatives of a ketonic acid of the formula $C_6H_2(OH)_3.CO.C_6H(OH)_3COOH$. It would appear, then, possible to define the tannic acids as mono-carboxyl acids formed by condensation from two molecules of poly-oxy-benzoic acids and which exist as unstable glucosides in plants. The ease with which gallotannic acid is hydrolysed renders it probable that the difference in constitution between Schiff's and Etti's formulæ does actually exist, and renders it possible to subdivide the tannins into these two groups so soon as the different tannins have been re-examined from this point of view. The ketonic character of the tannins was established by Etti through noting that they reacted with phenyl-hydrazine and hydroxylamine.

The origin of tannin in plants has given rise to much debate. According to Waage (*Ph.* 1890; *Phar. Centr.* 1891, 247) its formation is similar to that of the conversion of glucose into starch. The plant removes one molecule H_2O from glucose for reserve purposes, and if under favourable circumstances three molecules H_2O can be removed, a body having the composition of a triketohexamethylene would be produced

$CH_2COCH_2COCH_2CO$. This constitution corresponds to the secondary form of phloroglucin. It is probable that the phloroglucin combines with the CO_2 in the nascent state produced by the respiration of the plant, and is thus converted into a carboxylic acid (gallic acid); two molecules of this acid by the removal of another molecule of water would then form tannin. Light and chlorophyll are necessary for the production of tannin.

Westermaier (*B. B.* 1887, 127–143) showed that with experiments made with *Quercus pedunculata* the tannin migrates downwards through the bark and the pith. Starch is always present, and it is probable that the starch only migrates in the form of tannin. The leaves of *Rumex patentia* and *Rheum rhaponticum* give both the starch and the tannin reactions. Schultze (*A. a.* 14, 525–526; *B. C.* 18, 137), by microchemical observations, also supports the view of Sachs and Heberland that the leaves of evergreens contain tannin as a winter reserve material. Tannin and starch only rarely occur simultaneously in the same cells. When the cells are rich in starch they contain a smaller amount of tannin, and *vice versâ*.

In the case of leaves containing fatty oils and tannin, the cells which contain the oil are free from tannin, and cells containing no oil are free from starch. Kraus (*B. C.* 330–334) also notes that the formation of tannin in leaves depends on the presence of light and CO_2, but believes that it acts more as a protecting agent either to prevent the plant from being eaten or rotting than as a reserve material. He points out that as fallen leaves contain as much tannin as they did during their best time of growth, the leaf tannin is of no value to the plant. Heckel a. Schlagdenhauffen (*Ph.* July 1892) note that the protecting leaf buds of certain species of gardenia contain a resinous substance which on analysis gives figures resembling cinchotannic acid. Both the gardenias and the cinchonas belong to the same order of plants (*cf.* Cross a. Bevan, *C. J.* 41, 106; Gardiner, *Ph.* [3] 14, 588; Braemer, *Les Tannoïdes*, Toulouse, 1890; Büsgen, *C. C.* 1890, 397).

Classification.—No satisfactory classification of these bodies exists. Wagner (*Fr.* 5, 1) divides them into pathological and physiological tannins. The former are chiefly glucosides, and precipitate gelatin, yield gallic acid when hydrolysed with dense sulphuric acid, and when heated alone form pyrogallol. The physiological tannins, on the other hand, form leather, and on distillation yield pyrocatechin. The old classification into iron-blueing and iron-greening tannins is found now to be untenable, as the presence of acids and salts modifies the colour which the tannins produce with $FeCl_3$, and the purity of many of the tannins examined by the earlier investigators cannot be guaranteed.

Reactions.—The oxidation of gallic and tannin acids by nitric acid of moderate dilution yields oxalic acid and two acids, probably trioxy-glutaric and trioxy-butyric. The acetyl *o*-quercitannic acid yields the same acids on oxidation (Böttinger, *A.* 257, 248–252). Metallic Na does not reduce gallic acid in absolute alcohol, but tannic acid similarly treated undergoes simple hydrolysis, the yield of gallic acid amounting to 60 p.c. of the weight of tannin. No reduction products could be prepared (Böttinger, *A.* 258, 252–260). Ammonia and zinc-dust at 60° convert both acids into benzoic acid. Dilute H_2SO_4 and Zn also form benzoic from gallic acid (Guignet, *C. R.* 113, 200–201).

The action of heat. Most tannins begin to blacken at 120°, and at 160° decomposition into metagallic acid, and either pyrogallol or pyrocatechin, takes place. Those which yield pyrogallol usually also form a 'bloom' on leather, and give a blue colour with $FeCl_3$. This class includes galls, sumac, chestnut, and oak bark. The pyrocatechin-yielding tannins do not form a 'bloom' on leather, give green compounds with $FeCl_3$, and include hemlock, catechu, rhatany, and mangrove (Trimble, *The Tannins*, 1892).

The products of the action of heat on the tannins are best obtained by allowing the heating to take place on the material suspended in glycerin (1 g. in 5 c.c. glycerin). After heating to 200° for 30 minutes, dilute with water, and extract with ether. The ethereal extract contains either pyrogallol or pyrocatechin. The tannin must be freed from gallic acid and catechin before subjecting it to this test by previous ether extraction of the aqueous solution.

The action of dilute acids. 2 p.c. absolute HCl at 100° in sealed tubes decomposes the tannins; insoluble ellagic acid, anhydrides, or phlobaphenes separate, and the filtrate contains gallic acid, glucose, and unaltered tannin. Glucose should be removed from the tannin by repeated lead acetate precipitation before this treatment, or the amount of glucose before and after hydrolysis may be determined by Fehling's solution (Wehmer a. Tollens, *A.* 243, 327).

The action of alkalis. The pyrocatechin-yielding tannins on heating with alkali yield protocatechuic acid, and either phloroglucin or acetic acid. The pyrogallol-yielding tannins form gallic and ellagic acids (20 g. with 150 c.c. of KHO solution, sp.gr. 1·2 for 3 hours are convenient quantities (Trimble, *The Tannins*).

The tannins in the bark of oak, chestnut, horsechestnut, fir, &c., are precipitated in brominated condition by bromine water; tannin, sumach tannin, and oak wood tannin are not so precipitated (Böttinger, *A.* 240, 330). From oak tannin, Böttinger, by treating with acetic anhydride, has formed an acetyl-*o*-compound of the formula $C_{15}H_7Ac_5O_9$, and from it two bromo-derivatives $C_{15}H_{10}BrAcO_9$ and $C_{15}H_7Br_4AcO_9$ (*B.* 20, 761–766). A benzoyl-*o*-derivative has also been obtained from tannin by treatment with conc. NaOHAq and benzoyl chloride (Böttinger, *A.* 254, 370). The same author has attempted to prepare cyanhydrins, but without success. Well-dried tannic acid heated with anhydrous HCN in sealed tubes yielded only an amide of gallic acid. Treated with hydroxylamine no oxim was formed, but only gallic acid (*A.* 259, 132–136). With pure tannin phenyl-hydrazine, however, forms derivatives which do not crystallise, CO_2 and N being evolved at the same time. The tannins experimented upon were extracts of sumach, divi divi, oak wood, oak bark and pine bark; the dry precipitates contained phenyl-hydrazine derivatives of tannic and gallic acids, osazones of dextrose and lævulose, and caramel (*A.* 259, 125–132; *A.* 256, 342).

Tannin solutions are very unstable, undergoing hydrolysis into gallic acid on standing. The hydrolysis into gallic acid is almost quantitative when the acid is dissolved in conc. H_2SO_4 and then water added (Böttinger, *A.* 254, 378). When heated with $KHSO_4$ and glycerin to 119°–200° and the melt extracted with water, a residue is left soluble in absolute alcohol which contains two new acids of the composition $C_{14}H_{14}O_7$Aq and called hydrotannic and isotannic acids respectively. The former, which is the less soluble in alcohol, forms with Ac_2O a tetra-acetyl- compound while the iso- acid forms a brown tri-acetyl- compound (*C. J.* 1892, 181).

Preparation of tannic acid for pharmaceutical purposes. Pelouze in 1834 first suggested the extraction of tannic acid from galls by percolation with ether, and this method is still in use. The powdered galls are placed in a closed percolator with commercial ether containing alcohol and water. The ethereal layer contains gallic and ellagic acids, together with resins and fats and a small portion of the tannic acid; the lower aqueous solution contains nearly pure tannic acid. The percolation is stopped when the lower layer ceases to increase in volume. The B. P. method consists in taking the damp galls, macerating with commercial ether, and expressing through muslin (Leconnet a. Dominé). The purest acid is obtained when 10 pts. powdered galls are allowed to stand two days covered in a percolator with a mixture of 12 pts. ether and 3 pts. alcohol. At the end of this time the percolation is commenced until 10 pts. are obtained. One-third its volume of water is then added, and the mixture well agitated. The aqueous layer contains nearly pure tannic acid, and is evaporated rapidly *in vacuo*. The commercial acid is known under the names of ether-tannin, alcohol-tannin, or water-tannin, according to the method of extraction adopted on a large scale.

Purification.—Petroleum ether percolation removes fat, wax, and some of the colouring matter. Solution in water removes resin, and, after decantation, sodium chloride precipitates the acid. Trimble adds lead acetate to the aqueous solution to precipitate colouring matter, filters, and extracts with acetic ether. The acid is re-dissolved in water, and extracted with ether to remove the last traces of gallic acid, and the aqueous solution finally dried *in vacuo*.

Detection.—1. Dilute H_2SO_4 or HCl precipitates conc. solutions.—2. $FeCl_3$, a blue or green precipitate destroyed by long boiling, sol. weak mineral acids.—3. Lime-water precipitates the Ca salt. 4. Cinchonine sulphate precipitates white cinchonine tannate.—5. Gelatin forms leather and albumen also gives a precipitate. Alum and NH_4Cl render the precipitation more complete. 6. An alcoholic solution of thymol, followed by conc. H_2SO_4, yields a rose-coloured turbid solution (pyrogallol violet; gallic acid gives no colour: Saul, *Ph.* [3] 17, 387).—7. Iodine in presence of neutral salts gives a purple colouration (Nasser). 8. Acetate of lead acidulated with acetic acid ppts. tannic and not gallic acid (Guyard, *Bl.* 2, 41, 336).—9. NH_4Cl and NH_3 give a white precipitate rapidly becoming red, gallic acid a red colour-tion only.—10. Cl water and NH_3 give a red colouration both with gallic and tannic acids.—11. K_4FeCy_6 gives a similar reaction (Rawson, *C. N.* 59, 52-53).—12. In plants, Moll (*A. a.* 12, 496) detects tannins micro-chemically by treatment with 7 p.c. copper acetate for some days, then cuts sections, treats with a drop of 0·05 p.c. ferric acetate, washes with water and then alcohol to remove chlorophyll, and mounts in glycerin and looks for blue or green stain.—13. KCN gives a green colouration with tannin and none with gallic acid.—14. $K_2Cr_2O_7$ gives a brown pp. with most tannins.—15. Saturated solutions of NaCl, $CaCl_2$, KOAc, and a number of other salts ppt. tannins from solution. —16. Conc. H_2SO_4 dissolves the dry tannins with a yellow colour, and on heating forms dark-red rufigallic acid and then black metagallic acid.—17. HNO_3 forms a yellow colour, and finally oxidises them to oxalic acid.—18. As_2O_5 heated with the dry tannins converts most into ellagic acid.—19. Most tannins are ppd. by the alkaloids.

Estimation of tannic acid. The methods devised for the estimation of tannic acid in vegetable extracts are very numerous, and may be grouped under the following heads:—

1. Gelatin or hide-powder absorption.
2. Titration with permanganate.
3. Precipitation with metallic salts.
4. Methods not included in the above.

For details of these various processes, *vide* Proctor, *Textbook of Tanning*; Trimble, *The Tannins*; Thorpe's DICTIONARY OF APPLIED CHEMISTRY, and Rideal, *Chemical Notes on Modern Tanning*; *The Assay of Tanning Materials*; *Industries*, vol. xi. pp. 19, 139, 451. The two methods most generally employed are the hide-powder method and Löwenthal's permanganate process.

The hide-powder method is conducted as follows. A weighed quantity of the material is extracted with water and made up to a known volume. 100 c.c. of this solution is then evaporated, dried, and weighed to give the total solids present in the extract. Another portion of the same solution is agitated with, aspirated, or filtered through hide powder, and the total solids left in 100 c.c. of the solution again determined. The difference gives the quantity of tannic acid or matter which combines with gelatin per 100 c.c. of the solution (*Fr.* 24, 271).

The modified Löwenthal's process, which is now official in Germany, requires a standard solution of permanganate whose indigo value is known. A measured volume of the tannin solution, together with a known volume of indigo solution, is then titrated with the permanganate solution. Another equal volume of the tannin solution is then agitated with hide powder or shaken with a gelatin and alum solution and filtered, and the filtrate, after indigo solution of known amount has been added, is titrated with the permanganate solution. The difference in the quantity of permanganate consumed is a measure of the tannic acid present. The various tannins of commerce have different permanganate values; it is, therefore, necessary to standardise the permanganate for different tannin materials (Löwenthal, *Fr.* 16, 33; Kathreiner, *Fr.* 18, 118; Simaud, *Fr.* 22, 595; Schroeder, *Fr.* 25, 121).

Gallotannic acid $C_{14}H_{10}O_9$. Occurs in gall nuts and sumach.

Constitution.—$C_6H_2(OH)_3.CO.O.C_6H_2(OH)_2.COOH$ (Schiff, *A.* 170, 43; Paul a. Kingzett, *C. J.* 33, 217).

Solubility.—Sol. acetone, glycerin, and oils; insol. CS_2, $CHCl_3$, petroleum, and C_6H_6.

Compounds.—With gelatin contains 16·5 p.c. nitrogen = 34 p.c. tannin (Böttinger, *A.* 244, 227). (For other nitrogen values of gelatin-tannin compounds in leather, *v.* Rideal a. Trotter, *S. C. I.* 1891.) Penta-acetyl-compound $C_6H_2(OAcO)_3CO.O.C_6H_2(OAcO)_2COOH$ [137°]. (Böttinger, *B.* 17, 1504).

Action of heat.—At 215° it forms pyrogallol, CO_2, and a trace of metagallic acid $C_6H_4O_2$. Strong heating at 240°–250° forms chiefly metagallic acid (Pelouze, *A.* 10, 159). Cold HNO_3 forms oxalic, trioxyglutaric, and trioxybutyric acids (Böttinger, *A.* 257, 248). Boiling with KHO forms tannomelanic acid $C_6H_4O_3$; cold KHO and air form tannoxylic acid $C_7H_6O_6$ (Büchner, *A.* 53, 373). Hydrolysed by dil. H_2SO_4 to gallic acid. Ferments also form gallic acid (van Tieghem, *C. R.* 65, 1092).

Oak bark. Tannic acid $C_{17}H_{16}O_9$.

Preparation.—The bark is extracted with alcohol, and the extract agitated with acetic ether and ether. Evaporate off ether, separate the precipitate of ellagic acid, and from residue separate gallic acid from the tannic acid by acetic ether and ether.

Properties.—Reddish-white powder. Sol. alcohol and acetic ether. Sl. sol. ether and water. Heated to 130°–140°C. it forms an anhydride $C_{34}H_{30}O_{17}$ which is sl. sol. water; sol. alcohol and alkalis, and with conc. H_2SO_4 gives a second anhydride $C_{34}H_{25}O_{16}$. Heated with conc. HCl it evolves CH_3Cl, gives also the iodoform reaction. On dry distillation it forms pyrocatechin. Fused with KOH yields protocatechuic acid, pyrocatechol, and traces of phloroglucin (Etti, *M.* 1880, 262–278). When boiled with ether the above anhydrides form a third anhydride $C_{34}H_{26}O_{15}$ (*M.* 1883, 512). Other anhydrides analysed by Etti are $C_{40}H_{38}O_{17}$, $C_{40}H_{36}O_{16}$, $C_{40}H_{34}O_{15}$, and $C_{40}H_{32}O_{14}$. Forms two hydrates (Löwe, *C. J.* 40, 901).

Salts. With Ca, Ba, and Pb; analysed by Etti and Löwe (*l.c.*).

Derivatives.—Oak-red $C_{14}H_{10}O_8\frac{1}{2}aq$ (Grabowski, *A.* 145, 2); $C_{38}H_{28}O_{17}$ (Böttinger, *A.* 240, 341). Böttinger has prepared various bromo-, acetyl-, and benzoyl-derivatives (*l.c.*) (Rochleder, *A.* 63, 205; Böttinger, *A.* 202, 270; *B.* 14, 1598; Löwe, *Fr.* 20, 210; Etti, *M.* 4, 514; Grabowski, *A.* 145, 2).

Fraxitannic acid $C_{26}H_{32}O_{14}$. In ash-leaves. Forms an anhydride $C_{26}H_{30}O_{15}$, a benzoyl-compound $C_{26}H_{26}O_{13}(OB_3)_4$, an acetyl-compound $C_{26}H_{28}(OAc)_4O_{10}$, a bromacetyl-compound $C_{26}H_{25}(OAc)_4Br_3O_{10}2aq$, and a similar nitro-compound. On heating with $Ba(OH)_2$ it forms protocatechuic acid and other products. On heating to 100° it loses 1 mol. H_2O, forming an anhydride $C_{26}H_{30}O_{13}$ (Gintl a. Reinitzer, *M.* 3, 745 *et seq.*).

The following table gives the source of the principal tannins which have been investigated, and references to the papers in which a description will be found.

Plant	Part	Name	Formula	Per cent.	References
Æsculus Hippocastanum	Nearly all parts	Horsechestnut tannin	$C_{26}H_{24}O_{12}$	—	Rochleder, *Sitz. B.* 53 [2] 478; 54 [2] 609
Æsculus Hippocastanum	Juice of berries	Rhamnotannic acid	$C_{26}H_{24}O_{13}.H_2O$	—	Rochleder, *Z.* 1867, 84
Algarobilla	Pods	Ellagotannic acid	$C_{14}H_{10}O_{10}$ *i.e.* $C_6H_2(OH)_3.CO.O.OC_6H_2(OH)_2.COOH$?	68·38	Godeffroy, *C. N.* 40, 144; Löwe, *Fr.* 14, 35; Zölffel, *Ar. Ph.* 229, 123; Hurst, *D. P. J.* 262, 288; Eitner, *D. P. J.* 244, 80
Alnus glutinosa	Wood	Alder tannin	$C_{27}H_{28}O_{11}$	—	Dreykorn a. Reichard, *D. P. J.* 195, 157
Anacahuita	Wood and bark	—	—	—	Buchner, *J.* 1861, 771
Asperula odorata	—	Aspertannic acid	$C_{14}H_{16}O_9$	—	Schwartz, *Sitz. B.* 6, 446

S. R.

TANSY OIL. The essential oil, obtained by distillation of the tansy (*Tanacetum vulgare*), contains 1 p.c. of a terpene $C_{10}H_{16}$ (155°–160°), 26 p.c. of an alcohol $C_{10}H_{18}O$, and 70 p.c. of 'tanacetyl hydride' $C_{10}H_{16}O$ (Bruylants, *J. Ph.* [4] 26, 393; *B.* 11, 449; *cf.* Persoz, *C. R.* 8, 433). Tanacetyl hydride $C_{10}H_{16}O$ (195°–196°), S.G. ·918, V.D. 5·1, is converted by H_2SO_4 into cymene. It reduces ammoniacal $AgNO_3$, forming a mirror. $NaHSO_3$ forms crystalline $C_{10}H_{15}NaSO_3$. Split up by water into the parent substances.

TANTALATES *v.* Tantalum, acids of, and their salts, p. 639.

TANTALUM. Ta. At. w. c. 182 (exact value not known). Mol. w. not known. Ta has not been isolated.

Occurrence.—Tantalates occur in a few rare minerals, generally associated with niobates; *tantalite* contains from 35 to 75 p.c. Ta_2O_5, *columbite* from 13 to 36 p.c., *yttrotantalite* from 6 to 47 p.c., and a mineral from Western Australia, recently analysed and called *stibio-tantalite*, c. 52 p.c., Ta_2O_5 (Goyder, *C. J.* 63, 1076).

History.—A short account of the researches that led to the identification of two distinct oxides in *tantalite* is given in the article Niobium (vol. iii. p. 505). Marignac (*C. R.* 60, 234, 1355) gave the formula Ta_2O_5 to oxide of Ta, which had been represented by Rose as TaO_2. Deville determined the V.D. of the chloride, and deduced the molecular formula $TaCl_5$ (*C. R.* 56, 891). By heating Na_2TaF_7 with Na, H. Rose (*P.* 99, 69) obtained a black powder, probably a mixture of Ta and oxides of Ta. Berzelius (*P.* 4, 6) also obtained very impure Ta; Marignac (*Ar. Sc.* 1868) failed to isolate approximately pure metal.

Preparation of impure Ta.—Very finely-powdered *tantalite* is fused with three times its weight of $KHSO_4$, in an iron or platinum crucible, until completely dissolved. After cooling, the fused substance is powdered and treated with boiling water, whereby sulphates of K, Fe, and Mn are dissolved out; the insoluble portion is washed, and then digested with yellow ammonium sulphide, whereby sulphides of Sn and W are dissolved, and FeS remains mixed with Ta_2O_5 and Nb_2O_5. The residue is washed thoroughly, and digested with HClAq to remove FeS, and the portion insoluble in HClAq is thoroughly washed with boiling water until it is white. The mixture of Ta_2O_5 and Nb_2O_5 thus obtained is dissolved in HFAq in a platinum dish, the solution is heated to boiling, and a quantity of KHF_2 is added equal to one-fourth of the weight of mixed Ta_2O_5 and Nb_2O_5 used; the liquid is evaporated until 1 g. of the mixed oxides is present in about 7 c.c. and allowed to cool; the prismatic crystals of K_2TaF_7 that separate are washed with cold water until the washings give a yellow pp., without any shade of red, after standing for two hours with tincture of galls. The K_2TaF_7 thus obtained is heated, in a platinum dish, with rather more than its weight of pure conc. H_2SO_4, whereby $KHSO_4$, HF, and Ta_2O_5 are formed; the HF is removed by heat, and the $KHSO_4$ by repeated washing with water (Berzelius, *P.* 4, 6; *cf.* H. Rose, *P.* 144, 64, 72).

Lawrence Smith (*Am.* 5, 44) recommends to warm 5 g. of very finely powdered *tantalite*, dried at 150°, in a platinum basin with a little water and 8 to 10 c.c. very conc. HFAq, to filter when reaction is completed, add a little water to the filtrate and evaporate nearly to dryness, to warm with excess of conc. pure H_2SO_4, and, after the acid has been almost wholly removed by heating, to place the residue in c. 500 c.c. dilute HNO_3Aq (L. M., *C. N.* 51, 289, 304), and boil until Ta_2O_5 and Nb_2O_5 are ppd. By dissolving in HFAq, adding KHF_2, and proceeding as described above, Ta_2O_5 is obtained free from Nb_2O_5.

The pure Ta_2O_5 obtained by one of the preceding methods is dissolved in HFAq, in a platinum vessel, the solution is heated to boiling, and 70·3 pts. by weight of KHF_2 are added for 100 pts. Ta_2O_5 used. The solution is evaporated and allowed to cool; the crystals of K_2TaF_7 are washed with a little cold water, dried, mixed with c. half their weight of potassium, and heated in an iron crucible, the mixture of K_2TaF_7 and K being covered with KCl. The contents of the crucible, after cooling, are added, little by little, to water; the black powder that separates is washed with water, and then with dilute alcohol and dried (Berzelius, *P.* 4, 6). The black powder is probably a mixture of Ta and oxides of the metal. Berzelius found that 100 pts. took up 17 pts. O when heated in air, 100 pts. pure Ta require 22 pts. O to form Ta_2O_5. H. Rose (*P.* 99, 69) obtained a black powder—probably Ta mixed with oxides—by reducing Na_2TaF_7 by heating with sodium.

Properties and Reactions.—The black powder obtained by Rose was a good conductor of electricity; it glowed when heated in the air, and slowly formed Ta_2O_5; it was insoluble in acids, except in HFAq, by which it was slowly dissolved; heated in a stream of Cl it burnt to $TaCl_5$. Oxidation was effected by molten alkalis or alkali carbonates. The S.G. of a specimen containing c. 40 p.c. acid sodium tantalate was c. 10·8.

The at. w. of Ta was determined by Marignac (*A.* 140, 153; *Suppl.* 4, 351 [1865]) by decomposing K_2TaF_7 and $(NH_4)_2TaF_7$ by H_2SO_4, and determining the quantities of Ta_2O_5 and K_2SO_4 produced. The values obtained varied from 180·1 to 185·2. H. Rose in 1856 (*P.* 99, 80) analysed $TaCl_5$ by decomposing by water, ppg. $Ta_2O_5.xH_2O$ by NH_3Aq, and estimating Cl in the filtrate. His results showed marked discrepancies.

Ta is metallic in its physical properties, so far as may be judged from the impure specimens that have been prepared. Ta_2O_5 dissolves in HFAq, probably forming TaF_5. No salts are known to be formed by replacing the H of an oxyacid by Ta. In all the salts of Ta that have been isolated, other than the haloid compounds, Ta forms part of the negative radicle. Ta is the fifth member of the even-series family of Group V.; it is closely related to Nb, and less closely to N, P, V, As, Sb, Di, Er, and Bi. The only compound of Ta whose V.D. has been determined is $TaCl_5$; in this molecule the atom of Ta is pentavalent (*v.* Nitrogen group of elements, vol. iii. p. 571).

Detection and Estimation.—Tantalum com-

pounds form potassium tantalate when fused with KOH, and the fused mass dissolves in water. The product obtained by fusion with NaOH dissolves in water to a clear liquid only after NaOH has been removed by washing, as sodium tantalate is insoluble in much NaOHAq. Addition of acid to an aqueous solution of an alkali tantalate, followed by boiling, ppts $Ta_2O_5.xH_2O$ more or less completely. By adding HClAq to a solution of an alkali tantalate, and placing zinc in the solution, no blue colour is produced (*cf.* NIOBIUM, DETECTION OF, vol. iii. p. 506). According to Levy (*C. R.* 103, 1074), an amethyst colour is produced by adding a very small quantity of Ta_2O_5 to a solution of resorcin in H_2SO_4Aq. Ta is estimated as Ta_2O_5; the process is sufficiently indicated under *Preparation*.

Tantalum, acids of, and their Salts. Ta_2O_5 reacts with molten alkalis, and alkali carbonates, to form salts which may be regarded as derived from various hydrates of Ta_2O_5. Two hydrates are obtained, $Ta_2O_5.2H_2O$ and $2Ta_2O_5.3H_2O$, by decomposing $TaCl_5$ by a little water, and by fusing Ta_2O_5 with $KHSO_4$ and washing with water (*v.* TANTALUM, OXIDES AND HYDRATED OXIDES OF, p. 640). The first of these hydrates may be called *pyrotantalic acid* $H_4Ta_2O_7$, corresponding with $H_4P_2O_7$; and the second may be formulated $H_6Ta_4O_{13}$. The tantalates that have been examined do not seem to be derived from either of these compounds, but from the hypothetical acids $HTaO_3$, corresponding with HPO_3 and HNO_3, and $H_8Ta_6O_{19}$ ($=3Ta_2O_5.4H_2O$). Tantalates are not produced by neutralising $Ta_2O_5.xH_2O$, but by fusing Ta_2O_5 with alkalis, or by double decomposition from alkali salts.

TANTALATES. The tantalates belong to the form $xTa_2O_5.yMO$, where $M = (NH_4)_2$, Mg, Hg_2, K_2, Ag_2, or Na_2; of those that have been fairly fully examined, some correspond with the metaphosphates and meta-niobates M^IXO_3, and others belong to the more complex form $M^I_8Ta_6O_{19}$. Some of the alkali tantalates dissolve slightly in water, the other tantalates are insoluble. *Fluotantalates* and *fluoxytantalates* are also known (*v. infra*). The tantalates have been investigated chiefly by H. Rose (*P.* 100, 417) and Marignac (*Bl.* [2] 6, 111, 118).

Ammonium tantalate. A pp. is obtained by adding NH_4Cl to solution of $Na_8Ta_6O_{19}.xH_2O$, but the composition of the pp. is not known with certainty.

Magnesium tantalate. By adding $MgSO_4$Aq to solution of $Na_8Ta_6O_{19}.xH_2O$ a crystalline pp. was obtained which, after drying at 100°, had the composition $Mg_4Ta_6O_{19}.9H_2O$. A crystalline Mg tantalate was obtained by Joly (*C. R.* 81, 266, 1266) by fusing Ta_2O_5 with $MgCl_2$.

Mercurous tantalate. A brown, amorphous compound, perhaps $Hg_8Ta_6O_{19}.xH_2O$, is formed by adding $HgNO_3$Aq to solution in water of $Na_8Ta_6O_{19}.xH_2O$.

Potassium tantalates. (1) $K_8Ta_6O_{19}.16H_2O$; this salt is obtained by fusing Ta_2O_5 with KOH, dissolving in water, and crystallising. (2) $KTaO_3$: this salt, *potassium metatantalate*, is formed by heating the other tantalate, alone or with $(NH_4)_2CO_3$, and then treating with water.

Silver tantalate. **The yellowish white pp. obtained by adding solution of a salt of Ag to solution of $Na_8Ta_6O_{19}.xH_2O$, and drying at 100°, has the composition $Ag_8Ta_6O_{19}.3H_2O$.**

Sodium tantalates. The *meta-salt* $NaTaO_3$ is obtained by fusing Ta_2O_5 with Na_2CO_3, and washing with water. A salt of the composition $Na_8Ta_6O_{19}.xH_2O$ ($x = 25$ and 30) is prepared by fusing Ta_2O_5 with NaOH, dissolving in water, and crystallising.

FLUOTANTALATES. (*Tantalifluorides.*) These salts may be regarded as compounds of TaF_5 with metallic fluorides, or as metallic derivatives of the hypothetical acid H_2TaF_7; they are prepared by dissolving Ta_2O_5 in HFAq, adding metallic fluorides, and crystallising; some of them are formed by dissolving Ta_2O_5 and a metallic oxide in HFAq (Marignac, *A. Ch.* [4] 9, 276; Berzelius, *P.* 4, 6).

Ammonium fluotantalate $(NH_4)_2TaF_7$ is obtained by evaporating a solution of NH_4F in solution of TaF_5 in HFAq, and evaporating; the salt is crystalline and easily soluble in water.

Copper fluotantalate $CuTaF_7$ forms blue, deliquescent, rhombic prisms; it is prepared by dissolving CuO and Ta_2O_5 in excess of HFAq, and evaporating.

Potassium fluotantalate K_2TaF_7 forms white needles by dissolving KHF_2 in solution of Ta_2O_5 in HFAq, evaporating, and crystallising from hot water. The salt is very slightly soluble in cold water, but dissolves easily in hot water. On long boiling, K_2TaF_7Aq gives a white pp., probably having the composition $K_4Ta_4O_5F_{14}$ ($=2TaF_5.Ta_2O_5.4KF$). By dissolving K_2TaF_7 in warm 4 p.c. H_2O_2Aq with a little HFAq and allowing to cool, Piccini (*Zeit. für anorg. Chemie*, 2, 21) obtained crystals of the *fluoxytantalate* $K_2TaO_2F_5.H_2O$ ($=TaO_2F_3.2KF.H_2O$).

Sodium fluotantalate $Na_2TaF_7.H_2O$; obtained, as white crystals, by dissolving $Na_8Ta_6O_{19}$ in HFAq, evaporating, and drying at 100° the salt that separates.

Zinc fluotantalate $ZnTaF_7.7H_2O$; a deliquescent salt, obtained by dissolving ZnO and Ta_2O_5 in excess of HFAq and crystallising.

Tantalum, alloys of. By heating K_2TaF_7 with Al, and washing with HClAq, Marignac (*P.* 100, 145) obtained a grey powder, S.G. 7·02. By heating to whiteness, in a carbon crucible, a mixture of Ta_2O_5 and iron filings, an alloy of Ta and Fe was obtained resembling pig iron (Gahn, Berzelius a. Eggertz, *S.* 16, 437).

Tantalum, bromide of, $TaBr_5$. A yellowish, crystalline compound, obtained by heating a mixture of dry Ta_2O_5 and C in vapour of Br, and removing excess of Br by a long-continued stream of dry CO_2; decomposed by water to HBrAq and $Ta_2O_5.xH_2O$ (H. Rose, *P.* 90, 456; 99, 75). The conditions of preparation are similar to those in making $TaCl_5$ (*q. v.*).

Tantalum, carbide of. By heating TaN (*v.* TANTALUM NITRIDE) with C to the melting-point of steel, N is given off and the nitride is partly converted into brass-yellow coloured TaC_2 (Joly, *Bl.* [2] 25, 206).

Tantalum, carbonitride of. Joly (*Bl.* [2] 25, 206) obtained a substance, to which he gave the formula 10TaC.TaN, by very strongly heating a mixture of Ta_2O_5 with C and soda.

Tantalum, chloride of, $TaCl_5$. Mol. w. c. 359 (not determined with great accuracy, as at. w. of Ta is doubtful). V.D. 185 at 360° (Deville a. Troost, *C. R.* 64, 294). Melts at 211°, and boils at 242° at 753 mm. pressure (D. a. T., *l.c.*). Only one chloride of Ta has been isolated.

Preparation.—About 5 g. pure dry Ta_2O_5 is mixed with a considerable excess of dry sugar or starch, and the mixture is completely charred by heating in a closed crucible; the charred mass is broken into small pieces, which are heated to redness and placed, while red hot, in a rather wide tube of hard glass that is quickly heated to redness while a stream of thoroughly dried CO_2 is passed through it as long as any trace of moisture is given off from the contents of the tube; the tube is then allowed to cool, the current of dry CO_2 being maintained; when the tube is cold a stream of dry Cl is passed through it, and when every part of the apparatus is filled with Cl (but not until then) the contents of the tube are heated. $TaCl_5$ forms immediately behind the carbonaceous matter, as a pale-yellow solid; when the reaction has entirely ceased and CO is no longer evolved, the $TaCl_5$ may be sublimed into another part of the tube, a plentiful stream of dry Cl being maintained during the process. If sublimation is attempted before the whole of the Ta_2O_5 has been chlorinated, a part of the $TaCl_5$ is decomposed by the CO, with re-formation of Ta_2O_5. If there should be any air in the tube during the process a white sublimate is formed which is probably an oxychloride (H. Rose, *P.* 90, 456; 99, 75). Should the Ta_2O_5 used contain any WO_3, the sublimate obtained is reddish; by gently heating, the greater part of the red $WOCl_4$ may be removed, as it is more volatile than $TaCl_5$.

Demarçay obtained $TaCl_5$ by passing vapour of CCl_4 over Ta_2O_5 heated to redness (*C. R.* 104, 111).

Properties and Reactions.—Pale-yellow prismatic needles, melting at 211°, and boiling at 242° under the pressure of 753 mm.; begins to vaporise at 144°; V.D. 185 at 360° (Deville a. Troost, *C. R.* 64, 294). Decomposes in ordinary air, giving off HCl and becoming covered with a crust of crystalline Ta_2O_5. Decomposed entirely by water to HClAq and $Ta_2O_5.xH_2O$. Conc. H_2SO_4 causes evolution of HCl, and forms a somewhat turbid solution from which $Ta_2O_5.xH_2O$ separates on boiling; by adding water to this solution, and boiling, the whole of the Ta is precipitated as $Ta_2O_5.xH_2O$. Conc. HClAq reacts similarly to H_2SO_4, but only a portion of the $Ta_2O_5.xH_2O$ is ppd. on adding water and boiling. $TaCl_5$ is partly dissolved by heating with KOHAq. $TaCl_5$ is soluble in absolute alcohol; H_2SO_4Aq does not ppt. $Ta_2O_5.xH_2O$ from this solution.

No double compounds of $TaCl_5$ with KCl or NaCl—similar to those of TaF_5—have been obtained.

Tantalum, fluoride of. $Ta_2O_5.xH_2O$ dissolves in HFAq; neither boiling, nor adding H_2SO_4Aq to the solution, ppts. Ta_2O_5. The solution in HFAq gives off vapours on evaporation that probably contain TaF_5; by evaporating at a low temperature, Rose obtained crystals that dissolved easily in water, and were partly vaporised when heated, leaving some Ta_2O_5 (*P.* 90, 456; 99, 75). By evaporating *in vacuo* a solution of $Ta_2O_5.xH_2O$ in HFAq, Marignac obtained a white amorphous mass—probably an oxyfluoride—and then small crystals that were likely TaF_5.

TaF_5 combines with some metallic fluorides, forming *fluotantalates* (*q.v.*, p. 639).

Tantalum, haloid compounds of. The only haloid compounds of Ta that have been isolated are $TaCl_5$ and $TaBr_5$. The former has been gasified, and the formula is molecular. TaF_5 also probably exists in solution of $Ta_2O_5.xH_2O$ in HFAq. There is no reaction between I and Ta_2O_5 mixed with C even at a very high temperature. $TaCl_5$ and $TaBr_5$ are readily decomposed by water, with formation of $Ta_2O_5.xH_2O$ and HXAq. Double compounds of TaF_5 with some metallic fluorides are known; they belong to the form $M^I_2TaF_7$ (*v.* FLUOTANTALATES). Oxyhaloid compounds probably exist, but none has been isolated with certainty.

Tantalum, nitrides of. $TaCl_5$ absorbs NH_3 at the ordinary temperature; by heating the product in NH_3, Joly (*Bl.* [2] 25, 206) obtained an amorphous, yellow solid, to which he gave the formula Ta_3N_5. By heating this yellow solid to redness in very dry NH_3, a black solid was obtained which, after washing with water and drying, had the composition TaN. This black solid conducts electricity; heated in air it burns to Ta_2O_5; NH_3 is given off by the action of molten KOH; it is insoluble in acids, except in a mixture of HFAq and HNO_3Aq (Joly, *l.c.*; *cf.* H. Rose, *P.* 100, 166).

Tantalum, nitrocarbide of; *v.* TANTALUM CARBONITRIDE, p. 639.

Tantalum, oxides and hydrated oxides of. The oxide Ta_2O_5 has been isolated, and also a hydrate of this oxide $Ta_2O_5.2H_2O$, and probably also another hydrate $2Ta_2O_5.3H_2O$. The existence of another oxide, TaO_2, is doubtful.

TANTALUM PENTOXIDE Ta_2O_5. (*Tantalic anhydride. Tantalic oxide.*) The preparation of this compound from *tantalite* is described at the the beginning of this article under *Preparation of tantalum* (p. 638). Ta_2O_5 is also obtained by decomposing $TaCl_5$ by water, or by adding H_2SO_4Aq to solution of a tantalate and boiling, and then heating the $Ta_2O_5.xH_2O$ thus ppd. Ta_2O_5 is a white powder; it has not been fused; by heating with boric acid or microcosmic salt in a porcelain oven it is obtained in rhombic prisms (Ebelmen, *A. Ch.* [3] 33, 34; Nordenskjöld a. Chydenius, *J.* 1860. 145). S.G. c. 7·6 (Marignac, *Ar. Sc.* 1868; Deville, *C. R.* 56, 894). Ta_2O_5 is insoluble in acids except HFAq; after being very strongly heated, it is insoluble in HFAq. Ta_2O_5 dissolves in molten alkalis, also in molten $KHSO_4$ (*v.* TANTALATES, p. 639).

HYDRATES OF TANTALUM PENTOXIDE. By decomposing $TaCl_5$ by water, $Ta_2O_5.xH_2O$ is obtained, which, after very thorough washing with water, then with NH_3Aq to remove adhering HCl, and finally with water, and drying at 100°, gives off from 6 to 7·8 p.c. water when heated to redness. The formula $2Ta_2O_5.3H_2O$ requires 5·7 p.c. H_2O, and the formula $Ta_2O_5.H_2O$ requires 7·5 p.c. H_2O. It is doubtful whether one or more than one definite hydrate exists in this pp. When SO_2 is passed into a solution of $Na_8Ta_6O_{19}$, a pp. of $Ta_2O_5.xH_2O$ is obtained, which, when thoroughly washed and dried at 100°, is said to be $Ta_2O_5.2H_2O = H_4Ta_2O_7$ (H. Rose, *P.* 100, 417). Strong acids, such as H_2SO_4, HNO_3, and HCl, ppt. $Ta_2O_3.xH_2O$ apparently in combination with the acid used as precipitant from solutions of alkali tantalates; weak acids ppt. insoluble alkali tantalates.

Tantalum dioxide TaO_2. (*Tantalum tetroxide* [Ta_2O_4].) The isolation of this oxide is doubtful. Berzelius obtained a brown powder by heating Ta_2O_5 to redness in a carbon crucible; it was not dissolved by any acids, not even by a mixture of HNO_3Aq and HFAq; when strongly heated in air it gave Ta_2O_5 (*P.* 4, 20).

Tantalum, oxyfluoride of. The white powder formed by decomposing K_2TaF_7 by boiling water may be an oxyfluoride, according to Marignac (*A. Ch.* [4] 9, 276).

Tantalum, salts of. No salt has been isolated by replacing the H of acids, except HCl and HF, by Ta. When alkali tantalates are decomposed by strong acids such as HCl, HNO_3, or H_2SO_4, the ppd. $Ta_2O_3.xH_2O$ retains some of the acid used as precipitant; compounds of Ta_2O_5 with these acids are perhaps formed.

Tantalum, sulphide of. By strongly heating Ta_2O_5 in CS_2 vapour, also by heating to redness a mixture of vapour of $TaCl_5$ and H_2S, a yellowish black solid is obtained, which has the composition TaS_2 according to Bérzelius (*P.* 4, 6; *v.* also H. Rose, *P.* 99, 575). Roasted in air, this solid gives Ta_2O_5; heated in Cl it produces $TaCl_5$ and S_2Cl_2; conc. HNO_3Aq oxidises it to $Ta_2O_5.xH_2O$ and H_2SO_4Aq. TaS_2 does not combine with alkali sulphides (R., *l.c.*); fused with KOH, it forms K_2S and potassium tantalates. M. M. P. M.

TARCHONYL ALCOHOL $C_{50}H_{102}O$ (?). Obtained from the leaves of *Tarchonanthus camphoratus* by extracting with alcohol (Canzoneri a. Spica, *G.* 12, 227). Silvery scales, insol. water and ether. Converted by PCl_5 into a chloride [70°] crystallising in small plates (from alcohol).

TARCONINE *v.* vol. iii. p. 496.

TARNINE *v.* vol. iii. p. 497.

TARTARIC ACID $C_4H_6O_6$ *i.e.* $CO_2H.CH(OH).CH(OH).CO_2H$. *Dextro-tartaric acid. Di-oxy-succinic acid.* [135°]. S.G. 1·764 (Schiff, *A.* 113, 189); 1·74 (Buignet, *J.* 1861, 15); $\frac{7}{4}$ 1·7594 (Perkin). S. 115 at 0°; 132 at 15°; 343 at 100° (Leidie, *Fr.* 22, 269; *C. R.* 95, 87; *cf.* Schiff, *J.* 1859, 41; Maisch, *J.* 1865, 392). S. (alcohol) 25·6 at 15°. S. (ether) ·4 at 15° (Bourgoin, *Bl.* [2] 29, 214; *A. Ch.* [5] 13, 400). $[\alpha]_D = 15{\cdot}06 - {\cdot}131p$ in a *p* per cent. solution (Landolt, *B.* 6, 1075; Lippmann, *B.* 24, 3300). H.F. 372,000 (Von Rechenberg). *Heat of solution*: −3454 at 9° (Pickering, *C. J.* 51, 376).

Occurs free or as K or Ca salt in grape-juice, tamarinds, unripe mountain-ash berries, madder-root, potatoes, Jerusalem artichokes, sorrel, gherkins, mulberries, pine-apples, black pepper, the leaves of *Chelidonium majus*, the bulbs of *Scilla maritima*, in beet-juice, and in many other plants.

Formation.—1. Mostly together with racemic acid, by oxidation of saccharic acid, dextrose, cane-sugar, milk-sugar, starch, gum arabic, and sorbin by nitric acid (Dessaignes, *A. Suppl.* 2, 242; Hornemann, *J.* 1863, 381; Kiliani, *A.* 205, 175).—2. By the action of sodium-amalgam on an alcoholic solution of oxalic ether (Debus, *A.* 166, 124; *C. J.* 24, 376). The product is probably inactive tartaric acid.

Preparation.—Powdered chalk is added to a boiling solution of cream of tartar; the filtrate is ppd. by calcium chloride, and both pps. decomposed by the proper quantity of boiling dilute H_2SO_4. The filtrate from $CaSO_4$ is evaporated to crystallisation. It may be purified by saturating with $CaCO_3$, digesting with $ZnCl_2$, and decomposing the zinc salt by H_2S (Ficinus, *Ar. Ph.* [3] 14, 310).

Properties.—Monoclinic prisms, with hemihedral facets; $a:b:c = {\cdot}785:1:{\cdot}805$; $\beta = 79°\ 43'$. Dextrorotatory, the rotation being dependent on the concentration of the solution, and being also greatly affected by the presence of alcohols, acids, and other substances in the solution (Landolt, *B.* 13, 2329; Biot, *J.* 1850, 169; Pribram, *M.* 9, 485; *B.* 22, 6; Long, *Am. S.* 36, 351; Thomson, *J. pr.* [2] 35, 145). Sodium molybdate in the proportion of Na_2MoO_4 to $2C_4H_6O_6$ increases the rotation 37 times, while ammonium molybdate (1 mol.) increases the rotation of tartaric acid (3 mols.) 56 times (Gernez, *C. R.* 104, 783; 105, 803). Lithium and magnesium molybdate also increase the rotation. Sodium tungstate also increases the rotation, the maximum effect being 22 times (Gernez, *C. R.* 106, 1527; 108, 942). Crystals of tartaric acid are strongly pyro-electric. An aqueous solution of tartaric acid is ppd. by baryta, lime, and lead acetate. Potassium salts, when the solution is not too dilute, form a crystalline pp. of $KC_4H_5O_6$; the formation of the pp. being promoted by rubbing the sides of the vessel with a glass rod and by the addition of alcohol. $CaCl_2$ ppts. CaA'_2 from neutral solutions of tartrates; the ppn. is hindered by ammonium salts. Calcium tartrate dissolves in KOHAq and is re-ppd. in gelatinous form on boiling. Reduces ammoniacal $AgNO_3$, forming a mirror; the solution then contains oxalic acid (Claus, *B.* 8, 950). Tartaric acid prevents the ppn. by alkalis of the oxides of Al, Bi, Ni, Co, Cr, Cu, Fe, Pb, Pt, and Zn, even on boiling (Aubel a. Ramdohr, *A.* 103, 33; Grothe, *J. pr.* 92, 175). 1 mol. acid prevents the ppn. of 1 mol. $Cu(OH)_2$. A solution of tartaric acid, coloured by a drop of K_2CrO_4, gradually becomes colourless (difference from citric acid) (Salzer, *B.* 21, 1910). A saturated solution of potassium bichromate is slowly turned coffee-brown by tartaric (but not by citric) acid (Cailletet, *C. C.* 1879, 14). Boiling alkaline $KMnO_4$ is turned green, and finally brown, by tartaric acid, but only green by citric acid. Decolourises $KMnO_4$ in acid solution. When H_2SO_4 is present, twice as much $KMnO_4$ must be added to produce a permanent red colour as when it is absent, for in the latter case $MnC_4H_4O_6$ is formed (Fleischer, *B.* 5, 350). Tartaric acid gives an odour of burnt sugar when heated till carbonised. A crystal added to conc. H_2SO_4 containing 1 p.c. resorcin gives a red colour on warming (difference from citric and maleic acids) (Mohler, *Bl.* [3] 4, 728).

To detect small quantities of tartaric acid in presence of citric acid. Add about 1 g. citric acid to a 20 p.c. solution of molybdate of ammonia (1 c.c.), then two or three drops of a dilute solution of H_2O_2, and heat for three minutes on the water-bath. If the citric acid is pure the solution remains yellow. If 0·1 p.c. or more of tartaric acid is present, the liquid become blue (Crismer, *Bl.* [3] 6, 23).

Reactions.—1. Melts at 135°, changing to the isomeric metatartaric acid. The metatartaric acid may be reconverted into tartaric acid by boiling with water (Grosjean, *C. J.* 43, 334).—2. At 140°–150° water is eliminated and ditartrylic acid $C_8H_{10}O_{11}$ is formed. On further heating soluble tartaric anhydride (tartrelic acid), and then insoluble tartaric anhydride, are formed. On further heating the products of distillation (from 250 g.) are pyruvic acid (9 g.), pyrotartaric acid (2 g.), formic acid (·4 g.), resins, aldehydes and volatile acids (2 g.), and tarry bodies (3 g.) (P. Liebermann, *B.* 15, 428). 'Dipyrotartracetone' $C_8H_{12}O_2$ (230°), a colourless liquid, with aromatic odour, is among the products of the distillation of tartaric acid. It combines with bromine (Bourgoin, *C. R.* 86, 674).—3. By heating tartaric acid (10 pts.) with water (1 pt.) at 175° it is converted into racemic acid and inactive tartaric acid. At 165° there is a greater yield of the inactive acid (Jungfleisch, *J.* 1872, 515). Heated with more water at 150° it yields CO_2 and pyrotartaric acid (Wedard, *C. C.* 1888, 889).—4. *Potash-fusion* yields acetic and oxalic acids.—5. *Oxidation* by CrO_3, $KMnO_4$, PbO_2 or MnO_2, and H_2SO_4 yields CO_2 and formic acid. The rate of oxidation has been studied by Krutwig (*Z. P. C.* 2, 787). By slow oxidation by HNO_3 tartronic acid may be obtained.—6. Reduced by HI and P to malic and succinic acids.—7. PCl_5 forms chloro-fumaric chloride.—8. $FeSO_4$ at 100° yields iso-arabic acid $C_6H_{10}O_5$, a thick dextrorotatory syrup, $[\alpha]_D = 20°$, yielding the salts $CaA'_2 9aq$, $Ca_2OA'_2 8aq$, PbA'_2, and $Pb_3A'_2O_2$ (Ballo, *B.* 22, 750).—9. *Chloral* forms $C_8H_4Cl_6O_6$ [124°], crystallising from chloroform in small needles, insol. water, sol. warm alcohol and ether (Wallach, *A.* 193, 46).—10. On submitting tartaric acid to *electrolysis* and treating the syrupy mass with phenyl-hydrazine, glyoxal-osazone [160°] and glyoxal-carboxylic osazone [218°] are obtained (Friedel a. Combes, *Bl.* [3] 3, 770).—11. On adding powdered tartaric acid to fused glucose tartaric glucoside is obtained (Guyard, *Bl.* [2] 41, 291; *cf.* Berthelot, *A. Ch.* [3] 54, 78).—12. *m-Amido-benzoic acid* at 160° forms 'tartrylo-dibenzamic' acid $C_{18}H_{16}N_2O_8$ *i.e.* $(CO_2H.C_6H_4.NH.CO)_2C_2H_2(OH)_2$, a colourless powder, insol. water, sol. hot alcohol. Its alkaline salts form yellow solutions in which $Cu(OAc)_2$ ppts. $C_{18}H_{14}(CuOH)_2N_2O_8$. On heating to 190° it yields the anhydride $C_{18}H_{14}N_2O_7$, a greenish-yellow powder, converted by an alcoholic solution of aniline into tartranil dibenzamic acid

$$CO_2H.C_6H_4.N\!\left\langle\begin{array}{l}CO\\CH.CH(OH).CONHPh\end{array}\right.$$

[200°] (Schiff, *A.* 232, 156; *G.* 16, 28). Another product of the action of tartaric acid on *m*-amido-benzoic acid is 'tartryl-benzamic' acid

$$CO_2H.CH(OH).CH(OH).CO.NHC_6H_4.CO_2H,$$

which crystallises from water in pale-yellow aggregates, yields an acetyl derivative and an anhydride 'tartranbenzamic' acid $C_{11}H_9NO_6$, crystallising from water in green plates, forming $C_{11}H_7BaNO_6$ and $C_{11}H_7CuNO_6$, and converted at 210° in 'benzamtartridic' acid by dehydration. A warm alcoholic solution of aniline converts 'tartranbenzamic' acid into 'tartranilbenzamic' acid [245°], which yields an acetyl derivative [198°]. 'Tartryl-benzamic' acid heated with dry amido-benzamide at 140° forms the compound $C_2H_2(OH)_2(CO.NH.C_6H_4.CONH_2)_2$, a white powder, insol. water, sl. sol. alcohol, and yielding $C_{18}H_{15}CuN_3O_7$ aq.—13. *Glycerin* at 100° yields the compounds $C_3H_5(OH)_2.O.C_4H_5O_5$ and $C_3H_5(OH)(OC_4H_5O_5)_2$ (Desplats, *J.* 1859, 500). Glycerin at 140° gives $C_{11}H_{14}O_{12}$ and $C_{15}H_{22}O_{19}$.—14. *Erythrite* at 100° forms $C_{12}H_{18}O_{14}$, which gives $Ca_3(C_{12}H_{15}O_{14})_2 3aq$ (Berthelot, *A. Ch.* [3] 54, 84). 15. *Quercite* at 120° forms $C_{22}H_{32}O_7$, which gives $Ca_4C_{22}H_{26}O_7 2aq$.—16. *Pinite* at 120° forms $C_{30}H_{36}O_{35}$, which gives $Ca_3C_{30}H_{30}O_{35}$.—17. *Mannite* at 120° forms $C_{30}H_{36}O_{35}$, which yields $Mg_7O_4(C_{30}H_{30}O_{35}) 30aq$ and $Ca_3C_{30}H_{30}O_{35} 6aq$.—18. *Dulcite* forms $C_{14}H_{20}O_{15}$, which gives $Ca(C_{14}H_{19}O_{15})_2 4aq$.—19. *Phenyl hydrazine* (2 mols.) at 140° forms $C_{16}H_{18}N_4O_4$ *i.e.* $C_2H_4O_2(CO.N_2H_2Ph)_2$ [226°] (Bülow, *A.* 236, 196); [c. 240°] (Fischer a. Passmore, *B.* 22, 2734), crystallising from alcohol in plates.

Estimation.—Methods for estimating tartaric acid have been described by Scheurer-Kestner, *C. R.* 86, 1024; Berthelot, *Fr.* 3, 216; Vogel a. Braun, *Fr.* 7, 149; Kissel, *Fr.* 8, 409; Fleischer, *Fr.* 12, 328; Oliveri, *G.* 14, 453; Piccard, *Fr.* 21, 424; C. Schmitt a. Hiepe, *Fr.* 21, 539; Amthor, *Fr.* 21, 195; Nessler a. Barth, *Fr.* 21, 60; 22, 159; Kayser, *Fr.* 22, 123; 23, 29; Musset, *Fr.* 24, 279; Ferrari, *Fr.* 24, 279; Warington, *C. J.* 28, 25; Grosjean, *C. J.* 35, 341; Klein, *Fr.* 24, 379; Borntráger, *Fr.* 25, 327; 26, 699; Gantter, *Fr.* 26, 714; Von Lorenz, *Fr.* 27, 8; Philips, *Fr.* 29, 577; Goldenberg, *Fr.* 22, 270; Heidenhain, *Fr.* 27, 681; Weigert, *Fr.* 23, 357; Haas, *C. C.* 1888, 1045; Ward, *Ph.* [3] 19, 380.

Salts (Berzelius, *P.* 19, 305; 36, 4; *A. Ch.* [2] 67, 303; Werther, *J. pr.* 32, 383; Dumas a. Piria, *A. Ch.* [3] 5, 353; De la Provostaye, *A. Ch.* [3] 3, 129).—$(NH_4)_2A''$. $[\alpha]_D = 33\cdot7°$ in a 1·2 p.c. solution (Sonnenthal, *M.* 12, 603). Efflorescent monoclinic prisms, v. sol. water; $a:b:c = \cdot868:1:1\cdot244$ $\alpha = 88° 9'$. Give off NH_3 in air. Yield succinic acid on fermentation (Koenig, *G.* 11, 180).—$(NH_4)HA''$. $[\alpha]_D = 25\cdot7°$ (Landolt). Minute laminæ, sl. sol. cold water. Forms with ammonium malate $(NH_4)HA''(NH_4)C_4H_5O_5$, crystallising in prisms, S. 9 (Pasteur, *J.* 1853, 415).—$K_2A''\frac{1}{2}aq$. $[\alpha]_D = 25\cdot5°$ in a 2 p.c. solution. S. 133 at 2°; 158 at 23° (Osann). V. sl. sol. hot alcohol. Monoclinic crystals; $a:b:c = \cdot402:1:1\cdot109$; $\alpha = 75° 12'$.—KHA''. *Cream of tartar.* $[\alpha]_D = 22°$ in a ·4 p.c. solution. 100 g. solution contain $\cdot369 + \cdot000569t^2$ grammes at $t°$ (Blarez, *C. R.* 112, 434, 808). S. ·25 at 0°; ·4 at 10°; ·55 at 20°; 1·13 at 40° (Chancel, *C. R.* 60, 408; *cf.* Alluard, *C. R.* 59, 500). Obtained by crystallisation of argol, which is deposited during vinous fermentation. Trimetric crystals; $a:b:c = \cdot712:1:\cdot787$. Insol. alcohol.—$Na_2A'' 2aq$. $[\alpha]_D = 31°$ in a 1 p.c. solution (Sonnenthal; *cf.* Thomsen, *J. pr.* [2] 34, 80; 35, 145). S. 29 at 6°; 44 at 24°; 66 at 42·5° (Osann). Trimetric prisms; $a:b:c = \cdot770:1:\cdot387$. V. sol. hot water, insol. alcohol.—NaHA''. $[\alpha]_D = 24\cdot3°$ in a 1·3 p.c. solution (S.).—NaHA''aq (Dumas a. Piria, *A.* 44, 80). S. 11 in the cold; 55 at 100°. Minute crystals, with hemihedral facets. Insol. alcohol.—Li_2A''. $[\alpha]_D = 37\cdot5°$ in a ·7 p.c. solution (S.). Deliquescent.—LiHA'' 1½aq. Small crystals, v. sol. water (Dulk, *Schw. J.* 64, 180, 193; *A.* 2, 47).—LiHA''aq.—$Li_4H_2A''_4TeO$ 2aq. Needles (Klein, *A. Ch.* [6] 10, 118; *C. R.* 102, 47). — **Hydroxylamine salt** $(NH_4O)_2A''$. Very thin plates (Lossen, *A. Suppl.* 6, 233).—NH_4NaA'' 4aq. Trimetric crystals, with hemihedral facets, isomorphous with KNaA'' 4aq; *a:b:c* = ·823:1:·420. $[\alpha]_j = 26°$. $[\alpha]_D = 32·7°$ (Landolt). V. sol. water. $[\alpha]_D = 31°$ (L.).—KLiA''aq.—KNaA'' 4aq. *Rochelle salt.* S. 30 at 3°, 66 at 26° (Osann). Heat of solution −6290 at 15°. The heat of solution of KNaA'' is −2989 (Pickering, *C. J.* 51, 351). Large trimetric prisms, with hemihedral facets. Melts at 70°–80° in its water of crystallisation, and becomes anhydrous at 215° (Fresenius, *A.* 53, 234). $[\alpha]_D = 29·7°$ (L.). *Molecular rotation*: Long, *Am. S.* 36, 351.—$K_2A''_2TeO$ (dried at 100°).—RbHA''. Trimetric prisms, isomorphous with the cæsium salt; *a:b:c* = ·726:1:·695 (J. P. Cooke, *Am. S.* [2] 37, 70). S. 1·18 at 25°; 11·7 at 100° (Allen, *Am. S.* [2] 34, 367).—NaRbA'' 4aq. Isomorphous with Rochelle salt (Piccard, *J.* 1862, 125).—Cs_2A''. Trimetric prisms. S. 10 at 25°; 100 at 100°.—Tl_2A'' ½aq. $[\alpha] = 4·8°$ in a 5 p.c. solution at 20°. Sl. sol. water and alcohol.—TlHA''. $[\alpha] = 12°$ in a 1 p.c. solution at 20°. Small flat prisms (De la Provostaye, *A. Ch.* [3] 3, 129; Kuhlmann, *J.* 1862, 188).—TlNaA'' 4aq. At 20° $[\alpha] = 0°$ in a 5 p.c. solution and 6·5° in a 20 p.c. solution.—TlLiA''aq. $[\alpha] = 9·5°$ in a 5 p.c. solution at 20°.—TlKA''. $[\alpha] = 10°$ in a 5 p.c. solution at 20°.—$Tl(NH_4)A''$. $[\alpha] = 10°$ in a 5 p.c. solution at 20°.—BaA''. White amorphous pp., becoming crystalline. S.G. $\frac{21·4}{4}$ 2·973 (Clarke, *Am.* 2, 174).—BaA''aq (Dulk). S. (amorphous) 1·2; (crystalline) ·077 (Vogel a. Reischauer, *J.* 1859, 288). $K_2BaA''_2$ 2aq. Powder, sl. sol. water.—$Na_2BaA''_2$ 2aq. Needles, sl. sol. water, more soluble in a solution of Rochelle salt. Ppd. on mixing a solution of Rochelle salt with $BaCl_2$.—BaA''TeO (dried at 100°).—SrA'' 4aq. Monoclinic prisms. S. ·7 at 16°. S.G. $\frac{19·8}{4}$ 1·966 (Clarke).—SrA'' 3aq (Marignac, *Ann. M.* [5] 15, 280).—$(NH_4)_2SrA''_2$ 12aq. Thin plates.—K_2SrA'' 2aq.—Na_2SrA'' *x*aq.—$CaH_2A''_2$. S. ·71 at 15·6°. Trimetric crystals.—CaA'' 4aq. Occurs in grapes. Ppd. as white crystalline powder on adding $CaCl_2$ to a solution of K_2A''. Small trimetric prisms. *a:b:c* = ·872:1:·908 (Anschütz, *A.* 226, 191). S. ·016 at 15°: ·3 at 100° (Mohr, *J.* 1865, 393). Forms, with calcium malate, the double salt $CaA''CaC_4H_4O_5$ 6aq, crystallising in needles, S. 1·25 at 17° (Ordonneau, *Bl.* [3] 6, 262).—MgA'' 4aq. S. ·8 at 16°. $[\alpha]_D = 36°$.—$Mg_2C_4H_2O_6$ 3aq. S. ·024. Ppd. by adding NH_3 to a solution of MgA'' (Mayer, *A.* 101, 166).—$MgNa_2A''_2$ 10aq.—MgK_2A'' 8aq.—$MgH_2A''_2$. S. 2 at 16°.—BeA'' 3aq (Atterberg, *Bl.* [2] 21, 162).—$BeK_2C_4H_2O_6$ 3aq. Prisms (Toczynski, *Z.* 1871, 277).—K(SbO)A'' ½aq. *Tartar emetic.* Prepared by boiling Sb_2O_3 (3 pts.) with cream of tartar (4 pts.) and water. Octahedra; *a:b:c* = ·956:1:1·054. $[\alpha] = 141°$ in a 4 p.c. solution at 20°. S.G. 2·6. Efflorescent. At 200° it becomes $K(SbO)C_4H_2O_6$. S. 5 at 8°; 8 at 21°; 52 at 100°. ·05 to ·1g. produce vomiting. Its solution reddens litmus, and gives a crystalline pp. of K(SbO)A'' with alcohol. Its solution is ppd. by mineral acids, by alkalis, and by H_2S. $HgCl_2$ is reduced by it to calomel. Heat of formation: Guntz, *C. R.* 104, 699. Volumetric estimation of Sb in tartar emetic (Dunstan a. Boole, *Ph.* [3] 19, 385). — $K(SbO)A''H_2A''$ 2½aq. Efflorescent prisms. Alcohol added to its aqueous solution ppts. tartar-emetic, leaving tartaric acid in solution (Knapp, *A.* 32, 76).—K(SbO)A''3KHA''. Mammellated groups of needles, v. sol. water.—$(K(SbO)A'')_2NaNO_3$ (Martenson, *J.* 1869, 539).—Na(SbO)A'' ½aq. Trimetric, hygroscopic prisms; *a:b:c* = ·922:1:1·08. — $(Na_2A'')_3 2Sb(OH)_3$ 3aq. Amorphous, v. sol. water (Clarke a. Evans, *B.* 16, 2385). — $NH_4(SbO)A''$ ½aq. — $NH_4(SbO)A''$ 2½aq (Berlin, *A.* 64, 359).—Rb(SbO)A'' ½aq. Isomorphous with tartar-emetic (Grandeau, *A. Ch.* [3] 67, 155).—$Tl(SbO)C_4H_4O_6$ aq. $[\alpha] = 100°$ in a 2 p.c. solution at 20° (Long, *Am. S.* [3] 38, 264).—Ag(SbO)A'' ½aq. Crystals (J. P. Cooke, *Am. S.* [3] 19, 393).—$Ba(SbOA'')_2$ 2½aq.—Cd(SbOA'') 2aq. Converted at 200° into $Cd(SbOC_4H_2O_5)_2$ (Schiff, *A.* 104, 328). — $(Ca(SbOA'')_2)_4Ca(NO_3)_2$ 24aq. Crystallises from a solution of tartar-emetic mixed with calcium nitrate in trimetric forms (Marignac, *Ann. M.* [5] 15, 280).—$Sr(SbOA'')_2$. Hexagonal crystals. — $Sr_2(SbOA'')_2(NO_3)_2$ 12aq. Very soluble crystals (Kessler, *P.* 75, 410).—$Pb(SbOA'')_2$ 4aq. — $Ba_3Sb_2(C_4H_2O_6)_3$. — $Sb(HA'')_3$ 4aq. Needles, v. sol. water (C. a. E.).—$Sb_2A''_3$ 6aq.—(SbO)HA''aq (Clarke a. Stallo, *B.* 13, 1788).—(SbO)HA'' (Guntz, *C. R.* 104, 850).—$C_4H_4O_5Sb_2O_3$aq. White granular pp., formed by adding alcohol to a solution of Sb_2O_3 in aqueous tartaric acid (Berzelius). Converted by heat into $SbOC_4H_2O_5$.—$(C_4H_3O_{11})_4Sb_2O_3$ 6aq (Péligot, *A. Ch.* [3] 20, 289).—$(C_4H_3O_{4½})_2Sb_2O_3$ (dried) (P.). — $(C_4H_4O_5)_2Sb_2O_3H_2O$. Crystals (Guntz, *A. Ch.* [6] 13, 396).—**Berberine salt** $C_{20}H_{18}NO_4(SbO)A''$ (Stenhouse, *J.* 1863, 452).—**Brucine salt** $C_{23}H_{27}N_2O(SbO)A''$.—**Quinine salt** $C_{20}H_{25}N_2O_2(SbO)A''$ (Clarke, *B.* 15, 1540).—**Atropine salt** $C_{17}H_{24}NO_3(SbO)A''$ 2aq.—**Aniline salt** $C_6H_7N(SbO)A''$. Long white prisms. S.G. 1·89 at 11°.—$NH_4(AsO)A''$ ½aq. Large efflorescent trimetric crystals; *a:b:c* = ·876:1:·694. Got by dissolving As_2O_3 in NH_4HA'' (Mitscherlich; Werther, *J. pr.* 32, 409).—$K(AsO_2)A''$ 2½aq. Got by dissolving arsenic acid in a solution of cream of tartar (Pelouze, *A. Ch.* [3] 6, 68).—$(Sr(AsOA'')_2)_2NH_4NO_3$ 12aq. Large trimetric crystals (Marignac).—$Bi_2A''_3$ 6aq. Small crystals, decomposed by water (Schneider, *P.* 88, 55).—$K(BiO)C_4H_2O_6$ (Schwarzenberg, *A.* 61, 244).—$Bi_2K(BiO)(C_4H_2C_6)_2$ (Frisch, *J.* 1866, 401).—K(BO)A'' (dried at 100°). *Potassium borotartrate.* Amorphous mass, v. sol. water, insol. alcohol. At 100° it becomes $K(BO)C_4H_2O_5$. Purgative. $[\alpha] = 58°$ in a 20 p.c. solution at 20°.—$K_2(BO)C_4H_3O_6$.—$K_2(BO)_2C_4H_2O_6$.—Na(BO)A''.—$Na_2(BO)C_4H_3O_6$.—$Na_2(BO)_2C_4H_2O_6$ (Duve, *J.* 1869, 540). — $K_2(BO)_2C_4H_2O_6Na(BO)A''$. — $Ba(BO)C_4H_3O_6$.—$Ba(BO)_2C_4H_2O_6$.—PbA''. S.G. $\frac{17·2}{4}$ 4·012 (Clarke, *Am.* 2, 174). White crystalline pp., v. sol. HNO_3.—$Pb_2C_4H_2O_6$ aq (Erdmann, *A.* 21, 14). Insol. water, v. sol. KOHAq. — $Pb_3(C_4H_3O_6)_2$. — $Ce_2A''_3$ 9aq (?). — $Th_2K_2A''_3$. — CuA'' 3aq. S. ·06 in the cold; ·3 at 100°. Light-green powder.—$CuA''4NH_3$ (Schiff, *A.* 123, 46).—$(H(NH_4)A'')_2(HgO)_3 3H_2O$ (Harff, *Brandes' Arch.* 5, 259; Burckhardt, *ibid.* [2] 11, 257).—$(KHA'')_4HgCl_2 6aq$.—$K_2NiA''_2$ (dried at 110°). Efflorescent, apple-green crystalline powder (Fabian, *A.* 103, 248).—$CoCl(HA'')_2 5NH_3 2\frac{1}{2}aq$ (Jörgensen, *J. pr.* [2] 18, 239).—$ZnA''2aq$ (Schiff, *A.* 125, 146).—$Zn_2C_4H_2O_6 \frac{1}{2}aq$. Powder, insol. water.—$Cr(OH)A''$. Violet flakes, turning dark-blue over H_2SO_4 (Schiff, *A.* 125, 145). At 220° it yields $CrC_4H_3O_6$.—$K(CrO)A'' 3\frac{1}{2}aq$ (Malaguti, *C. R.* 16, 457).—$(UrO_2)A'' 3aq$ (Péligot, *A.* 56, 231).—$K_2(UrO_2)A''_2$ (dried at 200°).—$(SbO)_2(UrO_2)A''_2 8aq$.—SnA''. Minute crystals.—$K(FeO)A''4$ or 5aq. Prepared by digesting cream of tartar with water and $Fe(OH)_3$. Brown scales, red by transmitted light. Acids ppt. from its solutions a basic salt, sol. excess.—$NH_4(FeO)A''4$ (or 5) aq.—$Fe_2A''_3$.—FeA''. Formed by boiling tartaric acid with water and iron wire (Méhu, *N. J. P.* 40, 257). Minute crystalline powder. S. ·877 at 15·6° (Dulk, *A.* 2, 62).—$K(MnO)A''4aq$ (Descamps, *Z.* 1870, 317).—Ag_2A''. Amorphous curdy pp. got by adding $AgNO_3$ to a cold solution of Rochelle salt. Crystallises from a warm solution in white scales. Nearly insol. water. Its ammoniacal solution deposits Ag on warming (Liebig a. Redtenbacher, *A.* 38, 132; Erdmann, *J. pr.* 25, 504).—$AgHA''$ (Perkin, *C. J.* 51, 369). Monoclinic tables.

Ethylene-diamine salt $C_4H_4O_6(N_2H_6C_2H_4)$. Dextrorotatory. Leaflets, v. sol. water. The acid salt is sl. sol. water, S. 8 at 15°, and the solution is dextrorotatory (Colson, *Bl.* [3] 7, 808).

Mono-methyl ether $MeHA''$. Formed by boiling tartaric acid with MeOH (Guérin, *A.* 22, 248). Prisms.—$KMeA''$.—$BaMe_2A''_2 aq$ (Dumas a. Péligot, *A. Ch.* [2] 61, 200; [3] 5, 373).

Di-methyl ether Me_2A''. [48°]. (280° i.V.). S.G. (liquid) $\frac{15}{}$ 1·340. $[\alpha]_D = 2{\cdot}454$ at 18° (Anschütz a. Pictet, *B.* 13, 1176; 18, 1399); $= 2{\cdot}14$ (Phillips a. Guye, *C. R.* 110, 714). Yields an acetyl derivative [103°] $[\alpha]_D = -14°$ and a dibenzoyl derivative $[\alpha]_D = -88{\cdot}8°$.

Mono-ethyl ether $EtHA''$. [90°]. Formed by dissolving tartaric acid in boiling alcohol (G.; Marian, *N. J. T.* 13, 2, 43; Trommsdorff, *N. J. T.* 24, 1, 11; Guérin, *A. Ch.* [2] 62, 57). Very deliquescent prisms.—$NaEtA''$. Powder, sl. sol. alcohol (Mulder, *B.* 8, 370).—$KEtA''$. S. 106° at 23·5°. Colourless trimetric prisms; $a:b:c = {\cdot}288:1:{\cdot}417$.—$Ca(EtA'')_2 5aq$.—$Ba(EtA'')_2 2aq$. S. 38 at 23°; 128 at 100°.—$Pb(EtA'')_2$.—$Cu(EtA'')_2 6aq$. Blue silky efflorescent needles.—$AgHA''$. Prisms.

Di-ethyl ether Et_2A''. (280° i.V.); (233° cor. at 197 mm.). S.G. $\frac{15}{15}$ 1·2097; $\frac{25}{25}$ 1·2019. $[\alpha]_D = 9$ at 18° (Anschütz a. Pictet, *B.* 13, 1176); 7·22 at 12°; 8·02 at 20° (Perkin, *C. J.* 51, 863). M.M. 8·766 at 14·8°. Liquid miscible with water (Demondesir, *A.* 80, 301). Sodium forms $CO_2Et.CH(ONa).CH(OH).CO_2Et$ and $CO_2Et.CH(ONa).CH(ONa).CO_2Et$, the latter being converted by EtCl into a deposit and a liquid, part of which is soluble in alcohol and ether and part insoluble in alcohol and ether (Mulder, *R. T. C.* 8, 375; 9, 238; 10, 171; *cf.* Cohn, *B.* 20, 2003). The soluble product mixed with alcoholic $CuCl_2$ and poured into water forms a pp. crystallising in light-green needles, sol. alcohol and ether, insol. water and $CuC_{16}H_{24}O_{11}$. Tartaric ether is converted by treatment with gaseous HCyO into allophanyl-tartaric ether $NH_2.CO.NH.CO.O(C_4H_3Et_2O_5)$ [188°], which is m. sol. hot water and alcohol.

Acetyl derivative of the ether $CO_2Et.CH(OAc).CH(OH).CO_2Et$. Formed from the ether and AcCl, the mixture becoming hot (Perkin, *C. J.* 20, 145). Heavy oil, sl. sol. water, insol. saline solutions. Neutral to litmus.

Di-acetyl derivative of the ether $CO_2Et.CH(OAc).CH(OAc).CO_2Et$. [67°]. (292°) (Pictet, *B.* 14, 2790); (230° at 100 mm.). Formed by heating tartaric ether with AcCl at 100° (Perkin; Wislicenus, *A.* 129, 187). Prisms (from water), v. sl. sol. water. Slowly saponified by KOHAq.

Acetyl-benzoyl derivative of the ether $CO_2Et.CH(OAc).CH(OBz).CO_2Et$. Formed by heating the mono-benzoyl derivative of the ether with AcCl at 150° (Perkin). Heavy oil.

Mono-benzoyl derivative of the ether $CO_2Et.CH(OH).CH(OBz).CO_2Et$. [64°]. Formed by heating the ether with BzCl at 100°. Prisms, sl. sol. hot Aq. Saponified by alcoholic potash yielding $C_2H_2(OH)(OBz)(CO_2Et).CO_2K$, $C_2H_2(OH)(OBz)(CO_2K)_2$, and finally, potassium tartrate. $C_2H_2(OH)(OBz)(CO_2Et).CO_2H$ forms tufts of needles, sl. sol. water.

Di-benzoyl derivative of the ether $[\alpha]_D = -60°$ (Phillips a. Guye, *C. R.* 110, 716).

Di-n-propyl ether Pr_2A''. (303° i.V.). S.G. $\frac{17}{}$ 1·1392. $[\alpha]_D = 13{\cdot}77$ at 18° (A. a. P.); $= 12{\cdot}44$ (P. a. G.).

Di-isopropyl ether Pr_2A''. (275°). S.G. $\frac{20}{}$ 1·130. $[\alpha]_D = 14{\cdot}89$ at 20° (Pictet, *J.* 1882, 856). Liquid.

Di-isobutyl ether $(Pr.CH_2)_2A''$. [68°]. (324°). S.G. $\frac{100}{}$ 1·015. $[\alpha]_D = 19{\cdot}9°$ (P.). Yields a dibenzoyl derivative $[\alpha]_D = -42°$.

Isoamyl ether $(C_5H_{11})HA''$. Formed by digesting tartaric acid (150 pts.) with isoamyl alcohol (88 pts.) at 130° (Balard, *A. Ch.* [3] 12, 309; Breunlin, *A.* 91, 314). Nodular mass, with very bitter taste.—$KC_5H_{11}A'' aq$. Crystalline.—$NaC_5H_{11}A''$. Nodules.—$Ba(C_5H_{11}A'')_2 2aq$: pearly plates (from water).—$Pb(C_5H_{11}A'')_2$.—$Ca(C_5H_{11}A'')_2$.—$AgC_5H_{11}A''$. Tufts of needles.

Di-acetyl derivative $C_8H_{10}O_8$ *i.e.* $CO_2H.CH(OAc).CH(OAc).CO_2H$. $[\alpha]_D = -23{\cdot}14$ (Phillips a. Guye, *C. R.* 110, 716). Formed slowly from the anhydride by the action of water. Hard deliquescent crystals (containing 3aq), melting at 58°. V. sol. water, alcohol, and ether, sl. sol. benzene. Lævorotatory. Its salts form lævorotatory solutions (Colson, *Bl.* [3] 7, 806; *C. R.* 114, 417). Converted into tartaric acid by hot KOHAq.—KHA'': crystalline powder.—BaA'': slender deliquescent needles.—CaA''.—CuA''.—Ag_2A'': white crystalline mass.—Ethylene-diamine salt $C_8H_8O_8(N_2H_6C_2H_4)$. Lævorotatory. V. sol. water.

Anhydride of the di-acetyl derivative $C_8H_8O_7$. [127°]. Formed by heating tartaric acid with AcCl (Ballik, *Sitz. W.* 29, 26; Pilz, *Sitz. W.* 44 [2] 7; Perkin, *C. J.* 20, 149). Slender needles (from benzene). Dextrorotatory.

Benzoyl derivative $C_{11}H_{10}O_7$ *i.e.* $CO_2H.CH(OH).CH(OBz).CO_2H$. Formed by heating tartaric acid with benzoic acid at 150°

(Dessaignes, *J. Ph.* [3] 32, 47). Minute crystals, v. sol. water, sl. sol. alcohol.—Ag_2A'': white pp.

Di-benzoyl derivative $C_{18}H_{14}O_8$ *i.e.* $CO_2H.CH(OBz).CH(OBz).CO_2H$. [90°]. $[\alpha]_D = -116°$ in alcohol. Formed by dissolving its anhydride in hot water. Needles (containing aq). Converted by heat into a crystalline substance melting at 132°.

Anhydride $C_{18}H_{12}O_7$. [174°]. $[\alpha]_D = 143°$ in acetone at 18°. Formed by heating tartaric acid with BzCl. Small needles, insol. cold water, sol. alcohol, benzene, and alkalis. Dextrorotatory.

Di-nitroxyl- derivative $CO_2H.CH(NO_3).CH(NO_3).CO_2H$. *Nitrotartaric acid.* Formed by dissolving tartaric acid (1 pt.) in HNO_3 (4½ pts.), and stirring with an equal volume of H_2SO_4 (Dessaignes, *A.* 82, 362; 89, 339). The crystals are dried and crystallised from ether (Kekulé, *A.* 221, 245). Silky prisms, decomposed by hot water, forming oxalic and tartronic acids, CO_2, and NO. Alcohol containing HNO_2 forms di-oxy-tartaric acid. Ammonium sulphide reduces it to tartaric acid.—$(NH_4)HA''$.—Ag_2A'' aq. V. sol. water.—Et_2A''. [46°]. S.G. $\frac{15}{}$ 1·278. Formed by dissolving tartaric ether in a mixture of HNO_3 and H_2SO_4 and ppg. with water.

Amide $C_2H_4O_2(CO.NH_2)_2$. Formed by passing NH_3 into an alcoholic solution of the ether, or of its di-acetyl derivative (Demondesir, *A.* 80, 303; Pasteur, *C. R.* 35, 176; Grote, *A.* 130, 202; Ruhemann, *B.* 20, 3366). Trimetric crystals (from water), v. e. sol. water. Dextrorotatory.

Amic acid $C_4H_7NO_5$ *i.e.* $CO_2H.CH(OH).CH(OH).CO.NH_2$. Formed by passing NH_3 over tartaric anhydride moistened with alcohol (Laurent, *Compt. Chim.* 1845, 153). Formed also, together with tartaric acid, by heating tartaric ether with NH_3Aq at 100° (Grote). Syrup.—CaA'_2 6aq: tetrahedra, v. sol. water.—$Pb_3(C_4H_4NO_5)_2$.—BaA'_2 8aq.—EtA′.

Anilide $C_2H_4O_2(CO.NHPh)_2$. [250°]. Formed by boiling aniline with tartaric acid (Polikier, *B.* 24, 2959). Pearly scales, insol. water, sl. sol. other solvents. Yields mono-, di-, and tri-acetyl derivatives, melting at 227°, 216°, and 137° respectively.

Phenyl-amic acid $C_{10}H_{11}NO_5$ *i.e.* $CO_2H.CH(OH).CH(OH).CO.NHPh$. [180°]. Formed by boiling the phenylimide with NH_3Aq (Arppe, *A.* 93, 352). Plates, v. sol. water and alcohol.—BaA'_2: spangles, m. sol. hot water.—AgA′: white powder, v. sl. sol. water.

Phenylimide $C_{10}H_9NO_4$ *i.e.*

$\begin{array}{l}CH(OH).CO\\CH(OH).CO\end{array}\!\!>\!NPh$. [230°]. Formed, together with the anilide, by heating tartaric acid with aniline at 150°. Pearly plates, v. sol. water.

Di-o-toluide $C_2H_4O_2(CO.NH.C_6H_4Me)_2$. [183°]. White plates, insol. water (Bischoff, *B.* 23, 2049). Ac_2O at 140° yields a di-acetyl compound [222°].

Di-p-toluide $C_2H_4O_2(CO.NH.C_6H_4Me)_2$. [264°]. Got by heating *p*-toluidine with tartaric acid at 185°. Silky needles (from alcohol). Converted by Ac_2O into a di-acetyl derivative [202°].

Hydrazide $C_2H_2(OH)_2(CO.NH.NH_2)_2$. [183°]. Formed from tartaric ether and hydrazine hydrate (Von Rothenburg, *B.* 26, 2057). Needles, sl. sol. alcohol. Converted by benzoic aldehyde into $C_2H_2(OH)_2(CO.N_2H:CHPh)_2$ [225°], crystallising in yellowish plates (from alcohol).

Lævo- tartaric acid

$CO_2H.CH(OH).CH(OH).CO_2H$. *Anti-tartaric acid.* [170°]. When a solution of racemic acid is divided into two equal parts and one is neutralised by ammonia and the other by soda, and the solutions mixed and allowed to evaporate, hemihedral crystals of $Na(NH_4)C_4H_4O_6$ are obtained. Half of these crystals have the hemihedral faces oppositely situated to those of the other half; and on carefully selecting the two kinds of crystals (the solutions of which exhibit equal and opposite action on polarised light), ppg. their solutions by lead nitrate, and decomposing the lead salts by H_2S or H_2SO_4, solutions are obtained which on evaporation yield crystals, the one of dextro- and the other of lævo- tartaric acid (Pasteur, *A. Ch.* [3] 28, 56). If in a solution of sodium ammonium racemate of S.G. 1·26 a crystal of the dextro- salt be put on one side and one of the lævo- salt be put on the other side of the vessel, the two salts will crystallise separately (Jungfleisch, *J. Ph.* [5] 5, 346). The separation of sodium ammonium racemate into the dextro- and lævo- tartrates does not take place if the solution is heated to 118° in a sealed tube and allowed to crystallise without access of air (Bichat, *Bl.* [2] 46, 54). According to Wyrouboff (*C. R.* 102, 627), the splitting up of the sodium ammonium racemate depends upon strength of solution and temperature only.

Lævo-tartaric acid is exactly like dextro tartaric acid in solubility and S.G. Its crystals are like the reflection of those of the dextro-acid. The two acids are oppositely pyro-electric. Solutions of the lævo- acid exhibit an effect on light equal and opposite to that produced by solutions of the dextro- acid of like strength. When conc. solutions of equal quantities of the dextro- and lævo- acids are mixed, heat is given out and racemic acid separates. The salts of the lævo-tartaric acid have the same amount of water of crystallisation, and the same crystalline form as the salts of dextro-tartaric acid. They exhibit opposite hemihedry, opposite rotation, and are oppositely pyro-electric. Differences are observed between the compounds of the two acids with optically active substances. Acid ammonium (active) malate combines with acid ammonium dextro- (but not lævo-) tartrate. Cinchonine lævo- tartrate $C_{19}H_{22}N_2OC_4H_6O_6$ contains aq, while the dextro-tartrate contains 4aq.

Di-methyl-ether Me_2A''. [48°]. (160° at 16 mm.). Lævorotatory (Anschütz, *B.* 18, 1398; *A.* 247, 112).

Di-acetyl derivative of the di-methyl ether $CO_2Me.CH(OAc).CH(OAc).CO_2Me$. [103°]. $[\alpha]_D = -1·3$ (in a 3·6 p.c. solution in alcohol of S.G. ·826). Formed by heating Me_2A'' with AcCl. Monoclinic plates (from benzene); $a:b:c = 1·052:1:1·007$; $\beta = 87° 54'$. On mixing with the corresponding dextro- compound it forms the isomeric racemic compound [86°].

Amide $C_4H_4O_4(NH_2)_2$. Combines with the amide of active malic acid, forming needles, S. more than 33.

Racemic acid $C_4H_6O_6$. *Paratartaric acid.* [206°] (Bischoff, *B.* 22, 1812). S.G. (of H_2A'') = 1·778; (of H_2A'' aq) 1·687 (Perkin, *C. J.* 51, 366). S. (of H_2A'') 8·16 at 0°; 18 at 20°; 137·8 at 100°. S. (of H_2A'' aq) 9·23 at 0°; 20·6 at 20°; 184·9 at 100° (Liedie, *C. R.* 95, 87). Heat of solution at 9°: −5675 (for H_2A''); −7065 (for H_2A'' aq) (Pickering, *C. J.* 51, 367). H.C. (for H_2A'') 1,851,190 (Ossipoff, *C. R.* 108, 1105). H.F. (for H_2A'' aq) 278,400. Acid potassium racemate either occurs sometimes in crude argol, or is produced therefrom in the purification processes (Kestner; Jungfleisch, *C. R.* 85, 805). On crystallisation of cream of tartar, acid potassium racemate remains in the mother-liquor.

Constitution.—Assuming racemic acid to be a compound of the dextro- and lævo-tartaric acids, its formula must be at least $(C_4H_6O_6)_2$.

Formation.—1. By mixing solutions of dextro- and lævo- tartaric acids.—2. By heating tartaric acid (30 g.) with water (4 c.c.) for 30 hours at 175° (Jungfleisch, *Bl.* [2] 18, 203).—3. By heating the dextro- or lævo- tartrate of quinine or cinchonine at 170° (Pasteur, *A.* 72, 164; 84, 157; 88, 211).—4. By heating tartaric ether.—5. By heating inactive tartaric acid at 200° or by boiling it with HClAq (Dessaignes, *Bl.* 1865, i. 34).—6. By oxidation of fumaric acid by aqueous $KMnO_4$ (Kekulé a. Anschütz, *B.* 13, 2150; *A.* 226, 191; *cf.* Tanatar, *B.* 12, 2293). 7. By the action of HNO_3 on lævulose, mucic acid, and inulin; and, together with tartaric acid, by the action of HNO_3 on milk sugar, cane sugar, saccharic acid, dulcite, and mannite (Carlet, *Rép. Chim. pure*, 2, 345; 4, 17; Hornemann, *J. pr.* 89, 283).—8. Together with inactive tartaric acid by boiling silver di-bromo-succinate with water (Perkin a. Duppa, *C. J.* 13, 102; Pasteur, *A. Suppl.* 2, 242; Jungfleisch, *Bl.* [2] 19, 198).—9. By boiling silver iso-di-bromo-succinate with water (Demuth a. Meyer, *B.* 21, 268). 10. By boiling glyoxal with dilute HCy and HCl (Schöyen, *A.* 132, 168; Strecker, *Z.* [2] 4, 216).—11. By the action of zinc-dust (2 mols.) and dilute HOAc (3 mols.) on glyoxylic acid (1 mol.) at 100° (Genviesse, *Bl.* [3] 7, 225; *C. R.* 114, 555).—12. From piperic acid, sorbic acid, and $CHO.CH{:}CH.CH{:}CH.CO_2H$ by careful oxidation with dilute $KMnO_4$ below 4° (Doebner, *B.* 23, 2374).—13. By heating a solution of desoxalic acid (Löwig, *J.* 1861, 605; Klein, *J. pr.* [2] 20, 157).

Preparation.—Sodium ammonium racemate, got from the mother-liquor from which cream of tartar has separated, is treated exactly in the same way as cream of tartar in the preparation of tartaric acid. The small opaque needles of racemic acid can be separated by handpicking from the large transparent crystals of tartaric acid.

Properties.—Triclinic crystals (containing aq); $a{:}b{:}c = {·}484{:}1{:}{·}806$; $\alpha = 120°$; $\beta = 96°\ 19'$; $\gamma = 76°\ 5'$ (De la Provostaye, *A. Ch.* [3] 3, 131). Slightly efflorescent. Gives off aq at 100°. Less soluble than tartaric acid. In dilute solutions of racemic acid the lowering of the freezing-point is the same as with an equal weight of tartaric acid (Raoult, *Z. Ph.* 2, 186). Absorption of a solution of racemic acid by filter paper does not separate the dextro- and lævo- acids (Marchlewski, *B.* 26, 983). A solution of racemic acid is ppd. by $CaSO_4$ (unlike tartaric acid). Calcium racemate is insol. acetic acid (unlike calcium tartrate). NH_4Cl does not hinder the ppn. of calcium racemate. When heated above 200° racemic acid yields the same products as tartaric acid. By various ferments (*e.g. Penicillium glaucum*) racemic acid, when free or as acid ammonium salt, is converted into tartaric acid (Pasteur; *cf.* E. Mulder, *R. T. C.* 1, 231). A solution in HNO_3 (S.G. 1·52) poured into half its volume of H_2SO_4 deposits the crystalline $C_2H_2(O.NO_2)_2(CO_2H)_2$ (Dessaignes, *J. Ph.* [3] 32, 46). AcCl converts racemic acid into di-acetyl-racemic anhydride $C_2H_2(OAc)_2C_2O_3$ [123°]. Racemic acid and its salts are inactive to light.

Salts (Fresenius, *A.* 41, 1; 53, 230).—$(NH_4)_2A''$. Trimetric prisms; $a{:}b{:}c = {·}509{:}1{:}{·}847$. V. sol. water, nearly insol. alcohol. Give off NH_3 in air.—$(NH_4)HA''$. S. 1 at 20°; less sol. boiling water. Monoclinic prisms. Reddens litmus.—K_2A'' 2aq. Six-sided tables. S. 103 at 25°. Nearly insol. alcohol.—KHA''. S. ·55 at 19°; ·7 at 100°. Insol. alcohol.—$K(NH_4)A''$. Striated prisms.—Na_2A''. S. 38 at 25°. Trimetric prisms. Insol. alcohol.—$NaHA''$aq. S. 9 at 19°. Monoclinic prisms (from water). Ppd. from aqueous solution by addition of alcohol.—$Na(NH_4)A''$aq. S.G. 1·746 (Wyruboff, *A. Ch.* [6] 9, 229).—$NaKA''$4aq. S. 47 at 6° (Fresenius, *A.* 53, 230).—$NaKA''$3aq. Monoclinic crystals (Wyruboff, *A. Ch.* [6] 9, 232).—RbA''.—CaA''4aq. Acicular prisms (Anschütz, *A.* 226, 191).—BaA'' 2½aq. S. ·05. Crystalline pp.—SrA''4aq. —TlA'' (De la Provostaye, *A.* 126, 79).—$LiTlA''$2aq (Wyruboff).—$NaTlA''$2aq. S. 25 at 25°.—MgA''5aq. S. ·85 at 19°.—CdA'' (Schiff, *A.* 104, 326).—PbA'' (dried at 100°).—$Pb_2C_4H_2O_6$ (Krug, *J.* 1861, 367).—CuA''2aq. Pale-blue needles, sol. alkalis and solution of Na_2CO_3.—$Na_2CuC_4H_2O_6$ 4aq.—MnA''aq.—NiA''5aq.—$NH_4(AsO)A''$½aq. S. 9·4 at 15°. Efflorescent crystals.—$K(AsO)A''$ 1½aq. S. 13 at 16°. Decomposed by hot water with liberation of As_2O_3.—$Na(AsO)A''$2½aq. S. 7 at 19°. Non-efflorescent white crystals (Werther, *J. pr.* 32, 385).—$K(SbO)A''$ ½aq. Monoclinic prisms.—Ag_2A''. Shining scales, less sol. Aq than silver tartrate.

Mono-methyl ether $MeHA''$. Formed by evaporating racemic acid with MeOH (Guérin-Varry, *A. Ch.* [2] 62, 77; *A.* 22, 252). Rectangular prisms, v. e. sol. cold water. Decomposed by hot water into the parent substances.—$KMeA''$½aq. Prisms.—$Ba(MeA'')_2$ 4aq. Monoclinic prisms.—$AgMeA''$. Pp.

Di-methyl ether Me_2A''. [85°]. (282° i.V.). Formed by methylation of racemic acid, and also by mixing equal weights of the di-methyl ethers of the lævo- and dextro-tartaric acids (Anschütz a. Pictet, *B.* 13, 1178; 18, 1397; *A.* 247, 116). Monoclinic crystals; optically inactive. Yields a di-acetyl derivative $C_2H_2(OAc)_2(CO_2Me)_2$ [86°] in trimetric crystals; $a{:}b{:}c = {·}8095{:}1{:}{·}6728$. This compound, examined by Raoult's method, has the same molecular weight as the di-acetyl derivative of di-methyl tartrate.

Mono-ethyl ether $EtHA''$. Deliquescent prisms, v. sol. alcohol. Inactive to light.—$KEtA''$ aq.—$Ba(EtA'')_2$ 2aq.—$AgEtA''$. Prisms.

Di-ethyl ether Et_2A''. (238° cor. at 197 mm.) S.G. $\frac{15}{15}$ 1·2098; $\frac{25}{25}$ 1·2021. M.M. 8·759 at 15·5° (Perkin, *C. J.* 51, 364). Yields an oily acetyl derivative and a di-acetyl derivative $C_2H_2(OAc)_2(CO_2Et)_2$, [51°] (230° at 100 mm.). BzCl forms $C_2H_2(OH)(OBz)(CO_2Et)_2$ [57°]. The compound $C_2H_2(OEt)_2(CO_2Et)_2$ (147° at 15 mm.) is formed from di-bromo-succinic ether [58°] and NaOEt (Michael, *J. pr.* [2] 46, 234).—Ag_2A''.—$AgHA''$. Monoclinic, $a{:}b{:}c = {\cdot}721{:}1{:}{\cdot}869$; $\beta = 70° 10'$.

Inactive tartaric acid $CO_2H.CH(OH).CH(OH).CO_2H$. *Mesotartaric acid.* [140°–143°]. S. 125 at 15°.

Formation.—1. By heating cinchonine tartrate or racemate for several hours at 170° (Pasteur, *A.* 88, 212). The product is mixed with $CaCl_2$, which ppts. calcium racemate, and the filtrate slowly deposits calcium inactive tartrate.—2. By boiling tartaric or racemic acid for 400 hours with HClAq (Dessaignes; Pasteur, *Bl.* 1862, 107).—3. By heating tartaric acid (30 g.) or racemic acid with water (4 c.c.) for 2 days at 165°. Separated by means of its very soluble acid K salt (Jungfleisch, *Bl.* [2] 19, 101).—4. A product of the action of HNO_3 on sorbin (Dessaignes, *C. R.* 55, 769), erythrite (Przybytek, *B.* 17, 1412; *Bl.* [2] 43, 126) and glycerin.—5. By oxidation of lævulose (Kiliani, *B.* 14, 2530).—6. By oxidation of phenol by alkaline $KMnO_4$ at 0° (Doebner, *B.* 24, 1755).—7. A product of the action of moist Ag_2O on di-bromo-succinic acid. 8. By the action of nitrous acid on di-amido-succinic acid (Lehrfeld, *B.* 14, 1819).—9. By oxidation of maleïc acid by alkaline $KMnO_4$ (Kekulé a. Anschütz, *B.* 14, 713).

Properties.—Prisms (containing aq). Loses its aq at 100°; at 200° it yields pyrotartaric and racemic acids. Prolonged boiling with HCl aq converts it into racemic acid (Dessaignes). The conversion is also effected by heating the acid with a little water at 175°. The ether is converted by AcCl into $C_2H_2(OAc)_2(CO_2Et)_2$ [48°], crystallising in silky needles.

Salts KHA''. Needles. S. 12·5 at 19°.—$RbHA''\frac{1}{2}aq$. — $Rb_2A''aq$. — $RbNaA''2\frac{1}{2}aq$. — $CaA''3aq$. S. ·17 at 100°. S. (HOAc) ·028 at 18°; ·085 at 100°.—$PbA''aq$: amorphous pp. — $ZnA''2aq$ (dried at 110°). — $TlHA''$. — Tl_2A''.—$NaTlA''2\frac{1}{2}aq$.—$Ag_2A''aq$: white pp.

Metatartaric acid $(C_4H_6O_6)_x$. A deliquescent, glassy mass, v. sol. water, obtained by melting tartaric acid (Braconnot, *A. Ch.* [2] 68, 299; Erdmann, *A.* 21, 9; Laurent a. Gerhardt, *A.* 70, 848). It is sometimes formed when a solution of tartaric acid is evaporated over a water-bath (Grosjean, *C. J.* 43, 334). Converted by boiling water into tartaric acid.

Salts.—$(NH_4)HA''$. Minute needles. More soluble than the acid ammonium tartrate. Its solution is ppd. by $CaCl_2$ and NH_3Aq only when highly concentrated. $CaA''4aq$. Minute lenticular grains, sol. dil. HClAq, converted by boiling water into calcium tartrate.

Ditartaric acid $C_8H_{10}O_{11}$. An anhydride of tartaric acid, got by heating tartaric acid at 170° till it is no longer ppd. by lime-water (Fremy, *A.* 19, 197; 29, 142; 78, 297). Amorphous and very deliquescent. Sol. alcohol, insol. ether. Its salts are amorphous, v. sol. water, and ppd. by alcohol. They are converted into metatartrates, and finally into tartrates, by boiling water.—CaA''.—BaA''.—PbA''.—CuA''.—Ag_2A''. V. sol. water (Schiff, *A.* 125, 129).

Ethyl ether Et_2A''. Fat-like solid.

Tartrelic acid $C_4H_4O_5$. *Soluble tartaric anhydride.* Formed by quickly heating small quantities of tartaric acid till the fused mass swells up. Yellowish deliquescent mass, sol. water, forming an acid solution, from which $CaCl_2$ ppts. CaA'_2 as an amorphous mass, which becomes crystalline on adding alcohol. Tartrelic acid is converted into tartaric acid by boiling water.

Insoluble tartaric anhydride $C_4H_4O_5$. Formed by heating tartaric acid for some time at 150° and exhausting the product with cold water. Powder, insol. water, alcohol, and ether. Converted by hot water into tartaric acid.

TARTRONIC ACID $C_3H_4O_5$ *i.e.* $CH(OH)(CO_2H)_2$. *Oxy-malonic acid.* Mol. w. 120. [187°]. *Heat of solution* −4331 (Gal a. Werner, *Bl.* [2] 46, 803).

Formation.—1. By spontaneous decomposition of nitro-tartaric acid in aqueous solution (Dessaignes, *C. R.* 34, 731; 38, 44).—2. By the reduction of mesoxalic acid by sodium-amalgam (Baeyer, *J.* 1864, 641).—3. By the action of Ag_2O on bromo-malonic acid (Petrieff, *B.* 11, 414).—4. By boiling chloro-malonic ether with KOHAq, the yield being 25 p.c. of the theoretical amount (Conrad a. Bischoff, *A.* 209, 222).—5. From di-bromo-pyruvic acid and baryta-water at 40° (Grimaux, *B.* 10, 903).—6. From glyoxylic acid by treatment with KCy, the resulting nitrile being saponified (Böttinger, *B.* 14, 729).—7. A product of the action of alkaline cupric solution on glucose (Claus, *Z.* [2] 5, 152; *A.* 147, 114).—8. By slow oxidation of glycerin (Sadtler, *B.* 8, 1456; Campani a. Bizzari, *G.* 12, 1).—9. By heating sodium carboxy-tartronate (Gruber, *B.* 12, 514).

Preparation.—1. By boiling the di-nitrate of tartaric acid (20 g.) with alcohol (60 g. of S.G. ·925) (Demole, *B.* 10, 1778).—2. By warming tri-chloro-lactic ether $CCl_3.CH(OH).CO_2Et$ with a 10 p.c. solution of NaOHAq (5 mols.), neutralising with HOAc and ppg. with $BaCl_2$ (Pinner *B.* 18, 752, 2852).

Properties.—Prisms (containing ½aq), v. sol. water and alcohol, sl. sol. ether. After drying at 100° it loses its water of crystallisation and becomes v. sol. ether. Massol (*C. R.* 114, 422) obtained anhydrous crystals [155°]. Decomposed by fusion, yielding CO_2 and glycolide $C_2H_2O_2$. Reduced by HIAq to malonic acid.

Salts.—Na_2A'' (dried at 100°). V. sol. water. — $K_2A''aq$. — $(NH_4)_2A''$. Needles. — $(NH_4)HA''$. Yields glycollic amide on heating. —$BaA''2aq$. Micro-crystalline powder, v. sl. sol. water (Pinner).—$BaA''aq$ (G.).—$CaA''2\frac{1}{2}aq$ (P.). —$CaA''aq$ (C. a. B.).—CdA''.—PbA'' (dried at 120°).—MnA''.—Ag_2A''. Needles (from hot Aq).

Ethyl ether Et_2A''. (c. 224°). Heavy oil (Freund, *B.* 17, 786; Pinner).

The acetyl derivative $CH(OAc)(CO_2Et)_2$ (c. 161° at 60 mm.), S.G. $\frac{12.5}{16}$ 1·131, is formed from bromo-malonic ether and KOAc in EtOH at 50° (Conrad a. Brückner, *B.* 24, 2997). Br converts it into mesoxalic ether $C(OH)_2(CO_2Et)_2$ [57°].

Amide $CH(OH)(CO.NH_2)_2$. [196°]. Six-sided plates, m. sol. hot water.

Amic acid $CO_2H.CH(OH).CO.NH_2$. [160°]. Formed by boiling sodium dialurate with water (Menschutkin, *A.* 182, 82). Needles, sl. sol. cold water. Converted by nitrous acid into glycollic acid.—KA′ aq.—BaA′$_2$ aq.—PbA′$_2$ ½aq. Needles, v. sol. hot water.—AgA′. Needles.

Phenyl derivative $CH(OPh)(CO_2H)_2$. Formed by saponification of its ether $CH(OPh)(CO_2Et)_2$ (230°–240° at 60 mm.), which is got from bromo-malonic ether, phenol, and NaOEt (C. a. B.). At 196° it forms $CH_2(OPh).CO_2H$.

TARTRONYL-UREA *v.* Dialuric acid.

TAURINE $C_2H_7NSO_3$ *i.e.* $CH_2(NH_2).CH_2.SO_3H$. *Amido-ethane sulphonic acid.* Mol. w. 125. S. 6·5 at 12°. H.F. 185,700 (Berthelot a. Matignon, *A. Ch.* [6] 22, 182). Obtained by the action of acids and alkalis on taurocholic acid (Gmelin, *Tiedemann a. Gmelin's Die Verdauung*, 1, 43; Domarçay, *A.* 27, 286; Dumas a. Pelouze, *A.* 27, 292; Redtenbacher, *A.* 57, 170; Strecker, *A.* 65, 132; 67, 34; 91, 101). Occurs in the free state in putrid bile and in the muscles of the oyster, in shark's blood, in the liver, spleen, and kidneys of the ray, and in the lungs of oxen (Valenciennes a. Fremy, *C. R.* 41, 735; Städeler a. Frerichs; Clöetta, *A.* 99, 289). Formed also by heating β-chloro-ethane sulphonic acid with NH_3Aq at 100° (Kolbe, *A.* 122, 33), and by the action of SO_2 on vinylamine (Gabriel, *B.* 21, 2667). Prepared by evaporating ox-bile with dilute HCl at 100°, decanting from a resin, allowing to crystallise, and re-crystallising from water. It may be purified by means of the lead salt.

Properties.—Transparent crystals, m. sol. water, insol. alcohol. Neutral to litmus. Not melted below 240°. Converted by nitrous acid into isethionic acid (Gibbs, *Am. S.* [2] 25, 30). Decomposed by potash-fusion.

Salts.—NaA′. Very deliquescent (Lang, *Bl.* [2] 25, 180).—CaA′$_2$. Slender needles, v. e. sol. water.—PbA′$_2$. Needles, v. e. sol. water.—$Pb_3A'_4(OH)_2$.—CdA′$_2$.—HgA′$_2$.—$Hg_2A'_2O$ (Engel, *Bl.* [2] 23, 532).—AgA′.

Benzoyl derivative $NHBz.C_2H_4.SO_3H$. Formed by heating μ-phenyl-thiazole tetrahydride with HCl and bromine-water (Gabriel a. Heymann, *B.* 23, 159). Syrup.—AgA′. Spherical groups of plates.

Phthalyl derivative $(C_8H_4O_2):N.CH_2.CH_2.SO_3H$. Got by oxidising di-phthalimido-di-ethyl-disulphide with HNO_3 (S.G. 1·25) (Gabriel, *B.* 24, 1116). Crystals (containing 1½aq), sol. EtOAc. Tastes bitter.

Imide $C_2H_4<\begin{smallmatrix}NH\\SO_2\end{smallmatrix}>$. [45°–50°]. Prepared from β-chloro-ethane-sulphonic chloride $CH_2Cl.CH_2.SO_2Cl$ by treatment with ammonia (James, *C. J.* 49, 491). Solid, resembling gum arabic; bitter in taste. V. sl. sol. cold, v. sol. hot, water, insol. alcohol and ether. Ppd. HgO appears to form the compound $(C_2H_4SO_2N)_2Hg$.

Ethyl-taurine *v.* Ethyl-amido-ethane sulphonic acid.

Methyl-taurine *v.* Methyl-amido-ethane sulphonic acid.

TAUROCHENOCHOLIC ACID $C_{29}H_{49}NSO_6$. Occurs as K and Na salts in goose-bile (Heintz a. Wislicenus, *P.* 108, 547; Otto, *A.* 149, 192). Amorphous, sol. water and alcohol. Decomposed by boiling with baryta or potash into taurine and chenocholic acid.—NaA′aq (dried at 110°). Small tables. Its aqueous solution gives pps. with $CaCl_2$, $AgNO_3$, and lead subacetate, but not with lead acetate.

TAUROCHOLIC ACID $C_{26}H_{45}NSO_7$. Occurs as Na salt in the bile of most animals (Strecker, *A.* 67, 30; 70, 169; Hüfner, *J. pr.* [2] 19, 302; Copeman a. Winston, *J. Physiol.* 10, 213). Obtained by ppg. with lead acetate, filtering from lead glycocholate, and ppg. lead taurocholate by lead subacetate. Deliquescent silky needles, v. sol. water and alcohol, m. sol. ether. Dextrorotatory, $[\alpha]_D = 25°$ (Hoppe-Seyler, *Arch. Path. Anat.* 15, 126). Boiling water splits it up into taurine and cholic acid. Antiseptic, and ppts. albumen completely from its solutions (Maly, *M.* 4, 89).

Salts.—NaA′ (dried at 120°). Ppd. by alcohol in an amorphous state, rendered crystalline by ether.—KA′. Needles, resembling wavellite.

TAUROCYAMINE $C_3H_9N_3SO_3$ *i.e.* $NH:C(NH_2).NH.CH_2.CH_2.SO_3H$. [226°]. S. 4 at 21°. Formed by heating taurine with cyanamide (1 mol.) and water at 110° (Engel, *B.* 8, 1597; Dittrich, *J. pr.* [2] 18, 63). Small white prisms, v. sol. water, insol. alcohol and ether. From cold water it crystallises with aq.

TAXINE $C_{37}H_{52}NO_{10}$. [82°]. Obtained from the leaves, twigs, and fruit of the yew (*Taxus baccata*) by extracting with ether (Lucas, *Ar. Ph.* [2] 85, 145; Van der Harst, *R. T. C.* 3, 279; Marmé, *Bl.* [2] 26, 417; Hilger a. Brande, *B.* 23, 464). The ethereal solution is quickly shaken with acidulated water, and the solution ppd. by NH_3Aq. Crystalline. Gives off aromatic fumes on melting. V. sl. sol. water, v. sol. alcohol and ether, insol. benzene. Conc. H_2SO_4 gives a deep purple; Fröhde's reagent a reddish-violet colour. Gives yellow pps. with sodium phosphomolybdate, I in KI, and potassium bismuth iodide. Insol. alkalis. The salts crystallise with difficulty.—**Salts:** B′HCl.—$B'_2H_2SO_4$.—$B'_2H_2PtCl_6$.—$B'HAuCl_4$.—B′EtI.

TECTOQUINONE. [171°]. Obtained from teak resin or by the distillation of teak wood (Romanis, *C. J. Proc.* 4, 116). Amber-yellow crystals, sol. alcohol. Reduced by zinc-dust and HOAc to $C_{18}H_{22}$. Yields a nitro-derivative and a bromo-derivative [165°].

TELLURATES. Salts of telluric acid, H_2TeO_4 (*q.v.*, p. 649). The *normal tellurates* of monovalent metals have the composition $M_2TeO_4.xH_2O$; there are also *acid tellurates* $MHTeO_4.xH_2O$; and two classes of *tetratellurates*, (1) $M_2Te_4O_{13}.xH_2O$, which are soluble in water when M is an alkali metal, and (2) $M_2Te_4O_{13}$, which are insoluble in water. The hydrated tetratellurates may be represented as *acid ditellurates* derived from the hypothetical acid $H_2Te_2O_7$; thus $K_2Te_4O_{13}.4H_2O = 2KHTe_2O_7.3H_2O$. Some acid salts may be represented as derived from hypothetical ditelluric acid, *e.g.*

$$PbTe_2O_7\ (= PbTeO_4.TeO_3).$$

The normal alkali tellurates are obtained by saturating H_2TeO_4 with MOHAq or M_2CO_3Aq and crystallising. Alkali acid tellurates, and hydrated tetratellurates, are obtained by interactions of acids with the normal tellurates; anhydrous (insoluble) tetratellurates of the alkali

metals are formed by heating the acid tellurates; thus $6KHTeO_4 = K_2Te_4O_{13} + 2K_2TeO_4 + 3H_2O$. Most of the other tellurates are obtained from the alkali salts by double decomposition.

The alkali tellurates, other than those of the form $M_2Te_4O_{13}$, are soluble in water; most of the other tellurates are insoluble or sparingly soluble in water. Tellurates generally dissolve easily in HClAq; the solutions are not ppd. by water, but on boiling the solutions become yellow, give off Cl, and then yield a pp. of H_2TeO_3 on addition of water. Acidulated solutions of tellurates are slowly decomposed by H_2S, probably with ppn. of TeS_3 (*v.* TELLURIUM SULPHIDES, p. 655). Solutions of tellurates are slowly reduced by SO_2, more quickly on heating, with separation of Te. When tellurates are heated to redness they give off O and form tellurites; heated with K_2CO_3 and charcoal, they give K_2Te.

The tellurates have been examined chiefly by Berzelius (*P.* 32, 577); and some of them also by Oppenheim (*J. pr.* 71, 267).

Potassium tellurates. The *normal salt* $K_2TeO_4.5$aq is obtained by dissolving H_2TeO_4 and K_2CO_3, in the ratio $H_2TeO_4:K_2CO_3$, in hot water and crystallising; also by dissolving H_2TeO_4 in excess of KOHAq, heating, and allowing to cool slowly. Crystallises in rhombic prisms, isomorphous with K_2SO_4 (Handl, *J.* 1861. 266). The crystals become moist in air and form $KHTeO_4.x$aq and K_2CO_3. The *acid salt* $2KHTeO_4.3$aq separates on adding to K_2TeO_4Aq sufficient H_2SO_4Aq, or other strong acid, to remove half the potassium; the salt is crystallised from hot water. This salt is slightly soluble in cold water, but much more soluble in hot water; when heated it is converted into K_2TeO_4 and $K_2Te_4O_{13}$. The *tetratellurate* $K_2Te_4O_{13}$ is obtained, as a yellow powder, by heating $2KHTeO_4.3$aq below redness and washing out K_2TeO_4 in water. $K_2Te_4O_{13}$ is insoluble in water, also in HClAq or HNO_3Aq except after prolonged boiling. The *hydrated tetratellurate* $K_2Te_4O_{13}.4H_2O$—which may also be regarded as an *acid ditellurate* $2KHTe_2O_7.3H_2O$—is formed by adding H_2SO_4Aq, or another strong acid, to K_2TeO_4Aq in quantity to remove 6K from $4K_2TeO_4$ ($4K_2TeO_4Aq + 3H_2SO_4Aq = K_2Te_4O_{13}Aq + 3H_2O + 3K_2SO_4Aq$), and crystallising. The salt is fairly soluble in cold water; it is partly decomposed to $KHTeO_4$ and H_2TeO_4Aq by repeatedly crystallising in aqueous solution.

The following tellurates have been described (Berzelius, *l.c.*; Oppenheim, *l.c.*): *Ammonium salts* $(NH_4)_2TeO_4$, $(NH_4)_2Te_2O_7$, $(NH_4)_2Te_4O_{13}$, obtained by ppg. solutions of the corresponding salts of K or Na with NH_4Cl. *Barium salts* $BaTeO_4.3$aq, $BaH_2(TeO_4)_2.2$aq, $BaTe_4O_{13}$, obtained by ppn. *Cadmium salt* $CdTeO_4$, obtained by ppn. *Calcium salt* $CaTeO_4$, obtained by ppn. *Lead salts* $PbTeO_4$, $PbTe_2O_7$, $PbTe_4O_{13}$, by ppn; a basic salt is also said to exist. *Silver salts* Ag_2TeO_4, and several basic salts $xAg_2O.yTeO_3$. *Sodium salts* $Na_2TeO_4.x$aq, $NaHTeO_4.x$aq, $NaHTe_2O_7.x$aq, and $Na_2Te_4O_{13}$, obtained similarly to the potassium salts. Tellurates of Al, Cr, Co, Cu, Fe, Li, Mg, Mn, Hg, Ni, and Sr have also been described, but only very superficially.

M. M. P. M.

TELLURHYDRIC ACID H_2Te; *v.* HYDROGEN TELLURIDE, vol. ii. p. 727.

TELLURIC ACID H_2TeO_4; crystallises from solutions as $H_2TeO_4.2H_2O$.

Formation.—1. By oxidising Te by *aqua regia.*—2. K_2TeO_4 is formed by the interaction of Cl with K_2TeO_3Aq, also by fusing TeO_2 with KNO_3 or $KClO_3$.

Preparation.—1. A mixture of TeO_2, $KClO_3$, and KOH, in the ratio $TeO_2:2KClO_3:2KOH$ is thoroughly fused; the fused mass is dissolved in water and $BaCl_2$Aq is added; the pp. of $BaTeO_4$ is purified by recrystallisation from hot water, and is then dried at 100°; the dry $BaTeO_4$ is mixed with its own weight of water and one-fourth its weight of conc. H_2SO_4, and heated till decomposition is complete, when $BaSO_4$ is removed by filtration, and the filtrate is evaporated at 100° to the crystallising point; the crystals that separate are dried, powdered, washed repeatedly with alcohol to remove H_2SO_4, and recrystallised from water (Oppenheim, *J. pr.* 71, 267). Berzelius (*P.* 28, 392; 32, 1) fused TeO_2 with an equal weight of K_2CO_3 or Na_2CO_3, dissolved in water, added KOH equal to the weight of TeO_2 used, passed in Cl until the liquid smelt strongly thereof, ppd. by $BaCl_2$Aq, and proceeded as described above.—2. TeO_2 is dissolved in HNO_3Aq, the solution is boiled with PbO_2 and filtered, Pb is ppd. from the filtrate by H_2SO_4Aq, the filtrate from $PbSO_4$ is evaporated to dryness at 100°, the residue is digested with alcohol and ether to remove H_2SO_4, and is then crystallised from hot water *in vacuo* (Becker, *A.* 180, 257).

Properties and Reactions.—$H_2TeO_4.2H_2O$ is obtained by slow crystallisation in white, monoclinic crystals, resembling gypsum, S.G. 2·9999 at 25·5° (Clarke, *Am. S.* [3] 16, 401). When obtained by rapid evaporation $H_2TeO_4.2H_2O$ appears as a glassy solid. Heated to c. 130° H_2TeO_4 is obtained; decomposition begins at a little above 160° to TeO_3 and H_2O, and at c. 180° TeO_3 begins to decompose to TeO_2 and O, this decomposition being complete at c. 350° (Wills, *C. J.* 35, 704). H_2TeO_4 has S.G. 3·425 at 18·8° (Clarke, *l.c.*). $H_2TeO_4.2H_2O$ is slightly soluble cold water; it is dissolved fairly easily by boiling water; soluble in acid and alkali solutions; almost, if not quite, insoluble in alcohol. H_2TeO_4 dissolves very slowly in boiling water. Aqueous solutions of H_2TeO_4 have a metallic, not a sour, taste; they very slightly redden litmus. Thomsen (*Th.* 2, 277) gives the following H.F.: $[Te,O^3,Aq] = 98,380$; $[TeO^3Aq,O] = 21,200$. H_2TeO_4 dissolves gradually in hot, fairly conc. HClAq, with evolution of Cl and formation of H_2TeO_3Aq. H_2TeO_4Aq is not reduced by passing H_2S into it, but if the solution is saturated with H_2S and kept in a warm place, in a closed flask, for some time, the liquid becomes brown, and flakes, probably of TeS_3 (*v.* TELLURIUM SULPHIDES, p. 655), are deposited.

H_2TeO_4Aq reacts with alkalis to form salts M_2TeO_4 and $MHTeO_4$; salts of the forms $MHTe_2O_7$ and $M_2Te_4O_{13}$ are also known (*v.* TELLURATES, p. 648).

M. M. P. M.

TELLURIDES. Any compound of Te with a single element more positive than itself is called a telluride. Tellurides of the heavier metals are generally formed by melting the metals with Te, also by passing H_2Te into solutions of salts of the metals; tellurides of K and Na are formed by heating TeO_2 with K_2CO_3 or Na_2CO_3 and charcoal; many tellurites and tellurates give tellurides when heated in a current of H. Te ppts. tellurides of Cu, Ag, and some other metals, by boiling solutions of salts of these metals with Te (Parkmann, *C. C.* 1862. 814). Tellurides of K and Na dissolve in water with a red colour; this colour is due either to polytellurides or to the presence of traces of oxides according to Demarçay (*Bl.* [2] 40, 99). Berthelot a. Fabre (*C. R.* 105, 92) obtained colourless solutions of alkali tellurides by passing pure H_2Te into solutions of alkalis; a trace of O produced a red colour and separated Te. Tellurides react with HClAq giving off H_2Te; they are oxidised to tellurites by HNO_3Aq, and to tellurites and tellurates by *aqua regia*. Warmed in Cl tellurides give metallic chlorides and $TeCl_4$.

Tellurides of Sb, As, Bi, Au, Fe, K, Ag, and Na are mentioned under these metals (*cf.* Brauner, *C. J.* 55, 388). M. M. P. M.

TELLURITES. Salts of tellurous acid H_2TeO_3 (*q. v.*, p. 656). The *normal* and *acid tellurites* of monovalent metals belong to the forms M_2TeO_3 and $MHTeO_3$. Some salts are also known containing relatively more of the acidic radicle; these may be formulated as $M_2O.xTeO_2$ where x is 2 and 4; or they may be regarded as $M_2TeO_3.xTeO_2$, where x is 1 and 3; or finally these *hyperacid salts* may be looked on as $M_2Te_2O_5$ and $M_2Te_4O_9$—that is, as derivatives of the hypothetical acids $H_2Te_2O_5$ and $H_2Te_4O_9$.

Tellurites are generally formed by heating together basic oxides and TeO_2 in the proper proportions; some tellurites of the heavier metals are obtained by ppn. from solutions of alkali tellurites. Tellurites of the alkali metals dissolve readily in water; those of the alkaline earth metals are less soluble; the others are insoluble in water. Most tellurites dissolve in HClAq, forming yellow solutions which do not give off Cl on heating; this reaction distinguishes them from tellurates (*v.* p. 649). Solutions of tellurites in a little HClAq deposit H_2TeO_3 on dilution. Most tellurites are fusible, and crystallise on cooling; the hyperacid alkali tellurites form colourless glass-like solids after fusion. By strongly heating with charcoal and K_2CO_3 most tellurites give K_2Te.

Tellurites of potassium. The *normal salt* K_2TeO_3, and the *acid salt* $K_2TeO_3.TeO_2$ ($=K_2Te_2O_5$ or $K_2O.2TeO_2$) are prepared by fusing TeO_2 with K_2CO_3 in the proper proportions. K_2TeO_3 melts at a red heat; dissolves slowly in cold water, more quickly in boiling water; the aqueous solution has an alkaline taste and reaction, and is decomposed by the CO_2 in the air. $K_2O.2TeO_2$ melts below redness, and solidifies again to a transparent, colourless, crystalline mass; dissolved by boiling water, and the solution on cooling deposits $K_2O.4TeO_2$. The *tetra-tellurite* or *hyperacid tellurite* $K_2O.4TeO_2.4H_2O$ ($=K_2TeO_3.3TeO_2.4H_2O$ or $K_2Te_4O_9.4H_2O$) is prepared by boiling H_2TeO_3Aq with K_2CO_3 and filtering at 100°; the salt is deposited on cooling in microscopic six-sided prisms and tablets. This salt reacts with cold water to give a solution of K_2TeO_3 and $K_2Te_2O_5$ and a gelatinous pp. of H_2TeO_3; when heated $4H_2O$ is given off, and $K_2O.4TeO_2$ remains as a salt which melts at a moderate red heat and solidifies on cooling to a colourless glass.

The tellurites have been examined chiefly by Berzelius (*P.* 32, 577; *v.* also Oppenheim, *J. pr.* 71, 267). Salts of the following metals have been isolated, but many have been studied in a very superficial way: Al, NH_4, Ba, Cd, Ca, Cr, Co, Cu, Fe, Pb, Li, Mg, Mn, Hg, Ni, Ag, Na, Sr, and Zn. M. M. P. M.

TELLURIUM. Te. At. w. c. 125 (*v. infra*). Mol. w. c. 250 (*v. infra*). Melts at c. 455° (Carnelley a. Williams, *C. J.* 37, 125). Boils at c. 1390° (Deville a. Troost, *C. R.* 91, 83). S.G. 6·2549 at 0° (after compression); 6·2322 at 0° (uncompressed) (Spring, *B. B.* 5, 854); 6·2549 at 18·2° (after melting in H) (Přiwoznik, *C. C.* 1892. ii. 962; for further data *v.* Clarke's *Table of Specific Gravities* [2nd ed.] 10). V.D. at c. 1390° to c. 1440° = 130 (Deville a. Troost, *C. R.* 56, 891). S.H. (21° to 51°, crystalline) ·0475 (Kopp, *T.* 1865. 71); (at 98°, crystalline) ·0483; (at 98°, after distillation in SO_2) ·0518 (Fabre, *A. Ch.* [6] 14, 101). C.E. (linear, at 0°) ·00001675 (Fizeau, *C. R.* 68, 1125). E.C. ·000777 at 19·6 (Ag at 0° = 100) (Matthiesen, *P.* 103, 428); conductivity increases slightly when light falls on Te; the increase is very much less than in the case of Se (*v.* Adams a. Day, *Pr.* 24, 163; 25, 113). E.C. decreases slightly to c. 100°-140°, and then increases to 200°; on cooling after fusion E.C. decreases regularly and markedly; the following values are given by Exner (*P.* 158, 625) ·0035 at 200°, ·00286 at 20° (after fusion), ·000435 at 20° (after very slow cooling from fusion). Te crystallises in rhombohedra; $a{:}c = 1{:}1{\cdot}3298$; it is isomorphous with S and Se (*v.* Muthmann, *Z. P. C.* 8, 396). For emission-spectrum *v.* Plücker a. Hittorf (*Pr.* 13, 153); Thalen; Salet (*A. Ch.* [4] 28, 51); Ditte (*C. R.* 73, 622); Hartley a. Adeney (*T.* 1884 [1] 117). For absorption-spectrum of vapour of Te *v.* Gernez (*C. R.* 74, 1190). H.C. $[Te,O^3,Aq] = 98,380$ (*Th.* 2, 278).

Historical.—Examining a mineral containing gold from the Seven Mountains in 1782 Müller von Reichenstein suspected the presence of a new metal (*Abhand. einer Privatgesellschaft in Böhmen*). He sent a specimen of the mineral to Bergmann, who said that it contained a metal which was not the same as that in blende. In 1798 Klaproth received some of the mineral from M. von R., and isolated the characteristic element, to which he gave the name tellurium (from *tellus* = the earth) (K., *Beiträge zur chem. Kenntniss der Mineralkörper*, 3, 1; *cf. Crell's Ann.* 1798. 91; and *G. A.* 12, 246). The compounds of Te were more fully examined by Berzelius (*S.* 6, 311; 34, 78; *P.* 8, 411; 28, 392; 32, 1, 577).

Occurrence.—Te is found native, in small quantities, and in a few localities—chiefly in Hungary and Transylvania, and in Virginia, U.S.; it generally accompanies Au and Ag; specimens have been obtained with 97–98 p.c. Te. Tellurides are also found in small quantities in Hungary, Mexico, California, Bolivia, and some other places; in considerable quantities in Colorado; these are generally compounds of Te with Bi, Ag, Pb, Bi and S, Ag and Au, Au, Pb and Sb; *tellurite* (or *tellurium-ochre*) containing TeO_2 is found in small quantities in the Seven Mountains (*v.* G. Rose, *P.*

18, 64; Rammelsberg, *J. M.* 1874. 30; Burkart, *J. M.* 1873. 476; Silliman a. Marvine, *Am. S.* [3] 8, 25; Mathewson, *J. M.* 1866. 93; Genth, *J. M.* 1875. 188, 314).

Formation.—1. By passing SO_2 into H_2TeO_3Aq; $H_2TeO_3Aq + 2SO_2 + H_2O = 2H_2SO_4Aq + Te$. Also by ppg. solution of $TeCl_4$ in dilute HClAq, or of a Te compound in H_2SO_4Aq, by an alkali sulphite. 2. By reducing a boiling solution of $(NH_4)_2TeO_4Aq$ by grape sugar (Stolba, *J.* 1873. 214).—3. By decomposing K_2TeAq by air or oxygen (*v.* Oppenheim, *J. pr.* 71, 267; 81, 308; Himly, *J.* 1877. 213).—4. By ppn., by means of zinc, from solutions of Te compounds in H_2SO_4Aq (*v.* Löwe, *J. pr.* 60, 163).

Preparation.—There are several methods of preparing crude Te from the minerals that contain it. Native bismuth telluride is made into a paste with oil and K_2CO_3, and gradually heated to whiteness in a covered crucible; K_2Te is extracted from the fused mass by boiling water, and the solution deposits Te on standing in air. Or the mineral containing Te is powdered and treated with dilute HClAq; the insoluble matter is gradually added to three times its weight of conc. H_2SO_4, and heating is continued until SO_2 ceases to be given off; the solid that forms on cooling is dissolved in water containing a little HCl; the solution is filtered from AgCl, Te is ppd. from the filtrate by zinc, and undissolved zinc is removed by digestion with dilute HClAq. For details and other methods *v.* Berzelius (*P.* 8, 411; 28, 392); Löwe (*J. pr.* 60, 163); Wöhler (*A.* 84, 69); Oppenheim (*J. pr.* 81, 308); Schnitzer (*D. P. J.* 211, 484, 492); Schwarz (*D. P. J.* 186, 29).

To prepare pure Te, Brauner (*C. J.* 55, 382; *cf. M.* 10, 411) recommends to digest the crude material with HClAq in a large flask, and to oxidise by HNO_3Aq added little by little till the solid matter becomes white, to evaporate several times with conc. HClAq (to remove HNO_3), and then to dilute cautiously with water, taking care not to add enough water to ppt. H_2TeO_3 along with any $PbCl_2$ which may come down. He then adds some saturated SO_2Aq, warms to 60°-70°, and ppts. Te by passing SO_2 into the warm solution. The Te thus obtained generally contains a little copper and lead selenides. The pp. is dried and fused in small portions with KCy; the fused mass, which contains K_2Te, is dissolved in water, from which air has been removed, in a stoppered flask; the liquid is allowed to clear (there is generally a small pp. of tellurides of heavy metals mixed with a trace of Te) and is then poured off, and a current of air is passed through it, whereby Te is ppd. The Te is dried, placed in a porcelain boat, which is introduced into a wide tube of hard glass surrounded by wire gauze, and distilled in a current of pure dry H. (For a method of purification based on the ppn. of Te from $(NH_4)_2TeO_4Aq$ by grape sugar, *v.* Stolba, *J.* 1873. 214.)

Properties.—As prepared by sublimation in H, tellurium is a white, shining, crystalline, very brittle solid, unchanged by exposure to air. During distillation in H, Brauner (*l.c.*) noticed that some H_2Te was formed, and was decomposed with deposition of needle-shaped crystals of Te, some of which were 1 centim. in length. The crystals of Te are hexagonal rhombohedra, isomorphous with S and Se (*v.* Muthmann, *Z. P. C.* 8, 396). By allowing K_2TeAq to decompose in air, H. Rose obtained six-sided prisms with rhombohedral summits (*P.* 21, 443; *cf.* Fabre a. Berthelot, *C. R.* 104, 1405). Amorphous Te is obtained as a brown powder by ppg. H_2TeO_3Aq by SO_2; on warming, the amorphous variety changes to the crystalline, giving off a large quantity of heat (F. a. B., *l.c.*). Te that has been melted and cooled quickly seems to contain both the crystalline and the amorphous varieties. According to Fabre (*A. Ch.* [6] 14, 100), both varieties have practically the same S.H. at c. 100°. Te melts at c. 455° and boils at c. 1390°; the vapour is golden yellow. Heated in air it burns with a brilliant blue-green flame to white clouds of TeO_2, which are poisonous; the smell, like that of decaying radishes, that is noticed on burning impure Te is due to the oxidation products of Se, which is commonly present in specimens of crude Te. Te dissolves in very conc. boiling KOHAq, forming a red liquid that contains K_2TeO_3 and K_2Te; on allowing to cool, or on adding water, the whole of the Te separates. HClAq is without action on Te; conc. hot H_2SO_4 dissolves it slightly, but the Te separates on dilution; when heated strongly with conc. H_2SO_4 Te dissolves to H_2TeO_3 with evolution of SO_2. Te dissolves in SO_3, forming $TeSO_3$. Conc. HNO_3Aq forms a solution of H_2TeO_3; *aqua regia* forms H_2TeO_3 and some H_2TeO_4. Molten KNO_3 produces K_2TeO_4.

In its physical properties Te approaches the metals, and especially resembles Sb. In its chemical properties Te is, on the whole, non-metallic; but the oxide TeO_2 combines with certain anhydrides of strong acids to form salt-like compounds, and the oxide TeO is said to dissolve in H_2SO_4Aq, forming $Te(SO_4)_2$. Te is closely related to Se, and less closely to S; it shows distinct analogies with Cr, Mo, W, and U (*v.* Oxygen group of elements, vol. iii. p. 705, and Chromium group of elements, vol. ii. p. 168). The atom of Te is divalent in the gaseous molecules TeH_2 and $TeCl_2$, and tetravalent in the gaseous molecule $TeCl_4$.

Atomic weight of tellurium. The at. w. of Te was determined by Berzelius in 1812, 1818, and 1832 by oxidising Te by HNO_3Aq and weighing the TeO_2 produced; he obtained values varying from 127·9 to 128·5 (*P.* 8, 24; 28, 395; 32, 16). In 1857 von Hauer analysed K_2TeBr_6, and obtained values from 126·5 to 128·1 (*W. A. B.* 25, 135). In 1879 Wills determined the weight of TeO_2 obtained by oxidising Te by HNO_3Aq and by *aqua regia*, and he also made analyses of K_2TeBr_6; his results varied from 126·1 to 129·3 (*C. J.* 35, 704). In 1883 Brauner obtained numbers varying from 124·94 to 125·4, by oxidising Te to TeO_2, by converting Te and TeO_2 into $(TeO_2)_2SO_3$, and by synthesising Cu_2Te (*J. R.* 1883. [1] 433; abstract in *B.* 16, 3055). In 1889 Brauner made a very careful revision of the at. w. of Te (*C. J.* 55, 382):—(i.) by oxidising Te to TeO_2 he obtained values varying from 124·48 to 127·28; (ii.) by converting TeO_2 into $(TeO_2)_2SO_3$, the numbers varied from 124·7 to 129 (one result gave 135·9); (iii.) by conversion of Te into $(TeO_2)_2SO_3$, the numbers varied from 124·3 to 129·7; (iv.) by syntheses of tellurides of Ag, Cu, and Au, the numbers varied from 125·7 to 129·9; (v.) by analysis of TeO_2 the value 127·2 was obtained, but only one satisfactory analysis was made; (vi.) by analyses of $TeBr_4$ the numbers varied from 127·27 to 127·31. The results obtained by analysing $TeBr_4$ were more concordant than any obtained by the other methods; but the value 127·3 is almost ·75 units greater than the at. w. of iodine; hence it seems as if the at. w. of Te is greater than that of I. But if this is so, Te must be separated from S, Se, and the chromium metals, which are placed in Group VI. in the periodic arrangement of the elements; and Te must be placed either with the halogens in Group VII. (I being put into Group VI.), or this element must find a place in Group VIII. (I remaining in Group VII., and an empty place being left in Group VI., Series 7). The chemical properties of Te show that it belongs to the same group as S and Se; and the chemical properties of I make it impossible to place that element elsewhere than with F, Cl, and Br.

Is tellurium a homogeneous body? Rather than doubt the applicability of the periodic law, Brauner made the hypothesis that tellurium is not a homogeneous body, but that it contains an admixture of foreign substances. He dissolved Te, and ppd. in fractions by SO_2, fused the fractions with KCy, dissolved in water, and ppd. fractionally by a current of air; he then distilled each fraction in H, and converted it into $TeBr_4$, and analysed each fraction. The values thus obtained for the at. w. of Te were almost identical, the mean being 127·33. Pure TeO_2 was then dissolved in HClAq, and the solution was ppd. in eight fractions by ammonia; the filtrate from the eighth fraction was ppd. by SO_2 in presence of HClAq; after boiling off SO_2 from the filtrate from the ninth fraction, the liquid was saturated with H_2S, and the TeO_2 in solution was obtained, converted into Te, and this converted into $TeBr_4$; the at. w. thus obtained (in three experiments) was 127·32, the three experiments agreeing extremely well. Te was then fused, but not distilled, in a current of H; it was then converted into $TeBr_4$, which was freed from $TeBr_2$ by fractional sublimation *in vacuo*, without converting the $TeBr_4$ into vapour, and analysed; the values obtained for the at. w. of Te differed very much, ranging from 128·5 to 137·4. From these results Brauner concluded that 'if tellurium, obtained by any process of fractionation whatever, be subjected to distillation in a current of hydrogen, and the tetrabromide be prepared from this by sublimation in a vacuum, its analysis always gives the same atomic weight for tellurium. . . . If, however, the tellurium be only fused in a current of an indifferent gas, and the tetrabromide be not sublimed, higher numbers will be obtained. . . . It is therefore very probable that on distilling tellurium in a current of hydrogen, and the tetrabromide in a vacuum, one constituent of tellurium escapes partly, the presence of which in the last cases renders the atomic weight higher.' Brauner prepared $TeBr_2$ by fusing $TeBr_4$ with excess of Te, and subliming either *in vacuo* or in a current of CO_2; the analyses of different specimens of $TeBr_2$ showed percentages of Br varying from 54·658 to 55·14; the percentage of Br calculated for Te = 127·32 is 55·6. Brauner concluded that '*tellurium is not a simple substance.*' This conclusion is still held by B. to be correct. In a private communication (January 1894) he says: 'I consider Te to be a mixture of two elements that cannot be separated by ordinary chemical means, not even by fractionation. It cannot, however, be shown that the at. w. of Te is about 125, for all attempts I have made in this direction have failed completely. All atomic weight determinations made by me, and others, giving values higher or lower than 127·3 are due, partly to impurities, but in most cases to some undetected source of error.'

Molecular weight of tellurium. Deville a. Troost (*C. R.* 56, 891) found the V.D. of Te between c. 1390° and c. 1440° to be 130; this gives the mol. w. of c. 260. As the at. w. of Te is not known with certainty, it is not possible at present to correct the value deduced for the mol. w. from the determinations of V.D. The gaseous molecule of Te is diatomic.

Reactions and Combinations.—1. Heated in *air*, or *oxygen*, Te is burnt to TeO_2.—2. Heated in excess of *chlorine* $TeCl_4$ is produced; with *bromine* $TeBr_4$ is produced; with *iodine* the product is TeI_2.—3. Te and *sulphur* can be melted together in all proportions; it is doubtful whether definite compounds are formed or not (*v.* Tellurium sulphides, p. 655). Te and *selenion* can also be melted together in all proportions; no definite compound has been isolated.—4. *Nitric acid* forms H_2TeO_3; according to Klein a. Morel (*Bl.* [2] 43, 198), cold HNO_3Aq first forms $4TeO_2.N_2O_5.xaq$ (*v.* Tellurium dioxide, p. 655). *Aqua regia* produces a mixture of H_2TeO_3 and H_2TeO_4.—5. Te dissolves in hot conc. *potash solution*, forming a red solution that contains K_2Te and K_2TeO_3; on addition of water Te separates ($2K_2TeAq + K_2TeO_3Aq = 3K_2OAq + 3Te$).—6. Fusion with *potassium nitrate* produces K_2TeO_4.—7. Fusion with *potassium carbonate* produces a mixture of K_2Te and K_2TeO_3.—8. Te dissolves in *sulphur trioxide*, forming $TeSO_3$ (*v. thio-oxide* under Tellurium oxides, p. 655).

Detection and Estimation.—Free Te is readily detected by fusing with charred cream of tartar and dissolving in water, whereby a red solution is obtained that deposits Te in dark-brown flakes on standing in air. Tellurous acid and tellurites dissolve in dilute HClAq, and addition of water ppts. white H_2TeO_3; SO_2 ppts. Te from solutions of tellurites in dilute HClAq or HNO_3Aq. Solutions of tellurates in acids give no pps. with water; solutions in HClAq give off Cl on boiling, being reduced to tellurites, and are then ppd. by water. For a test for Te based on the formation of red $TeSO_3$ by passing TeH_2 into H_2SO_4Aq *v.* Divers a. Shimosé, *C. J.* 43, 329. Te is generally estimated by ppg. the element, from solution of H_2TeO_3 or a tellurite, by alkali sulphite, SO_2, or grape sugar (Kastner, abstract in *C. J.* 29, 440; *cf.* Donath, abstract in *C. J.* 60, 242). In *C. J.* 59, 238, Brauner describes a method for the volumetric estimation of Te by $KMnO_4Aq$.

Tellurium, acids of; *tellurhydric acid* H_2Te (vol. ii. p. 727); *tellurous acid* H_2TeO_3 (this vol., p. 656); *telluric acid* H_2TeO_4 (this vol., p. 649). The existence of the potassium salt of HCNTe is probable (*v.* Tellurocyanides, vol. ii. p. 353).

Tellurium, alloys of. The compounds of Te with metals are sometimes classed with the more definite alloys (*v.* TELLURIDES, p. 649).

Tellurium, antimonides of, *v.* ANTIMONY; *Combinations*, No. 7, vol. i. p. 283.

Tellurium, arsenides of, *v.* ARSENIC; *Combinations*, No. 6, vol. i. p. 303.

Tellurium, bromides of. Two bromides have been isolated, $TeBr_2$ and $TeBr_4$; both are formed by the direct combination of Te and Br. The bromides can be sublimed, under reduced pressure, without change. The V.D. of neither has been determined; but, from the analogy of $TeCl_2$ and $TeCl_4$, the formulæ are probably molecular.

TELLURIUM DIBROMIDE $TeBr_2$. Formula probably molecular, from analogy of $TeCl_2$. Prepared by fusing $TeBr_4$ with excess of powdered Te, and subliming either *in vacuo* or in a current of dry CO_2. A blackish-green crystalline mass; obtained in steel-grey needles by slow sublimation (Brauner, *C. J.* 55, 410). Melts c. 305°, and boils c. 343° (Carnelley, *Melting- and Boiling-point Tables*, 1, 21). $TeBr_2$ is very hygroscopic; it is decomposed by water to H_2TeO_3Aq and HBrAq. Dissolves in tartaric acid solution, forming $TeBr_4$ and Te (Brauner, *l.c.*).

TELLURIUM TETRABROMIDE $TeBr_4$. (*Telluric bromide.*) Formula probably molecular, from analogy of $TeCl_4$. Prepared by shaking together powdered Te and Br, in the proportion Te:4Br, warming in a current of dry CO_2, and then subliming *in vacuo* (for details and description of apparatus, *v.* Brauner, *C. J.* 55, 396). Forms a crystalline crust, which is fiery red when hot and orange coloured when cold. S.G. $\frac{15^\circ}{4^\circ} = 4{\cdot}31$ (Brauner, *l.c.*, p. 407). Melts at c. 380°, and boils at 414°–427°, according to Carnelley a. Williams (*C. J.* 35, 563; 37, 125). Dissolves in a little water without change; on dilution a colourless liquid is obtained, containing HBr and H_2TeO_3; crystals are obtained by evaporating over H_2SO_4, and are said by Berzelius to be $TeBr_4.xH_2O$. By adding $AgNO_3Aq$ to a solution of $TeBr_4$ in tartaric acid, Brauner (*C. J.* 55, 398) obtained AgBr and also crystalline scales probably $(C_4H_4O_5)_2.Ag_2O.TeO_2.2aq$; this compound is called by B. *tellurium-silver tartar emetic* (*cf.* Klein a. Morel, *C. R.* 100, 1140). $TeBr_4$ forms *double salts* with alkali bromides. The salt $TeBr_4.2KBr$ ($=K_2TeBr_6$) is prepared by dissolving the proper quantity of KBr in water, adding Te, running in Br, shaking till the Te is dissolved, filtering, and evaporating at 100° (Wills, *C. J.* 35, 711; *cf.* von Hauer, *W. A. B.* 25, 135). Dark-red, opaque, lustrous crystals; orthorhombic, $a:b:c = 1:1{\cdot}4901:1{\cdot}3658$ (W., *l.c.*); *cf.* Wheeler (*Am. S.* [3] 45, 267), where some other salts of the form M_2TeBr_6 are described.

Tellurium, chlorides of. Two compounds are known, $TeCl_2$ and $TeCl_4$; both have been gasified, and the formulæ of both are molecular. The chlorides are formed by the direct combination of their elements.

TELLURIUM DICHLORIDE $TeCl_2$. Mol. w. c. 196. Powdered Te is heated in a distillation-flask in a stream of Cl until the Te is completely converted into $TeCl_4$; Te is added equal in weight to the original quantity used, the whole is heated for a little time, an inverted condenser being attached to the flask, and the $TeCl_2$ is then distilled off at 320°–330° (Michaelis, *B.* 20, 2488). $TeCl_2$ is a black, amorphous solid, melting at 175° (M., *l.c.*) to a black liquid; Carnelley a. Williams give m.p. as 209° (*C. J.* 37, 125). Boils at 327° (C. a. W., *l.c.*). The vapour of $TeCl_2$ is reddish, and gives a characteristic absorption-spectrum (M., *l.c.*). V.D. at 440°, in vapour of N, = 98·2 (M., *l.c.*). The vapour becomes yellowish in presence of air or O; TeO_2 and $TeCl_4$ are formed, and after continued heating these react to produce $TeOCl_2$ (M., *l.c.*). $TeCl_2$ absorbs moisture when exposed to the air, but does not fume; on addition of much water H_2TeO_3 is formed; HClAq forms Te, and TeO_2 which remains dissolved in the acid (M., *l.c.*).

TELLURIUM TETRACHLORIDE $TeCl_4$. (*Telluric chloride.*) Mol. w. c. 269. Powdered Te is heated, in a distillation flask, in a stream of dry Cl until the solid becomes pale yellow, when it is distilled in a stream of dry CO_2 (Michaelis, *B.* 20, 1780). $TeCl_4$ is a colourless, crystalline solid, melting at 214°, and boiling without decomposition at 380° (M., *l.c.*; Carnelley a. Williams give the m.p. as 224° [*C. J.* 37, 125], and the b.p. as 414° [*C. J.* 35, 563]). V.D. 131 at 440°, 125 at 530° (M., *l.c.*). The vapour of $TeCl_4$ shows no absorption-spectrum (M., *B.* 20, 2488). $TeCl_4$ dissolves without change in dilute HClAq. It deliquesces in the air, cold water ppts. an oxychloride, and H_2TeO_3 is also formed; boiling water dissolves $TeCl_4$, and H_2TeO_3 separates on cooling.

$TeCl_4$ combines with alkali chlorides to form salts $TeCl_4.2MCl = M_2TeCl_6$; these salts are best obtained by adding MClAq to a slight excess of $TeCl_4$ dissolved in dilute HClAq and crystallising (*v.* Wheeler, *Am. S.* [3] 45, 267). The salts crystallise in regular yellow octahedra, without water. Weber (*P.* 104, 422) described a compound $TeCl_4.3AlCl_3$, obtained by melting together $TeCl_4$ and $AlCl_3$. $TeCl_4$ absorbs NH_3, forming a greenish-yellow solid that is unchanged in air and has the composition $TeCl_4.2NH_3$ (Espenschied, *A.* 113, 101).

Tellurium, fluorides of. Only one fluoride of Te has been isolated. The formula TeF_4 is probably molecular, from the analogy of $TeCl_4$.

TELLURIUM TETRAFLUORIDE TeF_4. (*Telluric fluoride.*) Prepared by dissolving H_2TeO_3 in HFAq, evaporating at 100° to a syrup, allowing to cool, separating the white nodules that are formed, and heating in a Pt basin (Högborn, *Bl.* [2] 35, 60). If carbonate or hydroxide of an alkali metal, or of Ba, is added to the solution of H_2TeO_3 in HFAq before evaporation, *double salts* of the forms $TeF_4.M^IF$ and $2TeF_4.M^{II}F_2$ are obtained; these salts are decomposed by water (H., *l.c.*).

Tellurium, haloid compounds of. These compounds belong to the forms TeX_2 and TeX_4, where X = Cl, Br or I; the only fluoride that has been isolated is TeF_4. The chlorides $TeCl_2$ and $TeCl_4$ have been gasified, and the formulæ are molecular; the formulæ of the other haloid compounds are also probably molecular. An iodide containing more I than TeI_4—perhaps TeI_6, corresponding with SI_6—may exist in the

solution of H_2TeO_3 in HIAq. No compound corresponding with S_2Cl_2, Se_2Cl_2, Se_2Br_2, and Se_2I_2 has been isolated. The haloid compounds of Te are more stable towards heat than the corresponding compounds of Se or S. The haloid compounds of Te are decomposed by water, giving H_2TeO_3 and HXAq; cold water is said to ppt. an oxychloride from $TeCl_4$. The compounds TeX_4 combine with the haloid compounds of the alkali metals to form salts M_2TeX_6; when X = F the salts are said to be of the form $MTeF_5$.

Tellurium, hydride of, TeH_2 *v.* HYDROGEN TELLURIDE, vol. ii. p. 727.

Tellurium, iodides of. Two iodides have been isolated, TeI_2 and TeI_4; a third—perhaps TeI_6—may exist in the solution of H_2TeO_3 in HIAq. TeI_2 is formed by directly combining Te and I; TeI_4 is obtained by digesting H_2TeO_3 with HIAq.

TELLURIUM DI-IODIDE TeI_2. Prepared by gently warming a mixture of powdered Te and excess of I; may be sublimed as a black, crystalline crust; when strongly heated I is given off. Not changed by water, hot or cold (Berzelius, *Lehrbuch*, 5th edit., 3, 1139).

TELLURIUM TETRA-IODIDE TeI_4. (*Telluric iodide.*) Obtained by digesting powdered H_2TeO_3 with HIAq in a closed flask, whereby hard black granules are formed. Melts when heated, and gives off I. Boiling water causes decomposition, probably forming an oxyiodide. If a solution of H_2TeO_3 in HIAq is evaporated over H_2SO_4 and CaO_2H_2 *in vacuo*, lustrous prisms are obtained that are perhaps a compound of TeI_4 and HI (B., *l.c.*). By dissolving alkali iodides in TeI_4 dissolved in dilute HIAq, and crystallising, black salts of the form M_2TeI_6 are formed in regular octahedra; the potassium salt contains $2H_2O$ and crystallises in monoclinic forms (Wheeler, *Am. S.* [3] 45, 267).

Tellurium, oxides of. Three oxides have been isolated, TeO, TeO_2, and TeO_3. TeO is probably slightly basic; TeO_2 is the anhydride of the weak acid H_2TeO_3, but it also shows feebly basic properties; TeO_3 is a very weak acidic oxide. None of the oxides has been gasified; all are known in the solid state only. An oxide of Te and S, $TeSO_3$, is also known.

TELLURIUM MONOXIDE TeO. This oxide was prepared in 1883 by Divers a. Shimosé (*C. J.* 43, 319). It is obtained by long-continued heating $TeSO_3$ to 180°-230° *in vacuo* until SO_2 ceases to be given off, powdering the residual solid, digesting it with water containing a little Na_2CO_3, washing with hot water, then with alcohol, and drying in a steam oven. TeO is a black, amorphous solid, with a slight brown shade, showing a graphitic lustre when pressed with a hard body. It is unchanged in air, but when heated it burns to TeO_2; when strongly heated *in vacuo* TeO_2 and Te are formed. TeO is scarcely affected by cold KOHAq; boiling KOHAq decomposes it, giving Te. SO_2, even if boiling, scarcely acts on TeO. The oxide dissolves in hot H_2SO_4Aq; D. a. S. say that the solution deposits $Te(SO_4)_2$ on cooling, but no analyses of the crystals that separate are given; Magnus (*P.* 10, 491) gave this formula to the product of the interaction of Te with hot conc. H_2SO_4. Heated in HCl gas $TeCl_2$ is formed. TeO is slowly reduced to Te by SO_2.

TELLURIUM DIOXIDE TeO_2. (*Tellurous oxide. Tellurous anhydride.*)

Occurrence.—As *tellurite* or *tellurium ochre*, in the Seven Mountains.

Formation.—1. Te is heated in the air.—2. By decomposing a boiling solution of $TeCl_4$ in HClAq by boiling water.—3. By heating H_2TeO_3. 4. By oxidising Te by HNO_3Aq, and heating the solution.—5. According to Hilger (*A.* 171, 211) by heating Te with H_2SO_4, SO_2 is evolved and TeO_2 separates on cooling.

Preparation.—Powdered Te is dissolved in warm HNO_3Aq, S.G. 1·25, and the solution is heated somewhat above 20°; below 8° H_2TeO_3 separates, between 8° and 20° both TeO_2 and H_2TeO_3 are formed, and the solid that forms from the solution above 20° is TeO_2 only (Klein a. Morel, *Bl.* [2] 43, 198). By allowing the solution of Te in HNO_3Aq to stand for some hours, and then adding some alcohol, TeO_2 is obtained in crystals (Oppenheim, *J. pr.* 71, 267; *cf.* Berzelius, *P.* 28, 392).

Properties. — A white, crystalline solid; melts at a red heat to a transparent, yellow liquid, which on cooling forms a white crystalline mass, giving off so much heat that the solid glows feebly. TeO_2 may be sublimed in a slow stream of air. Clarke (*Am. S.* [3] 14, 285) gives S.G. as 5·7559 at 12·5°. As obtained from a solution of Te in HNO_3Aq, TeO_2 forms quadratic octahedra; S.G. 5·65 to 5·68 at 0° (K. a. M., *l.c.*). As obtained by heating H_2TeO_3 till all water is removed and the residue melts, TeO_2 forms orthorhombic needles; S.G. 5·88 to 5·91 at 0° (K. a. M., *l.c.*). Freshly-prepared TeO_2 has no taste, but after a time it acquires a disagreeable metallic taste (Berzelius, *P.* 28, 392). It does not redden litmus paper. It is almost insoluble in water; 1 pt. dissolves in 150,000 pts. of water (K. a. M., *l.c.*). TeO_2 is very slightly soluble in most acids; it is more soluble in HClAq (*v. infra*, *Reactions*, No. 3). Dissolves readily in solutions of caustic alkalis, but in alkali carbonate solutions and in ammonia only after long-continued boiling. TeO_2 does not form H_2TeO_3 by reacting with water, but as it is obtained by heating this acid it may be called tellurous anhydride.

Reactions and Combinations.—1. Reduced to Te by heating in *hydrogen* to the temperature whereat Te vaporises.—2. Easily reduced to Te by heating with *carbon*.—3. TeO_2 absorbs *hydrogen chloride*, giving off much heat and forming compounds $TeO_2.xHCl$. At −10°, after saturation with HCl, the compound $TeO_2.3HCl$ is formed; on slightly warming HCl is given off, and $TeO_2.2HCl$ remains, and does not change when heated to 90°; on heating more strongly, $TeOCl_2$ is formed (Ditte, *A. Ch.* [5] 10, 82). *Hydrogen bromide* is also absorbed by TeO_2; by saturating TeO_2 with HBr at −15°, a black solid, resembling I, and having the composition $TeO_2.3HBr$, is formed; this compound begins to decompose at −40°, above this temperature $TeO_2.2HBr$ is produced, which remains unchanged to c. 300°, at which temperature it decomposes to $TeOBr_2$ and H_2O (D., *l.c.*). *Hydrogen iodide* and *hydrogen fluoride* are also absorbed by TeO_2, but the products have not been examined.—4. Tellurites (*q. v.*, p. 650) are formed by dissolving TeO_2 in *caustic alkali solutions*, or by fusing TeO_2 with *alkali carbonates*.—5. A compound of TeO_2 with *sulphuric anhydride* $2TeO_2.SO_3$—sometimes called basic tellurium sulphate—is formed by dissolving TeO_2 in hot H_2SO_4 diluted with 3 to 4 times its weight of water, and evaporating; it crystallises in rhombic tablets, somewhat soluble in cold dilute H_2SO_4Aq (Klein, *C. R.* 99, 326).—6. A compound with *nitric anhydride* $2(4TeO_2.N_2O_5).3H_2O$ is described by Klein a. Morel (*Bl.* [2] 43, 198), as obtained, in rhombic needles, by dissolving TeO_2 in moderately conc. HNO_3Aq, and also by dissolving Te in excess of HNO_3Aq, S.G. 1·15 to 1·35, and evaporating at a gentle heat. This compound—which is sometimes described as basic tellurium nitrate—is decomposed at c. 330°, giving off N oxides and leaving TeO_2; with much hot water it gives a pp. of TeO_2.—7. A compound, probably $TeO_2.Ag_2O.(C_4H_4O_5)_2.2aq$, is formed by dissolving TeO_2 in HBrAq, adding *tartaric acid*, and ppg. by $AgNO_3Aq$ (*v.* Brauner, *C. J.* 55, 398; *cf.* Klein a. Morel, *C. R.* 100, 1140).

TELLURIUM TRIOXIDE TeO_3. (*Telluric oxide. Telluric anhydride.*) Obtained, as an orange-yellow, crystalline mass, by heating H_2TeO_4 (*v.* TELLURIC ACID, p. 649) to somewhat above 160°. If the temperature becomes too high some of the TeO_3 is decomposed to TeO_2 and O; it is advisable, therefore, to digest the residue with cold HClAq (to remove any TeO_2), to wash out HCl by water, and to dry at 100°. TeO_3 is not changed by cold, nor by boiling, water; nor is it acted on by cold HClAq, by hot or cold HNO_3Aq, nor by dilute KOHAq. Very conc. boiling KOHAq slowly dissolves TeO_3, forming K_2TeO_4. TeO_3 dissolves in boiling HClAq, Cl is slowly given off, and H_2TeO_3 is formed in the solution (*v.* Berzelius, *P.* 28, 392). Clarke (*Am. S.* [3] 14, 286) gives S.G. of TeO_3 as 5·0704 at 14·5°.

TELLURIUM THIO-OXIDE $TeSO_3$. (*Tellurium sulphoxide. Tellurium-sulphur trioxide.*) This compound is obtained by dissolving pure Te in pure SO_3, and warming after a time to c. 30°, pouring off SO_3, and drying *in vacuo* (Weber, *J. pr.* [2] 25, 218; for description of apparatus, and details, *v.* Divers a. Shimosé, *C. J.* 43, 323). $TeSO_3$ is a red amorphous solid, melting at 30°. When pure it remains unchanged, in a sealed tube, for months (D. a. S., *l.c.*). The colour gradually changes to brown by heating to 35°; the change is instantaneous at 90°. The product, which is a brown solid, has the composition $TeSO_3$ (D. a. S., *l.c.*). At c. 180° SO_2 is given off and black TeO remains (D. a. S., *l.c.*). $TeSO_3$ is not acted on by SO_3; it dissolves in H_2SO_4Aq, giving an amethyst-red solution; water decomposes it to H_2TeO_3, TeO, Te, H_2SO_3Aq, and H_2SO_4Aq (D. a. S., *l.c.*).

$TeSO_3$ may perhaps be regarded as *tellurium sulphite*.

Tellurium, oxyacids of, H_2TeO_3, *v.* TELLUROUS ACID (p. 656); H_2TeO_4, *v.* TELLURIC ACID (p. 649).

Tellurium, oxybromide of, $TeOBr_2$. A pale-yellow solid; obtained by heating $TeO_2.2HBr$ (*v.* TELLURIUM DIOXIDE; *Reactions*, No. 8, p. 654) above 300°. Melts at red heat, forming a very dark-coloured liquid, which gives off almost black vapour with partial decomposition to TeO_2 and $TeBr_4$ (Ditte, *A. Ch.* [5] 10, 82).

Tellurium, oxychloride of, $TeOCl_2$. Prepared by heating $TeO_2.2HCl$ (*v.* TELLURIUM DIOXIDE; *Reactions*, No. 8) to above 90°. Very similar to $TeOCl_2$ (Ditte, *A. Ch.* [5] 10, 82). Decomposed at fairly high temperature to TeO_2 and $TeCl_4$.

Tellurium, oxyiodide of. According to Berzelius (*Lehrbuch* [5th edit.] 3, 1141), a greyish-brown, heavy powder is formed by digesting TeI_4 with boiling water, and this powder is probably an oxyiodide of Te; no analyses are given.

Tellurium, salts of. No compounds have been prepared by directly replacing the H of oxyacids by Te. According to Divers a. Shimosé (*C. J.* 43, 319), $Te(SO_4)_2$ is formed by dissolving TeO in hot H_2SO_4Aq and cooling, but no analyses are given; Magnus (*P.* 10, 491) gave the formula $Te(SO_4)_2$ to the product of the interaction of Te and hot conc. H_2SO_4. The compounds $2TeO_2.SO_3$ and $2(4TeO_2.N_2O_5).3aq$ are sometimes called *basic tellurium sulphate* and *basic tellurium nitrate* respectively; the compound $TeSO_3$ (*v. supra*, TELLURIUM THIO-OXIDE) may perhaps be looked on as *tellurium sulphite*; and a compound, probably $TeO_2.Ag_2O.(C_4H_4O_5)_2.2aq$, is called *tellurium-silver tartar emetic* (*v.* TELLURIUM DIOXIDE; *Reactions*, Nos. 5, 6, and 7, *supra*).

Tellurium silver tartar emetic *v.* TELLURIUM DIOXIDE; *Reactions*, No. 7, *supra*.

Tellurium, sulphides of. Berzelius (*P.* 8, 411) described two sulphides, TeS_2 and TeS_3, corresponding with the oxides TeO_2 and TeO_3. According to Becker (*A.* 180, 257), CS_2 removes almost all the S from these supposed compounds. B. concludes that the substances described by Berzelius are not definite compounds; he thinks that compounds of Te and S are probably formed by passing H_2S into TeO_2Aq and TeO_3Aq. As the substances obtained by Berzelius seem to have very definite properties, they are shortly described here.

TELLURIUM DISULPHIDE TeS_2. A dark-brown pp. formed by passing H_2S into H_2TeO_3Aq, or into an acidified solution of an alkali tellurite; softens when heated and cools to a grey, somewhat lustrous mass; gives off S when strongly heated. TeS_2 reacts as an acidic sulphide, forming compounds $xMS.TeS_2$, where M $=(NH_4)_2$, Cd, Li_2, Fe, Mg, Pb, K_2, Na_2, Zn, &c. The *thiotellurites* of the alkali metals are best obtained by saturating aqueous solutions of the tellurites with H_2S, and crystallising *in vacuo*; the thiotellurites of alkaline earth metals are formed by boiling the sulphides of these metals with TeS_2 and water; the thiotellurites of the heavy metals are obtained by ppn. from solutions of the alkali salts (Berzelius, *P.* 8, 411).

TELLURIUM TRISULPHIDE TeS_3. A blackish grey, lustrous solid; formed by saturating H_2TeO_4Aq with H_2S, and allowing to stand for some time in a closed vessel in a warm place. *Thiotellurates* of the alkali metals, $xM_2S.TeS_3$, are formed by saturating M_2TeO_4Aq with H_2S (*v.* Oppenheim, *J. pr.* 71, 267).

Tellurium, sulphoxide of, *v.* TELLURIUM THIO-OXIDE, *supra*.

Tellurium, thio-oxide of, *v. supra*.

Tellurium, thio-salts of, *v.* Tellurium disulphide, p. 655; and Tellurium trisulphide, p. 655. M. M. P. M.

TELLUROCYANIDES *v.* vol. ii. p. 853.

TELLUROUS ACID H_2TeO_3.

Formation.—1. By dissolving Te in HNO_3Aq, S.G. 1·25, and at once ppg. by water; if the solution is left for some time before adding water the pp. is TeO_2.—2. By decomposing $TeCl_4$ by cold water.

Preparation.—TeO_2 is fused with an equal weight of K_2CO_3 or Na_2CO_3 as long as CO_2 is given off; the tellurite thus formed is dissolved in water, and HNO_3Aq is added until the liquid has a very distinctly acid reaction; the flocculent pp. thus produced is allowed to remain in contact with the liquid for some hours, and is then thoroughly shaken up with the liquid, a little HNO_3Aq being added if the acid reaction disappears during this process; the pp. is then washed with ice-cold water, and dried at the ordinary temperature (Berzelius, *P.* 28, 392; *cf.* Oppenheim, *J. pr.* 71, 267). The solution of the alkali tellurite in HNO_3Aq may be decomposed by adding water, but this must be done at once, as after standing water ppts. TeO_2.

Properties and Reactions.—A white, light, amorphous solid, with a bitter, metallic taste. Reddens litmus paper. Dissolves slightly in cold water; when the aqueous solution is heated to c. 40° TeO_2 separates. When slightly heated gives TeO_2 and H_2O. H_2TeO_3 dissolves in many acids; from the solution in HClAq, water or alkalis ppts. H_2TeO_3; the solution in HNO_3Aq gives a pp. of TeO_2 on addition of water after standing for some time. From the solution in H_2SO_4Aq and HNO_3Aq the compounds $2TeO_2.SO_3$ and $2(4TeO_2.N_2O_5).3aq$ have been obtained (*v.* Tellurium dioxide; *Reactions*, No. 5 and 6, p. 655). H_2TeO_3 forms *tellurites* (*q. v.*, p. 650). Thomsen (*Th.* 2, 278) gives $[Te,O^2,H^2O] = 77,180$. M. M. P. M.

TELLURIUM, *Organic Compounds of.*

Methyl telluride Me_2Te. (82°). Formed by distilling K_2Te with $Ba(SO_4Me)_2$ (Wöhler a. Dean, *A.* 93, 233; Heeren, *Dissertation*, Göttingen, 1861). Pale-yellow, mobile, heavy oil, with persistent alliaceous smell. Oxidised by HNO_3 to $Me_2TeOHNO_3$, crystallising in prisms.—$Me_2TeHOAc$. Transparent cubes, v. sol. water. Its solution gives with HCl a pp. of Me_2TeCl_2 which crystallises in long prisms [97·5°].—Me_2TeBr_2 [89°]. Prisms.—$(Me_2Te)_2H_2CO_3$. Difficult to crystallise.—Formate $Me_2TeCH_2O_2$. Deliquescent needles.—Me_2TeI_2. Formed by heating Te with MeI at 80° (Demarçay, *Bl.* [2] 40, 100).—$(Me_2Te)_2H_2C_2O_4$.—Me_2TeO. Got from Me_2TeCl_2 and Ag_2O. Deliquescent crystalline mass, alkaline to litmus.—Me_2TeOCl_2. Got from the chloride and NH_3Aq. Short prisms (from alcohol). — $(Me_2Te)_2OBr_2$. — $(Me_2Te)_2H_2SO_4$. Cubes, v. sol. water, insol. alcohol.

Methyl-iodide Me_3TeI. Crystalline, sl. sol. water. Converted by moist Ag_2O into an alkaline base which yields $(Me_3TeCl)_2PtCl_4$.

Ethyl telluride *v.* vol. ii. p. 519.

TEMPLIN OIL. An essential oil obtained from fir cones (Flückiger, *J.* 1855, 642; Berthelot, *J. Ph.* [3] 29, 38). Colourless, becoming greenish-yellow in air. Boils at 155°–177°. S.G. ^{12} ·862. Yields on rectification a lævorotatory terpene (172°) S.G. ^{0} ·856. HNO_3 ($\frac{1}{4}$ vol.) and alcohol ($\frac{1}{8}$ vol.) yield terpin hydrate $C_{10}H_{20}O_2$ aq [118°] (250°) S. 9 at 100°. Alcohol and HCl yield crystalline $C_{10}H_{16}HCl$ and $C_{10}H_{16}2HCl$ [55°].

TERACONIC ACID $C_7H_{10}O_4$ *i.e.* $CMe_2{:}C(CO_2H).CH_2.CO_2H$. *Propylidene-succinic acid.* [163°]. Formed in small quantity by distilling the isomeric terebic acid (Geisler, *A.* 208, 50). Na and NaOEt convert terebic ether into sodium ethyl teraconate (W. Roser, *B.* 15, 293). Formed also by treatment of the ether $CO_2Et.CBrPr.CH_2.CO_2Et$ with alcoholic potash (Schleicher, *A.* 267, 130). Crystals, sol. alcohol and ether, v. sol. cold water. Above 163° it yields H_2O and an anhydride. Conc. HBrAq at 0° forms terebic acid.

Salts.—BaA''.—CaA''. Pp., v. sl. sol. water. —Ag_2A''. Needles, m. sol. water.

Mono-ethyl ether EtHA''. Oil. Decomposes Na_2CO_3, forming crystalline NaEtA'', a solution of which gives with $AgNO_3$ a pp. of the unstable AgEtA''.

Di-ethyl ether Et_2A''. (255 i.V.). Oil.

TERACRYLIC ACID $C_7H_{12}O_2$. (218° i.V.). A product of the distillation of terpenylic acid (Fittig a. Krafft, *B.* 10, 521, 1659, 1740; *A.* 208, 79; Amthor, *J. pr.* [2] 42, 389). Liquid, smelling like valeric acid, sl. sol. and lighter than water. Yields acetic acid on fusion with potash. Fuming HBr forms $C_7H_{13}BrO_2$, which gradually splits up into HBr and heptolactone $C_7H_{12}O_2$.—CaA'_2 5aq. Prisms or needles.—AgA': needles.

Ethyl ether EtA'. (191°). Fruity oil.

TERBIUM. Tr. At. w. not determined with certainty; probably c. 162 (*v. infra*).

The examination of *gadolinite*, a rare Swedish mineral, by Mosander, Cleve, and others made probable the existence therein of at least seven earths, to one of which the name terbia was given (*v.* Erbium, vol. ii. p. 456, where the history of these earths is stated more fully, with references to original memoirs). It is still very doubtful whether the substance called terbia is a homogeneous body or a mixture of more than one compound (*cf.* Metals, rare, vol. iii. p. 242). Delafontaine (*A. Ch.* [5] 14, 238) prepared an orange-yellow, earthy compound, which he regarded as pure terbia, from *samarskite*, by a long process of fractional ppn., first by K_2SO_4Aq, then by oxalic acid, and finally by formic acid (*cf.* Marignac, *A. Ch.* [5] 14, 247; Cleve, *Bl.* [2] 31, 197).

Terbia Tr_2O_3 is described as an orange-yellow amorphous solid; when heated in H for some time it becomes white. Tr_2O_3 dissolves in acids, forming salts of the type Tr_2X_3, where X = SO_4, CO_3, $2NO_3$, &c. The emission spectrum of terbia has been mapped by Roscoe a. Schuster (*C. J.* 41, 283). The at. w. of Tr—the supposed element has not been isolated—was determined by Delafontaine to be 113·5; Marignac found the value 148·5; Lecoq de Boisbaudran found 163·1, 161·4, and by later work 159·5 (*C. R.* 102, 395; 111, 474). M. M. P. M.

TEREBENE *v.* Terpenes.

TEREBENTHENE *v.* Terpenes.

DITEREBENTHYL $C_{20}H_{30}$. V.D. 4·6. (345°). S.G. ^{12} ·9688. $[\alpha]_D = 59°$. A product of distillation of colophony (Renard, *C. R.* 105, 865; 106, 856). Oil, resinified by air. $KMnO_4$ oxidises it to propionic, acetic, and formic acids and CO_2. Cold fuming HNO_3 forms $C_{20}H_{27}(NO_2)_3$, a yellow powder, sol. alcohol and ether. Br in CS_2 at −10° forms $C_{20}H_{30}Br_2$, which on heating yields diterebenthylene $C_{20}H_{28}$ (347°) S.G. ^{12} ·9821, whence Br forms $C_{20}H_{24}Br_4$. HNO_3 produces $C_{20}H_{25}(NO_2)_3$, and H_2SO_4 forms $C_{20}H_{27}SO_3H$, all amorphous solids. Bromine-water gives rise to $C_{20}H_{21}Br_8$, a brown, amorphous solid. Gaseous HCl passed into the ethereal solution forms $C_{20}H_{30}\frac{1}{2}HCl$. H_2SO_4 yields $C_{20}H_{29}SO_3H$, which is sol. water, alcohol, and ether, forming fluorescent solutions. Diterebenthyl passed through a red-hot tube forms H, C_2H_4, C_3H_6, pentane, hexane, hexylene, hexinene, heptinene, cymene, and other hydrocarbons.

TEREBENTILIC ACID $C_8H_{10}O_2$. [90°]. (250°). Got by passing the vapour of the hydrate of oil of turpentine $C_{10}H_{16}2H_2O$ over soda-lime at 400° (Personne, *A.* 100, 253; *cf.* Hempel, *A.* 180, 86). Crystalline powder, sol. hot water, v. sol. alcohol and ether. May be sublimed.—AgA′. Crystalline.

TEREBENTIC ACID $C_9H_{14}O_5$. Got by digesting oil of turpentine with oxide of lead (Weppen, *A.* 41, 294). Crystals (from alcohol).

TEREBIC ACID $C_7H_{10}O_4$ *i.e.*

$CMe_2<\begin{matrix}CH(CO_2H)\\O\text{———}CO\end{matrix}>CH_2$. Mol. w. 158. [176°]. H.C.v. 766, 642 (Ossipoff, *C. R.* 108, 812). S. (ether) 2·856 at 35° (Amthor, *J. pr.* [2] 42, 385). Formed by the action of nitric acid on oil of turpentine (Bromeis, *A.* 37, 297; Rabourdin, *J. Ph.* [3] 6, 185; Cailliot, *A. Ch.* [3] 21, 27; Svanberg a. Eckmann, *J. pr.* 66, 220; Mielck, *A.* 180, 47; Bredt, *A.* 208, 37; Erdmann, *A.* 228, 179). Formed also by oxidising pinol (Wallach, *A.* 253, 256; 259, 317). Terebic acid is perhaps identical with oxyhexic acid (Gorboff, *J. R.* 1887, 605). Monoclinic crystals (from alcohol), sl. sol. cold, v. sol. hot water. V. sol. alcohol and ether. Not attacked by fuming HNO_3. Split up by water at 150° into CO_2 and pyroterebic acid. On boiling with H_2SO_4 (2 pts.) and water (1 pt.) it is converted into the lactone of oxy-isohexoic acid  $CMe_2<\begin{matrix}CH_2\\O.CO\end{matrix}>CH_2$, CO_2 being evolved. On distillation it yields pyroterebic (hexenoic) acid, oxy-isohexoic lactone, and a little teraconic acid. On heating for 15 hours at 160° with excess of a saturated solution of baryta it is converted into acetone and succinic acid (Frost, *A.* 226, 363). Fuming HIAq yields $CH_2Pr.CH_2.CO_2H$. Alkalis form salts of diaterebic acid, of which terebic acid is the lactone.

Salts.—NH_4A': very soluble prisms.—$KA'\frac{1}{2}aq$. —$NaA'\frac{1}{2}aq$.—$BaA'_2 2aq$: amorphous. —AgA′. Prisms, v. sol. water.

Ethyl ether EtA′. (274° i.V.). S.G. ^{19} 1·111. Formed from terebic acid, alcohol, and HCl. Dilute NaOH dissolves it, forming mono-ethyl diaterebate; on cautious acidification the ether separates again, but only after warming (Ekmann). Sodium dissolves in its ethereal solution, giving off hydrogen and forming the sodium salt of acid ether of teraconic acid (*q.v.*). Alcoholic NaOEt acts in the same way, excess forming a white pp. of disodic teraconate.

Diaterebic acid
$CMe_2(OH).CH(CO_2H).CH_2.CO_2H$. The salt BaA″ 3aq is formed by boiling terebic acid with excess of baryta-water. It crystallises from alcohol, but on acidification at once yields the lactone, terebic acid. $AgNO_3$ added to a solution of the Ba salt ppts. Ag_2A''.—CaA″ 3aq.—CaA″.—PbA″ 3aq.—$Pb_3A''_2(OH)_2$ aq.

Ethyl ether Et_2A''. Formed from Ag_2A'' and EtI. Oil. Converted by acetyl chloride into $CMe_2(OAc).CH(CO_2Et).CH_2.CO_2Et$, an unstable oil.

β-Bromo-terebic acid $C_7H_9BrO_4$ *i.e.*

$CMe_2<\begin{matrix}CBr(CO_2H)\\O\text{———}CO\end{matrix}>CH_2$. [151°]. Formed by adding Br (1 mol.) to powdered teraconic acid (1 mol.) covered with water (Frost, *A.* 226, 363). Large crystals, m. sol. CS_2, v. sl. sol. chloroform and benzene. Decomposed by boiling with water into HBr and terebilic acid $C_7H_8O_4$. Reduced by sodium-amalgam to terebic acid.

References.—CHLORO- and OXY-TEREBIC ACID.

TEREBILENIC ACID $C_7H_8O_4$ *i.e.*

$CMe_2<\begin{matrix}C(CO_2H)\\O\text{---}CO\end{matrix}>CH$ (?) [169°]. Formed by heating α-chloro-terebic acid at 200° (Roser, *B.* 15, 296; *A.* 220, 261) and by evaporating β-chloro-terebic acid with water (Frost, *A.* 226, 370). Small prisms or needles (from water), v. sol. alcohol and ether. Crystallises from alcohol or conc. HBrAq in trimetric forms; $a:b:c =$ ·809:1:·858. May be sublimed. Excess of KOH forms the diaterebilenate $K_2C_7H_8O_5$, but this splits up on warming with water into KOH and potassium terebilenate. Does not combine with Br or HBr. Sodium-amalgam reduces it to terebic acid.—CaA'_2.—AgA′. Prisms.

Reference.—CHLORO-TEREBILENIC ACID.

TERECHRYSIC ACID $C_6H_8O_5$. A product of the action of HNO_3 (S.G. 1·2) on turpentine (Cailliot, *A.* 64, 376). Orange-red crystals, v. e. sol. water, alcohol, and ether.—PbA″: crystals.

TERELACTONE $C_8H_8O_2$ *i.e.* $C_5H_8<\begin{matrix}O\\CO\end{matrix}$. [12°]. (210° i.V.). Formed by the action of boiling water on di-bromo-isohexoic acid derived from pyroterebic acid and Br (Geisler, *A.* 208, 47). Mobile liquid, sol. water. Boiling baryta-water converts it into amorphous $Ba(C_6H_{11}O_3)_2$, which is sol. water and deposits $BaCO_3$ on boiling.

TEREPHTHALIC ACID $C_8H_6O_4$ *i.e.* $C_6H_4(CO_2H)_2$. *p-Phthalic acid.* Mol. w. 166. H.C.p. 770,900. H.C.v. 771,200. H.F. 188,100 (Stohmann, *J. pr.* [2] 40, 139).

Formation.—1. By the action of HNO_3 on oil of turpentine (Cailliot, *A. Ch.* [3] 21, 28; De la Rue a. Hugo Müller, *A.* 121, 86; Schreder, *B.* 7, 704; *cf.* W. C. Williams, *B.* 6, 1094).—2. By the oxidising action of chromic acid mixture on *p*-xylene (Beilstein, *A.* 133, 32; 137, 301), cuminic acid, cuminic aldehyde, cymene (Hofmann, *A.* 97, 197), *p*-toluic acid (Beilstein a. Yssel, *A.* 137, 308), di-ethyl-benzene, and amyl-toluene (Fittig, *A.* 141, 167). — 3. By the action of boiling dilute HNO_3 on cymene and on terpenes (Schwanert, *A.* 132, 257; Homeyer, *Ar. Ph.* [3] 5, 326).—4. By oxidation of *o*-ethyl-toluene by aqueous $KMnO_4$ (Claus a. Pieszcek, *B.* 19, 3083).—5. By fusing potassium *p*-sulpho-benzoate with sodium formate (Remsen, *B.* 5, 379).—6. From its nitrile, which is obtained by distilling K_4FeCy_6 with potassium benzene *p*-disulphonate (Garrick, *Z.* 1869, 551), *p*-chloro-benzene sulphonate (Nölting, *B.* 8, 1113), or *p*-

bromo-benzene sulphonate (Irelan, *Z.* 1869, 164; Barth a. Senhofer, *A.* 174, 242; Limpricht, *A.* 180, 88).—7. The semi-nitrile is also formed by the action of a hot solution of cuprous potassium cyanide upon *p*-diazobenzoic acid (Sandmeyer, *B.* 18, 1497).—8. By heating *p*-di-bromo-benzene with chloroformic ether and 1 p.c. sodium-amalgam at 110° and saponifying the product (Bonz, *B.* 18, 2305).—9. By the action of 5 p.c. $KMnO_4$ on an oil (258°–263°) which remains as a residue in the manufacture of aniline and toluidine (Hell a. Rockenbach, *B.* 22, 505).

Preparation.—1. Br (2 mols.) is added to boiling *p*-xylene (100 g.), and the resulting $C_6H_4(CH_2Br)_2$ decomposed by alcoholic KOAc on the water-bath. After evaporating the alcohol the $C_6H_4(OAc)_2$ is extracted with ether, and oxidised by adding 4·5 litres of 10 p.c. $KMnO_4$ to its solution in water (1 litre) and NaOH (500 g. of S.G. 1·22). Finally more $KMnO_4$ is added till the solution remains violet, the solution kept at 100° for 3 hours, filtered, and ppd. by HCl (Baeyer, *A.* 245, 139).—2. By oxidising *p*-xylene with chromic acid mixture (Beilstein, *A.* 133, 41). 3. From *p*-toluidine by Sandmeyer's reaction, the resulting *p*-toluic acid being oxidised by $KMnO_4$ (Baeyer a. Herb, *A.* 258, 1).

Properties.—White crystalline powder, nearly insol. water, alcohol, ether, chloroform, and HOAc. Sublimes without previous fusion. Does not yield an anilide on boiling with aniline (Michael a. Palmer, *B.* 19, 1376). It is ppd. from its salts by phthalic acid. Yields benzene when distilled with slaked lime. Reduced by sodium-amalgam in a current of CO_2 to the $\Delta^{2,5}$ or (1,4)- dihydride. If CO_2 be not used the product is the $\Delta^{1,4}$ or (3, 6)- dihydride, which is also got by boiling the (1,4)-dihydride with NaOHAq (Baeyer, *A.* 269, 153; *cf.* Mohs, *Z.* [2] 3, 68). The (1,4)-dihydride gives benzoic acid on oxidation by MnO_2 and dilute H_2SO_4, while the (3,6)-dihydride forms terephthalic acid (Baeyer, *A.* 269, 182). By heating its alkaline solution with sodium-amalgam terephthalic acid is reduced to a tetrahydride, and this is further reduced by HIAq at 240° to a hexahydride (Baeyer, *B.* 19, 1805).

Salts. — $(NH_4)_2A''$. Small crystals. — CaA'' 3aq. S. ·08 at 6°.—BaA'' 4aq. S. ·28 at 5°.—SrA''. S. ·19 at 17°.—Ag_2A''. Curdy pp.

Mono-methyl ether $MeHA''$. [c. 230°]. Formed by the action of conc. H_2SO_4 or alcoholic potash on the di-methyl ether (Baeyer, *A.* 245, 141). Needles, sol. Na_2CO_3Aq and hot water.

Di-methyl ether Me_2A''. [140°]. S. ·3 at 100°. H.F. 172,300 (Stohmann, *J. pr.* [2] 43, 2). Formed by heating the acid with PCl_5 on the water-bath and pouring the product into methyl alcohol. Trimetric plates; $a:b:c$ = ·843:1:3·083. Insol. cold water, sl. sol. hot MeOH, m. sol. EtOH.

Di-ethyl ether Et_2A''. [44°]. Prisms.

Propyl ether Pr_2A''. [31°]. Needles.

Isopropyl ether Pr_2A''. [56°]. Plates.

n-Butyl ether $(C_4H_9)_2A''$. Liquid.

Isobutyl ether $(CH_2Pr)_2A''$. [52·5°]. Needles, v. sol. ether (Berger, *B.* 10, 1742).

Isoamyl ether $(C_5H_{11})_2A''$. Pearly scales.

Phenyl ether Ph_2A''. [194°] (Baeyer, *A.* 258, 44). Formed from the chloride and phenol. Leaflets.

Chloride $C_6H_4(COCl)_2$. [78°]. (259°).

Amic acid $C_6H_4(CONH_2).CO_2H$. [214°]. Formed from *p*-diazo-benzoic acid by Sandmeyer's reaction (Sandmeyer, *B.* 18, 1498). Minute plates (from water), m. sol. cold water.

Amide $C_6H_4(CONH_2)_2$. Formed from the chloride and NH_3Aq. Amorphous.

Nitrile $C_6H_4(CN)_2$. [220°] (Luckenbach, *B.* 17, 1428). Formed from the amide and P_2O_5. Got also by distilling calcium bromo-benzene *p*-sulphonate with K_4FeCy_6. Conc. HIAq forms $C_6H_4(CI_2.NH_2)_2$ (Biltz, *B.* 25, 2543).

Γ *cistrans* $\Delta^{2,5}$ or (1,4)- **Dihydride**

$CO_2H.CH\left<\begin{matrix}CH{:}CH\\CH{:}CH\end{matrix}\right>CH.CO_2H$. S. ·3 in the cold. H.F. 182,600 (Stohmann, *J. pr.* [2] 43, 538). Formed by reducing terephthalic acid in a current of CO_2 by sodium-amalgam (Baeyer, *A.* 251, 257; 269, 153). Monoclinic prisms (from EtOAc); $a:b:c$ = ·982:1:1·019; β = 78° 2′. M. sol. ether. Not attacked by sodium-amalgam in the cold. Unites with bromine (4 atoms). Transformed into the $\Delta^{1,5}$ isomeride by boiling with water, and into the $\Delta^{1,4}$ acid by boiling with NaOHAq. Alkaline $KMnO_4$ re-oxidises the acid to terephthalic acid. A warm solution of the acid readily reduces $AgNO_3$. On warming with aqueous cupric acetate it gives off CO_2 and forms a white pp. which, on adding HOAc and warming, yields Cu_2O, the liquid then containing benzoic acid. The (3,6), (3,4), and (2,3) isomerides do not reduce $AgNO_3$ and cupric acetate. The Ba salt crystallises in plates, and is v. sol. water.

Methyl ether Me_2A''. [77°]. Yields a di- and a tetra-bromide. Br in $CHCl_3$ forms a dibromide [170°] and a tetrabromide [98°].

Di-phenyl ether Ph_2A''. [146°]. Formed from the chloride and phenol at 100°. Small crystals, sl. sol. alcohol, ether, and ligroïn.

Γ *cis* $\Delta^{2,5}$ or (1,4)- *Dihydride*

$CO_2H.CH\left<\begin{matrix}CH{:}CH\\CH{:}CH\end{matrix}\right>C(CO_2H)H$. Extracted by ether from the mother-liquor from which the preceding isomeride has separated. Closely resembles its *cistrans* isomeride, but the *cis* acid and its salts are the more soluble.

$\Delta^{1,5}$ or (3,4)- **Dihydride**

$CO_2H.CH\left<\begin{matrix}CH{:}CH\\CH_2.CH\end{matrix}\right>C.CO_2H$. S. ·042 in the cold. H.F. 185,300. Formed by boiling the (1,4)- dihydride with water, and obtained, therefore, by reducing terephthalic acid with sodium-amalgam (Baeyer, *A.* 245, 142; 251, 257; 269, 148). Converted into the (3,6)- acid by NaOHAq. Sodium-amalgam in the cold reduces it to the Δ^2 tetrahydride.—BaA'' 4aq. Trimetric crystals; $a:b:c$ = ·319:1: ·352 (Baeyer a. Herb, *A.* 258, 22).

Methyl ether Me_2A''. [40°].

$\Delta^{1,4}$ or (3,6)- **Dihydride**

$CO_2H.C\left<\begin{matrix}CH_2.CH\\CH\ .CH_2\end{matrix}\right>C.CO_2H$. S. ·0059 in the cold. H.F. 191,900. Formed by reduction of terephthalic acid in alkaline solution by sodium-amalgam (Baeyer, *A.* 245, 142). Got also by boiling the (1,4)- dihydride with NaOHAq. Slender needles (from water), almost insol. ether. Much resembles terephthalic acid. On sublimation it is partially converted into terephthalic

acid. Immediately oxidised by $KMnO_4$. Forms  $CH(CO_2H)<\substack{CH_2.CHBr\\CHBr.CH_2}>CH.CO_2H$ by uniting with HBr. Sodium-amalgam in the cold reduces it to a slight extent, forming the two isomeric Δ^2 tetrahydrides.—BaA″4aq. Crystals, resembling its $\Delta^{1,5}$ and $\Delta^{1,3}$ isomerides.

Mono-methyl ether MeHA″. [225°]. Got from Me_2A'' and alcoholic potash. Needles (from hot water).

Di-methyl ether Me_2A''. [130°]. H.F. 172,700. Formed from the dihydride by successive treatment with PCl_5 (2 mols.) and MeOH. Monoclinic plates (from EtOAc); $a:b:c = 1{\cdot}52:1:2{\cdot}79$; $\beta = c.\ 74°$. Sl. sol. water, m. sol. hot alcohol, v. e. sol. ether. Br in $CHCl_3$ yields a dibromide $C_6H_6Br_2(CO_2Me)_2$ [90°] and a tetrabromide [150°]. Excess of Br yields  $CO_2Me.C_6H_6Br<\substack{CO\\O}$ [188°]. HBr forms $C_6H_8Br_2(CO_2H)_2$ which yields $C_6H_8Br_2(CO_2Me)_2$ [166°].

Di-phenyl ether Ph_2A''. [191°]. Formed by treating the chloride with phenol (Baeyer a. Herb, *A.* 258, 31). Small scales (from hot MeOH), sl. sol. ether.

$\Delta^{1,3}$ or (5,6)- **Dihydride**

 $CO_2H.C<\substack{CH_2.CH_2\\CH:CH}>C.CO_2H$. S. ·0053 in the cold. Formed by the action of alcoholic potash on the dibromide of the Δ^2 tetrahydride and on the tetrahydride of di-bromo-terephthalic acid got by bromination of the hexahydride. Unites with hydrogen bromide (2 mols.) forming  $CO_2H.CH<\substack{CH_2.CH_2\\CHBr.CHBr}>CH.CO_2H$. Easily reduced by Zn and HOAc and by sodium-amalgam to the two Δ^2 tetrahydrides. Boiling water converts it into the (3,4)- isomeride. Boiling NaOHAq forms the (3,6)- isomeride.—BaA″ 4aq. Needles (from hot water).

Methyl ether Me_2A''. [85°]. Monoclinic plates; $a:b:c = 2{\cdot}241:1:3{\cdot}591$; $\beta - 87°\ 13'$. Slowly converted by HBr into (2,3)-di-bromo-terephthalic acid hexahydride, which is reduced by zinc-dust and acetic acid to the Δ^2 tetrahydride of terephthalic acid. Yields a dibromide [64°].

Di-phenyl ether Ph_2A''. [175°]. Large needles (from MeOH), sl. sol. cold alcohol.

Δ^1 or (3,4,5,6)- **Tetrahydride.**

 $CH(CO_2H)<\substack{CH_2.CH\\CH_2.CH_2}>C.CO_2H$. [above 300°]. S. ·102 at 16°; ·83 at 100°. H.F. 214,200 (Stohmann, *J. pr.* [2] 43, 5). Formed by boiling a solution of terephthalic acid (1 pt.) in NaOHAq for twenty hours with gradual addition of 4 p.c. sodium-amalgam (100 pts.) (Baeyer, *B.* 19, 1805; *A.* 245, 160; 258, 32). Prisms, more sol. water than terephthalic acid or its dihydrides. Combines with HBr and with Br (1 mol.). Immediately reduces alkaline $KMnO_4$, yielding oxalic acid.—BaA″ 3½aq. M. sol. cold water. Reduced by HIAq at 240° to the hexahydride.—Ag_2A''. Amorphous.

Methyl ether Me_2A''. [39°]. H.F. 196,200. Plates. Its ethereal solution shows blue fluorescence and gives a fugitive rose-red pp. with NaOEt. HBr gives $C_6H_8Br(CO_2H)_2$, whence Me_2A'' [95°]. Bromine forms $C_6H_8Br_2(CO_2Me)_2$ [81°].

Di-phenyl-ether Ph_2A''. [145°]. Formed from the acid by successive treatment with PCl_5 and phenol. Monoclinic crystals; $a:b:c = 2{\cdot}824:1:2{\cdot}470$, m. sol. cold alcohol and ether.

Γ *cistrans* Δ^2 or (1,4,5,6)- **Tetrahydride**

 $CH(CO_2H)<\substack{CH_2.CH_2\\CH:CH}>CH.CO_2H$. [c. 220°]. S. ·17. Formed by reducing $\Delta^{1,5}$ dihydride and also the dibromide of the $\Delta^{1,3}$ dihydride. Oxidised by $KMnO_4$ in the cold to succinic acid and a soluble acid [150°]. Alkaline K_3FeCy_6 gives terephthalic acid. Yields three dibromides  $CH(CO_2H)<\substack{CH_2.CH_2\\CHBr.CHBr}>CH.CO_2H$. [171°], [51°], and [94°]. The Ba and Cd salts are more sol. water than those of the Δ^1 isomeride.

Methyl ether Me_2A''. [c. 3°].

Amide. Dimetric needles; $a:c = 1:2{\cdot}151$.

Diphenyl ether Ph_2A''. Formed, in two modifications [107°] and [c. 190°] by the successive action of PCl_5 and phenol (Baeyer a. Herb, *A.* 258, 39). The modification [c. 190°] probably is a mixture containing the Δ^1 isomeride.

Dibenzyl ether $(C_7H_7)_2A''$. [48°]. From Ag_2A'' and benzyl chloride.

Γ *cis* Δ^2 or (1,4,5,6)- **Tetrahydride.** [150°–155°]. S. 2·7 in the cold. Formed, together with the *cistrans* isomeride, by reducing the $\Delta^{1,4}$ dihydride by sodium-amalgam in the cold. The Ba, Cd, and Ag salts are amorphous. This acid and the *cistrans* isomeride are converted into the Δ^1 isomeride by boiling with NaOHAq.

Γ *cistrans* **Hexahydride**

 $CO_2H.CH<\substack{CH_2.CH_2\\CH_2.CH_2}>CH.CO_2H$. *Fumaroid or stable modification.* [300°]. S. ·086 at 16°; 1·3 at 100°. H.F. 236,500 (Stohmann, *J. pr.* [2] 43, 7). Formed by heating the tetrahydride with HIAq for 6 hours at about 240° (Baeyer, *B.* 19, 1806; 245, 170; 251, 257). Formed also by heating ethyl butane tetracarboxylate with NaOEt and ethylene bromide at 100°; the product being hydrolysed and heated at 220° till evolution of CO_2 ceases (Mackenzie a. Perkin, jun., *C. J.* 61, 174). Prepared by reducing the hexahydride of bromo-terephthalic acid with zinc-dust and HOAc. Small prisms, sol. hot water. May be sublimed. Not oxidised by cold alkaline $KMnO_4$. Br (2 mols. at 100°) forms $C_6H_9Br(CO_2H)_2$ [71°], and a maleic isomeride [205°]. Treatment with PCl_5 followed by Br at 150° forms $C_6H_8Br_2(CO_2H)_2$ in a fumaroid modification which yields Me_2A'' [150°] and a maleic modification which yields Me_2A'' [68°] and an anilide [200°]. The K and Ba salts are v. sol. water; the Ca salt is sl. sol. water.

Methyl ether Me_2A''. [71°]. S. ·5 at 100°. H.F. 218,100. Exhibits no fluorescence. Volatile with steam.

Diphenyl ether Ph_2A''. [151°]. Needles.

Γ *cis* **Hexahydride**

 $CO_2H.CH<\substack{CH_2.CH_2\\CH_2.CH_2}>C(CO_2H)H$. *Maleic or labile modification.* [162°]. H.F. 237,400. Formed by reducing the very soluble hexahydride of bromo-terephthalic acid with zinc-dust and HOAc. Plates (from water), v. sol. alcohol and ether. Changes on heating with HClAq at 180° into its isomeride. Its Ba salt and methyl ether do not crystallise.

References.—Bromo-, Chloro-, Nitro-, and Oxy- terephthalic acid.

TEREPHTHALIC ALDEHYDE $C_6H_4(CHO)_2$[1:4]. [116°]. (247°). S. 1·7 at 100°. Formed by boiling $C_6H_4(CH_2Cl)_2$ or $C_6H_4(CH_2Br)_2$ (1 pt.) with lead nitrate (1 pt.) and water (20 pts.) (Grimaux, *C. R.* 83, 825; Löw, *A.* 231, 363). Formed also by the action of fuming HNO_3 on di-ω-bromo-*p*-xylene (Löw, *B.* 18, 2072), and by boiling $C_6H_4(CHCl_2)_2$ with water (Colson a. Gautier, *Bl.* [2] 45, 6, 508). Obtained from $CH_2(OH).C_6H_4.CH_2OEt$ by successive treatment with PCl_5 and water (Colson, *Bl.* [2] 42, 152).

Preparation.—*p*-Xylene (1 pt.) is heated with Br (6 pts.) at 140° to 200° with inverted condenser. The crystalline tetra-ω-bromo-xylene [169°] thus obtained is heated with three times its weight of H_2SO_4 (S.G. 1·825 at 120°–130°), the product poured into water, and the needles that separate recrystallised from water (Hönig, *M.* 9, 1153).

Properties.—Long needles, v. sl. sol. hot water and cold ether, v. sol. alcohol. Slightly volatile with steam. Dissolves in 25 pts. of saturated aqueous $NaHSO_3$ at 45°.

Reactions.—1. Oxidised by *chromic acid mixture* to *p*-aldehydo-benzoic acid and then to terephthalic acid.—2. Conc. NaOHAq forms terephthalic acid, ω-oxy-toluic acid, and di-ω-oxy-xylene.—3. KNO_3 and excess of H_2SO_4 at 110° form nitro-terephthalic aldehyde.—4. Cold conc. NH_3Aq forms tri-*p*-aldehydo-hydrobenzamide $(C_6H_4(CHO).CH)_3N_2$, a crystalline powder, insol. water, alcohol, and ether, yielding on oxidation by $KMnO_4$ crystalline $N_2(CH.C_6H_4.CO_2H)_3$ (Oppenheimer, *B.* 19, 574).—5. Dry or alcoholic NH_3 forms crystalline $C_6H_4(CH:NH)_2$.—6. NaOAc and Ac_2O give *p*-aldehydo-cinnamic acid.—7. *Acetone* and dilute NaOH give a white pp. of $C_6H_4(CH:CH.CO.CH_3)_2$, which crystallises from ether-acetone in matted needles [156°], insol. water and alcohol, and gives a deep-red solution in conc. H_2SO_4. An intermediate body is $C_6H_4(CH(OH).CH_2.CO.CH_3)_2$.—8. $NPhMe_2$ and $ZnCl_2$ form $C_6H_4(CHO).CH(C_6H_4NMe_2)_2$, the leuco derivative of the aldehyde of malachite green.—9. Cold conc. aqueous KCy added to a cold saturated alcoholic solution of the aldehyde ppts. amorphous $C_{16}H_{12}O_4$, which probably has the formula $C_6H_4(CHO).CH(OH).CO.C_6H_4(CHO)$ [170°–174°]. This body reduces cold ammoniacal $AgNO_3$, forming a mirror. It also reduces warm Fehling's solution and combines with phenyl-hydrazine. $KMnO_4$ oxidises it to benzoin di-*p*-carboxylic acid. NaOHAq dissolves it, forming benzoïn di-*p*-carboxylic acid, di-ω-oxy-*p*-xylene, and other bodies (Oppenheimer, *B.* 19, 1814).

Phenyl-hydrazide [230°].

Oxim $C_6H_4(CH:NOH)_2$. [200°]. Formed from the aldehyde and an alkaline solution of hydroxylamine (Westenberger, *B.* 16, 2994). Crystalline, v. sol. alcohol and ether, sl. sol. water. Yields $C_6H_4(CH:NOEt)_2$ [55°] and $C_6H_4(CH:NOAc)_2$ [155°].

Reference.—NITRO-TEREPHTHALIC ALDEHYDE.

TEREPHTHALIC AMIDINE $C_8H_{10}N_4$ *i.e.* $C_6H_4(C(NH).NH_2)_2$. The salt B″2HCl, formed by digesting terephthalic imido-ethyl ether with alcoholic NH_3, is crystalline, and yields $B''H_2PtCl_6$ (Luckenbach, *B.* 17, 1436).

TEREPHTHALOPHENONE *v.* **PHTHALOPHENONE.**

TERPENES $C_{10}H_{16}$; also **Sesquiterpenes** $C_{15}H_{24}$ and **Polyterpenes** $(C_{10}H_{16})_n$. The greater number of these hydrocarbons exist ready formed as constituents of essential oils secreted by plants. Others are produced from the natural terpenes by the action of heat or of chemical agents. A dihydrocymene isomeric with the natural terpenes has been obtained synthetically from methyl-isopropyl succino-succinic ester and the homologous dihydroparaxylene and dihydrobenzene by corresponding processes (Baeyer, *B.* 25, 1840, 2122; 26, 232). The natural terpenes are generally optically active liquids, with right- or left-handed rotatory power. The only exception is the racemic compound dipentene (*q. v.*). The following isomerides are known:—

1. **Pinene.** This includes two varieties, australene or dextropinene and terebenthene or lævopinene. American spirit of turpentine consists chiefly of dextropinene. (156°). $[\alpha]_j = +21{\cdot}5$ (Berthelot, *A.* 83, 105; 88, 345, 110, 367, *Suppl.* ii. 226). S.G. $\frac{0}{4} = {\cdot}8765$; $\frac{25}{25} = {\cdot}8586$; $\frac{100}{100} = {\cdot}8278$ (Tilden, *unpubl. expts.*). French turpentine oil consists almost wholly of lævopinene. (156·5°). $[\alpha]_j = -40{\cdot}32$. S.G. $\frac{0}{0} = {\cdot}8767$; $\frac{17{\cdot}88}{17{\cdot}88} = {\cdot}8619$ (Riban, *C. R.* 78, 788; 79, 314). It is also present in oil of rosemary (Bruylants, *J.* 1879, 944), oil of lemon (Tilden, *Ph.* [3] 9, 654), sage and juniper (*C. J.* 31, 554), thyme and anise (Brühl, *B.* 21, 156), and other essential oils.

For production and properties of turpentine oils *v.* OILS, ESSENTIAL, Thorpe's DICTIONARY OF APPLIED CHEMISTRY.

Different specimens of the pinenes, both dextro- and lævo-, obtained by fractional distillation from turpentine exhibit considerable variations in their rotatory power. An optically inactive liquid has been obtained by Wallach (*A.* 258, 343) from pinene nitrosochloride by treatment with aniline, whereby a diazo-compound is formed, which with the neighbouring chlorine atom gives rise to diazobenzenechloride and regenerates the hydrocarbon

$$-CCl-C.NO- + H_2NC_6H_5 = -CCl-C(N:NC_6H_5)- + H_2O \text{ and}$$

$$-CCl-C(N:NC_6H_5)- = -C{=}C- + ClN_2C_6H_5.$$

The hydrocarbon thus obtained boils at 155°–156°, has a density ·858 at 20°, a refractive index for D 1·46553 at 21°, and is supposed to be identical in constitution with the pinenes. It is apparently not resolvable into a mixture of dextro- and lævo- pinenes, but with nitrosyl chloride and other reagents it behaves in the same manner as pinene.

Dry pinene unites with one molecule of dry hydrogen chloride, forming a crystalline compound formerly called artificial camphor [125°], which appears quite saturated, as it is unacted upon either by excess of hydrogen chloride or bromine. The hydrochloride prepared from dextropinene is dextrorotatory, while that from lævopinene is lævorotatory. The compound is very stable; it may be distilled almost without change, mere traces of hydrogen chloride being evolved; and it is unacted upon by aqueous solutions of the alkalis, except at high temperatures under pressure. Heated with sodium stearate, benzoate, or acetate, or with alcoholic potash, it loses the elements of hydrogen chloride and yields solid camphene (*v.* CAMPHENE, *infra*). In the presence of water, alcohol, ether, or acetic acid, pinene takes up two mols. of hydrogen chloride, producing a compound of different character [50°], which on the application of heat is readily split up into hydrogen chloride and a mixture of liquid hydrocarbons (*v.* DIPENTENE, *infra*). Nitrosyl chloride passed into a solution of pinene in chloroform at −10° yields a compound $C_{10}H_{16}NOCl$ [103°], which is ppd. as a white crystalline powder on the addition of alcohol (Tilden, *C. J.*, June 1875). The same compound is formed by adding hydrochloric acid to a cooled mixture of the terpene with amyl nitrite and glacial acetic acid (Wallach, *A.* 245, 245). The nitrosochloride gently heated with alcoholic potash yields a nitroso- compound, $C_{10}H_{15}NO$ [129°] (Tilden). For crystallography *v.* Story-Maskelyne (*C. J.*, June 1875, and *Phil. Mag.*). Nitrosopinene unites with two atoms of bromine, forming a crystalline dibromide, which decomposes on melting [132°]. Mixed with alcohol and nitric acid both pinenes form crystallised terpin hydrate $C_{10}H_{18}(OH)_2.OH_2$ (Wiggers, *A.* 33, 358; 57, 247; Tilden, *C. J.* 33, 217; Hempel, *A.* 180, 71). Pinene dissolved in carbon tetrachloride and mixed with bromine yields a mixture of products, from which a well-defined crystalline dibromide $C_{10}H_{16}Br_2$ [169°–170°] may be isolated. On heating this with aniline it gives up hydrogen bromide, and ordinary cymene is produced. The yield, however, amounts only to about 10 p.c. of the bromide employed (Wallach, *A.* 264, 1). Exposed to the action of air or oxygen, in sunlight, the pinenes produce a crystalline compound $C_{10}H_{18}O_2$ (Sobrero, *C. R.* 33, 66) which when distilled with dilute acid yields a compound called by Armstrong 'Sobrerone' (Armstrong a. Pope, *C. J.* 59, 311), which is identical with one of the products of the action of nitrous acid on pinene, isolated by Wallach a. Otto, and called by them 'Pinol' (*A.* 253, 249). Pinene distilled with bleaching powder and water yields a large quantity of chloroform. Picric acid has no action upon pinenes in the cold, but at the b.p. of the latter a brisk reaction sets in, and if the liquid is afterwards allowed to cool a compound is deposited in colourless scales, which on boiling with alkali yield borneol (Lextreit, *C. R.* 102, 555; Tilden a. Forster, *C. J.* 63, 1388).

2. Limonene. This compound, like pinene, occurs in two optically active varieties. Dextro-limonene (175°–176°), S.G. $\frac{20}{20}$ ·846, $[\alpha]_D = +106{\cdot}8$ (Wallach, *A.* 252, 145) occurs in oils of the fruit of oranges and lemons, also in caraway and dill, &c. The most convenient source is the essential oil of sweet orange, *Citrus aurantium*. Lævo-limonene is obtained from the oil distilled from the leaves of *Pinus sylvestris* and *P. picea.* This oil occurs in the drug houses as 'Fir-Wool oil,' but is now much adulterated with common turpentine, and the commercial oil seldom yields more than a small percentage of limonene. (175°–176°), S.G. $\frac{20}{20}$ = ·846, $[\alpha]_D = -105°$ (Wallach, *A.* 227, 287, 246, 221). The limonenes, treated with perfectly dry hydrogen chloride, yield a liquid monochloride. In the presence of alcohol they give, with excess of hydrogen chloride, a quantitative yield of a dihydrochloride [50°], identical with the compound obtained from the pinenes. By the action of nitrosyl chloride (Tilden a. Shenstone, *C. J.* May, 1877), or by the use of amyl or ethyl nitrite and hydrogen chloride (Wallach), they yield a crystalline nitrosochloride, which, whether formed from dextro- or lævo-limonene, is always a mixture of two isomerides separable from each other by cold chloroform or ether. There are therefore four isomeric limonene nitroso-chlorides, as follows:

FROM *d.* LIMONENE:
α compound [103°–104°] $\alpha_D = +313°$
β ,, [105°–106°] $\alpha_D = +240°$
FROM *l.* LIMONENE:
α compound [103°–104°] $\alpha_D = -314°$
β ,, [100°] $\alpha_D = -242°$

From the nitroso-chlorides by the action of heat (Tilden a. Shenstone), or by boiling with alcohol (Goldschmidt a. Zürrer, *B.* 18, 2220), is produced an isonitroso-limonene, which when made from lævo-limonene is identical in every respect with carvoxim $C_{10}H_{14}N.OH$, from carvol, extracted from oil of caraway (Goldschmidt a. Zürrer, *B.* 18, 1732). For a comparison of the rotatory powers of the two limonenes and their derivatives, see Wallach (*A.* 252, 141). The limonenes are further characterised by the formation of a crystalline tetrabromide [104°–105°] by direct addition of bromine (Wallach, *A.* 227, 277).

By mixing together equal quantities of dextro- and lævo- limonenes an optically inactive mixture is obtained, which behaves in many respects as a distinct hydrocarbon, and appears to be identical with dipentene (*q. v.*). Strong sulphuric acid acting upon citrene (*d*-limonene), causes polymerisation, the chief product being a colophene (310°–320°) (Bouchardat a. Lafont, *C. R.* 115, 1083).

The oil of *Licari kanali* contains a compound, licareol $C_{10}H_{18}O$, from which a hydrocarbon, licarene $C_{10}H_{16}$, is obtainable by the action of acetic anhydride at 150° (Barbier, *C. R.* 114, 674, and *C. R.* 116, 993, and 1062). This terpene appears to consist of impure *d*-limonene, as it boils at 176°–178°, gives a tetrabromide [103°–104°], forms a nitrosochloride, from which carvoxim [72°] is formed by alcoholic potash; but its specific rotatory power is low, $[\alpha]_D = 7{\cdot}51°$.

3. Sylvestrene occurs in Swedish turpentine (Atterberg, *B.* 10, 1206) and in Russian turpentine (Wallach, *A.* 230, 245), in company with australene and other hydrocarbons of higher boiling-point. (176°–177°). S.G. $\frac{18}{18}$ = ·8510; $\frac{20}{20}$ = ·8470. $[\alpha]_D = +66{\cdot}32$ (Wallach, *A.* 245, 197). The odour of sylvestrene differs from that of pinene and limonene, and resembles the odour of fresh firwood. It forms a liquid monohydrochloride, and a crystalline dihydrochloride [72°], from which the hydrocarbon may be recovered unchanged by heating with aniline. Sylvestrene also gives a nitrosochloride [106°–107°], which, by treatment with alcoholic potash, yields only oily products. The tetrabromide crystallises in monoclinic tables [135°] (Wallach, *A.* 239, 29).

4. Phellandrene. The seeds of *Phellandrium aquaticum* were found by Pesci (*G.* 16, 225) to yield about 2½ p.c. of a volatile oil, consisting chiefly of a dextrorotatory terpene (171°–172°). The same hydrocarbon is contained in the oil of bitter fennel, *Fœniculum vulgare* (Wallach, *A.*

239, 40), and in the oil of elemi. Lævo-phellandrene is found, according to Wallach (*A.* 246, 232), in the oil of *Eucalyptus amygdalina.* Phellandrene is characterised by the formation of a nitroso-nitrite $C_{10}H_{16}N_2O_3$. Pesci obtains it by the action of a nitrite and dilute sulphuric acid upon the hydrocarbon. It crystallises in needles [94°], and although obtained from the dextrorotatory hydrocarbon it rotates the plane of polarisation to the left. $[\alpha]_D = -183{\cdot}5°$ (Pesci). By reducing agents this compound is converted into a base $C_{10}H_{16}(NH_2)_2$ (209°–214°). Ammonia converts it into nitrophellandrene $C_{10}H_{15}NO_2$ and an acid.

5. **Dipentene**, formerly called terpilene or terpinylene. As already stated, this compound is produced when equal quantities of dextro- and lævo- limonenes are mixed together (see *Pentylenes*). It is formed by heating isoprene to a temperature of about 300°. It is also the chief constituent of 'isoterebenthene,' formed by the action of heat on lævo-pinene. It occurs among the products of the destructive distillation of caoutchouc. Dipentene is also produced, together with terpinene, terpinolene, and terpineol, by the action of sulphuric acid or phosphoric acid on terpin, or by the action of sulphuric acid on the pinenes under certain conditions (Armstrong a. Tilden, *C. J.* November, 1879). It is also formed from the dihydrochloride [50°], whether made from pinene or limonene, either by the action of heat upon the chloride alone (Tilden, *B.* 12, 1133) or by boiling it with a mixture of sodium acetate and acetic acid, or with alcohol and aniline (Wallach). The products thus obtained were formerly supposed to consist of a single hydrocarbon, to which the name 'terpilene' was given. The hydrocarbons known as cinene and cajeputene formed from cineol and cajeputol respectively also consist of dipentene. Dipentene occurs ready formed in the volatile oil of the camphor tree, also in oil of elemi and in Russian and Swedish turpentines (Wallach, *A.* 227, 296, &c.).

Dipentene boils at about 176°, and has a pleasant smell of lemons. It combines with bromine forming a tetrabromide [124°], and unites with 2HCl forming a chloride [50°], from which it may be regenerated by methods given above. It is to be noted, however, that in all cases more or less isomeric change occurs, and the hydrocarbon, whether reproduced by heat alone or by the action of aniline, always contains terpinene and terpinolene, beside cymene and a small quantity of a paraffinoid hydrocarbon (Tilden a. Williamson, *C. J.* 63, 292). The nitrosochloride $C_{10}H_{16}NOCl$ yields an inactive carvoxim $C_{10}H_{14}NOH$ [93°] (*A.* 245, 267). A mixture of equal volumes of dextro- and lævo-limonene behaves in many respects as though it were a distinct hydrocarbon, as it was supposed to be previously to Wallach's researches. Thus the tetrabromide melts at 124°, while the limonene compound melts at 104°. The inactive isonitrosodipentene or carvoxim, melting at 93°, is formed by mixing together equal quantities of lævo-carvoxim [72°] from dextro-limonene and dextro-carvoxim [72°] from lævo-limonene. The resulting compound gives, by Raoult's freezing-point method, a molecular weight corresponding to the simple formula $C_{10}H_{15}NO$ (Wallach, *A.* 246, 230).

Certain derivatives of dipentene exist in two optically inactive forms. When *d*-limonene-nitrosochloride, prepared from either dextro- or lævo-limonene, is warmed with an alcoholic solution of piperidine, a mixture of two crystallisable nitrolamines is formed in each case, as follows:

NITROLPIPERIDINES $C_{10}H_{16}NONC_5H_{10}$, FROM LÆVOLIMONENE:

(α) [93°–94°] Rhombic, from alcohol. $[\alpha]_D = -67{\cdot}60°$. Hydrochloride dextrorotatory.
(β) [110°–111°]. Monoclinic. $[\alpha]_D = +60{\cdot}18°$. Hydrochloride almost inactive.

FROM DEXTROLIMONENE:

(α) [93°–94°]. Rhombic. $[\alpha]_D = +67{\cdot}95°$. Hydrochloride lævorotatory.
(β) [110°–111°]. Monoclinic. $[\alpha]_D = -60{\cdot}48°$. Hydrochloride (?).

When the two α-piperidine bases [93°–94°] are dissolved in petroleum-spirit, and the solutions mixed, an inactive nitrolamine [154°] is at once precipitated. A second inactive compound [152°] is formed by mixing the β-piperidine bases (Wallach, *A.* 252, 123). Similar results have been obtained by the employment of aniline and benzylamine. The salts of the bases thus produced possess a rotatory power opposite in direction to that of the free base. No method is at present known of producing from limonene active addition-compounds with two molecules of hydracid. With excess of hydrogen chloride the same inactive dipentene dihydrochloride [50°] is always obtained. The corresponding dihydriodide seems to crystallise in two forms differing slightly in melting-point (Wallach, *A.* 239, 13).

6. **Terpinene.** (180° about). This compound is formed, together with dipentene, by the action of acids upon pinene and terpin, &c. It is said to occur in oil of cardamoms (Ev. Weber, *A.* 238, 98). Terpinene has not been obtained in an absolutely pure state, but is characterised by forming a nitrosonitrite $C_{10}H_{16}N_2O_3$ [155°] (Wallach, *A.* 239, 33). The tetrabromide is fluid, and it yields no crystallisable hydrochloride. The nitrosonitrite by the action of bases yields nitrolamines $C_{10}H_{15}{<}\begin{smallmatrix}NOH\\NH_2\end{smallmatrix}$ [116°–118°], $C_{10}H_{15}{<}\begin{smallmatrix}NOH\\NHC_6H_5\end{smallmatrix}$ [130°–131°], &c. (*A.* 241, 315).

7. **Terpinolene.** (185° about). This hydrocarbon is formed along with dipentene and terpinene by the action of acids upon pinene, &c.

With hydrogen chloride and hydrogen bromide terpinolene unites to form the dipentene dihydrochloride [50°] and dihydrobromide [64°]. It forms an optically inactive tetrabromide which crystallises in monoclinic tables [116°] but is gradually converted at ordinary temperatures into a porcelain-like mass.

8. **Fenchene.** A liquid isomeride of camphor (190°–193°), obtained from oil of fennel, is treated with alcohol and sodium, by which it is reduced to the alcohol $C_{10}H_{17}OH$, a colourless crystalline compound. By treating this with phosphoric chloride the chloride $C_{10}H_{17}Cl$ is formed, and from this, by heating with aniline, fenchene $C_{10}H_{16}$ (158°–160°) may be obtained. Fenchene is optically inactive. It differs from other terpenes in resisting the action of nitric acid unless heated (Wallach, *A.* 263, 149).

Isoterpenes.

Camphenes $C_{10}H_{16}$. Pinene monohydrochloride [125°] was formerly described under the name 'artificial camphor,' from its resemblance to camphor in appearance and to a certain extent in odour. This compound is remarkably stable, but may be decomposed by heating with sodium stearate or benzoate, with potassium acetate, with alcoholic potash, or, better, with a mixture of sodium acetate and alcoholic soda (Brühl, *B.* 25, 147). The resulting hydrocarbon is a camphene [51°–52°] (160°), dextro- or lævo-rotatory or inactive according to the nature of the hydrochloride used and the reagent employed, though the exact conditions which determine the production of one or other are scarcely known (Riban, *A. Ch.* [5] 6, 353).

Camphene is also formed from bornyl chloride by the action of alcoholic potash (Riban), by the action of water and magnesia (Kachler, *A.* 197, 86), or by heating with aniline to the boiling-point of the latter (Wallach, *A.* 230, 234); it is also formed from camphor chloride and from pinene hydrochloride by the action of sodium (Montgolfier, *C. R.* 89, 102). In the last case it is accompanied by a liquid hydrocarbon (170°), $C_{10}H_{20}$, which behaves like a paraffin, and is probably identical with a liquid obtained by the action of hydrogen iodide on turpentine (Berthelot), also by the action of iodine (Armstrong a. Gaskell, *B.* 12, 1756) and by the action of sulphuric acid on turpentine (Armstrong, *B.* 12, 1759).

Camphene is also formed by the action of strong sulphuric acid on turpentine, and constitutes the characteristic ingredient in the liquid formerly known as 'terebene' (Armstrong a. Tilden, *C. J.* 1879, 733).

Camphene closely resembles camphor in appearance and even somewhat in odour. It is soluble in alcohol, ether, and benzene, and crystallises in leaflets from a concentrated solution. It is incapable of combining with bromine, but it forms a compound [157°] with hydrogen chloride, which is distinguished from pinene hydrochloride by its instability, being rapidly decomposed by water with reproduction of camphene (Riban, *C. R.* 80, 1330). It is also dissociated into camphene and hydrogen chloride when volatilised (Ehrhardt, *C. N.* 54, 239). Camphene hydrochloride is said to be identical with bornyl chloride (Kachler a. Spitzer, *A.* 200, 340; *v.* also Brühl, *B.* 25, 160). Camphene does not combine with nitrosyl chloride. In contact with bromine it is slowly attacked, forming an oily monobromo- derivative (230°–240°).

Oxidised by chromic liquor, camphene yields camphor, dextro-, lævorotatory or inactive according to the character of the camphene.

By the action of phosphorus pentachloride on camphene, and subsequent treatment of the mass with an alkaline solution, salts of two phosphonic acids are formed (Marsh a. Gardner, *C. J.* 65, 35).

When camphene is heated to about 300° it is converted into liquid products which seem to include dipentene, but have not been sufficiently investigated.

Homologues of camphene.

Ethyl-camphene obtained by the conjoint action of sodium and ethyl iodide upon camphor monochloride $C_{10}H_{15}Cl$, is a colourless mobile liquid having a smell like turpentine (197·9° – 199·9°, bar. 742·1 mm.). **Isobutyl-camphene** is also a liquid (228°–229°, bar. 750·4 mm.) (Spitzer, *B.* 11, 1817).

Sesquiterpenes $C_{15}H_{24}$.

Oils of clove, calamus, cascarilla, patchouli, and cubebs contain a hydrocarbon of this composition (Gladstone, *C. J.* 1872), as also do the oils of galbanum, and savin and 'huile de cade,' a kind of tar made by distillation of the wood of *Juniperus oxycedrus* (Wallach, *A.* 238, 81). The hydrocarbon obtained from cade or cubebs (274°–275°) (S.G. $\frac{15}{15}$ = ·921) forms the following crystalline compounds: $C_{15}H_{24}2HCl$ [117°–118°], $C_{15}H_{24}2HBr$ [124°–125°], $C_{15}H_{24}2HI$ [105°–106°]. The hydrocarbon, especially when partially resinified by exposure to the air, gives the following characteristic colour reaction: dissolved in chloroform or glacial acetic acid and then shaken up with a few drops of strong sulphuric acid, the liquid assumes an intense green and then blue colour, which, when heated, passes into red (Wallach). An attempt to prepare from isoprene a polymeride of the composition $C_{15}H_{24}$ proved unsuccessful (Wallach).

Conimene $C_{15}H_{24}$, a liquid (264°) having a pleasant odour, is obtained from the incense resin (*Icica heptaphylla*) of British Guiana (Stenhouse a. Groves, *C. J.* 1871, i. 175).

Polyterpenes $C_{20}H_{32}$, *&c.*

This group includes (1) the constituents of certain natural essential oils; (2) products of artificial polymerisation of terpenes; and (3) caoutchouc and guttapercha.

1. Oleo-resin or so-called 'balsam' of copaiba (*Copaifera Langsdorffii* and other species) is a mixture of a resin with an oil (250°–260°). The latter unites with water and absorbs hydrogen chloride, with production of a deep violet colour but no crystalline hydrochloride. A similar hydrocarbon is obtained from Gurjun balsam or 'wood oil,' the product of various species of *Dipterocarpus* growing in the East, and from other essential oils.

2. When turpentine oil and other terpenes are heated for some time to about 300°, or treated with concentrated sulphuric or phosphoric acid or other agents, a large part of the hydrocarbon undergoes polymerisation. The name 'colophene' was given by Deville to the less volatile portions of the product obtained in this manner from French turpentine, apparently under the impression that it was closely related to the oil obtained by distillation of resin. Resin-oil, however, contains oxygen, and exhibits quite different characters.

Colophene is a yellowish viscid fluid, usually fluorescent, which begins to boil at about 300°, but the distillation even under reduced pressure is attended by decomposition. The boiling-point continually rises, and even at a temperature approaching dull redness a viscid residue is left which on cooling becomes nearly solid (Armstrong a. Tilden, *C. J.* Nov. 1879). The portions which distil at 300° and upwards appear to consist of saturated compounds, for they absorb mere traces of hydrogen chloride. By the action of antimony trichloride upon turpentine a solid, $C_{40}H_{64}$, is formed. This combines with hydrogen chloride to form two compounds $C_{40}H_{64}HCl$, and $C_{40}H_{64}2HCl$ (Riban, *C. R.* 1874, 389).

3. Caoutchouc *v.* vol. i. p. 677. For further information concerning the products of its decomposition by heat *v.* Pentinenes (vol. iii. p. 807) and Dipentene (*supra*).

Guttapercha, *v.* vol. ii. p. 658.

Caoutchouc is formed from isoprene by polymerisation, which sometimes occurs spontaneously under circumstances not fully understood (Tilden, *C. N.*, May 1892).

Oxidised compounds connected with terpenes.

A considerable number of oxidised compounds are known which are evidently closely connected with the terpenes, and in many cases directly derivable from them. Some of these, as, for example, borneol and camphor, occur as natural products in essential oils; others, such as terpin, are the products of the addition of water to a terpene, or, like camphor and some of its isomerides, may be formed from terpenes by oxidation. These compounds are enumerated in the following table, together with the hydrocarbons with which they are presumably immediately connected.

Hydrocarbons	Alcohols	Glycols	Ketones (?)
Cymene $C_{10}H_{14}$ (ii. 361)	Carveol $C_{10}H_{15}OH$ (i. 711)	—	Carvol $C_{10}H_{14}O$ (i. 711)

Dipentene $C_{10}H_{16}$ (*v. supra*)	Terpineol $C_{10}H_{17}OH$ (*v. infra*)	Terpin $C_{10}H_{18}(OH)_2$ (*v. infra*)	—
—	Cineol $C_{10}H_{17}OH$ (ii. 187). Syn. Eucalyptol, cajeputol	—	
Fenchene $C_{10}H_{16}$ (*v. supra*)	Fencheol $C_{10}H_{17}OH$ (*v. infra*)	—	Fenchone $C_{10}H_{16}O$ (*v. infra*)
Camphene $C_{10}H_{16}$ (*v. supra*)	Borneol $C_{10}H_{17}OH$ (i. 542)	Camphene glycol $C_{10}H_{16}(OH)_2$ (*v. infra*)	Camphor $C_{10}H_{16}O$ (i. 669)
—	Geraniol $C_{10}H_{17}OH$ (ii. 609)	—	Pulegone $C_{10}H_{16}O$ (*v. infra*)
—	Linalool $C_{10}H_{17}OH$ (iii. 146)	—	Puleone $C_{10}H_{16}O$ (*v. infra*)
—	—	—	Tanacetone or Thujone $C_{10}H_{16}O$ (*v. infra*)
Menthene $C_{10}H_{18}$ (iii. 202)	Menthol $C_{10}H_{19}OH$ iii. 203)	—	Menthone $C_{10}H_{18}O$ (iii. 204)
Dihydrocamphene $C_{10}H_{18}$ (*v.* Decinene, ii. 367)	—	—	—
Tetrahydrocamphene $C_{10}H_{20}$ (*v.* Decylene, ii. 369, *et infra*)	—	—	—

Cymene $C_{10}H_{14}$ (176°); ii. 361.

Dipentene $C_{10}H_{16}$ (176°); *v. supra.*

Fenchene $C_{10}H_{16}$ (160°); *v. supra.*

Camphene $C_{10}H_{16}$ (160°); *v. supra.*

Menthene $C_{10}H_{18}$ (167°); iii. 202.

Dihydrocamphene $C_{10}H_{18}$ *v.* DECINENE, ii. 367. The liquid produced, together with the solid monohydrochloride, by passing hydrogen chloride into pinene, yields when treated with sodium a mixture from which a liquid hydrocarbon $C_{10}H_{18}$ (148°-149°), having a smell of oranges, may be separated by fractionation, &c. (Bouveault, *C. R.* 116, 1067).

Tetrahydrocamphene $C_{10}H_{20}$ (DECYLENE, ii. 367). A liquid obtained by the action of hydrogen iodide and phosphorus upon oil of turpentine (Berthelot) and another (160°) by action of phosphonium iodide on turpentine (Baeyer) have this composition. The same formula is ascribed by Armstrong (*B.* 12, 1758) to a liquid (160°-170°) obtained by the action of iodine upon oil of turpentine and upon camphor, also by the action of sulphuric acid upon turpentine. All these products are insoluble in strong sulphuric acid, and resemble the paraffins in chemical characters.

Carveol $C_{10}H_{15}.OH$ (219°); i. 711.

Terpineol $C_{10}H_{17}.OH$. [35°]. (215°-218°). Wiggers, *A.* 33, 358; 57, 247; List, *A.* 67, 362; Tilden, *C. J.* 33, 247, and 35, 286; Wallach, *B.* 18, 618, Ref.; Kannonikoff a. Flawitzky, *J. pr.* [2] 32, 497; Bouchardat a. Voiry, *C. R.* 104, 996. Dextro- and lævo-terpineol are obtained by the action of alcoholic sulphuric acid upon *d*- and *l*-pinene respectively, or inactive by distilling terpin with very dilute sulphuric or hydrochloric acid. Terpineol as thus obtained is a viscous liquid, having an odour of white lilac. By fractional distillation under reduced pressure a portion is obtained (130°-135° at 40 m.m.), which may be crystallised by cooling to −50°, or by the introduction of a crystal of the same. These crystals melt at 30°-32°, and boil undecomposed at 218° (Bouchardat a. Voiry, *C. R.* 104, 996). Terpineol treated with sodium evolves hydrogen, but in consequence of its viscosity the action soon ceases. Contact with dilute acids converts terpineol into terpin hydrate. Hydrogen chloride and iodide react to form $C_{10}H_{18}Cl_2$ [50°] and $C_{10}H_{18}I_2$ [77°] respectively. Potassium hydrogen sulphate at 200° produces dipentene. Terpineol unites with two atoms of bromine, but excess of bromine gives rise to dipentene tetrabromide. With phenyl cyanate it yields phenyl-terpinyl-urethane $C_6H_5.NH.CO.OC_{10}H_{17}$ [110°]. These and other reactions have been repeated by Wallach, using crystallised terpineol (*A.* 275, 103). Terpineol oxidised by permanganate yields a substance $C_{10}H_{20}O_3$ [121°-122°], which probably has the constitution of an oxyterpin $C_{10}H_{17}(OH)_3$. Further oxidised by means of chromic acid this yields a crystalline compound $C_{10}H_{16}O_3$ [62°-63°] (Wallach, *A.* 275, 145).

Cineol $C_{10}H_{18}O$ (176°); ii. 187. Cineol appears to contain no hydroxyl, since it is not acted upon by metallic sodium nor by benzoyl chloride at 120°. It is also unaffected by hydroxylamine and by phenylhydrazine. Hence it appears to be neither an alcohol nor a ketone. Its relation to terpineol (*infra*) is shown by the fact that when heated with alcohol and sulphuric acid cineol is converted into terpinene and terpinolene: also that terpineol, and therefore also terpin, are partly converted into cineol by prolonged heating with phosphoric acid. Cineol oxidised by permanganate of potassium yields the potassium salts of carbonic, oxalic, and cineolic acids, with a small quantity of acetic acid. Cineol yields 45 p.c. of its weight of cineolic acid. This compound forms well-defined anhydrous crystals, which dissolve in 70 pts. of water at 15°, and in 15 pts. at 100°. They melt with decomposition at 196°-197°.

Calcium cineolate $C_{10}H_{14}CaO_5.4H_2O$ is soluble in cold water, but is completely precipitated by boiling the aqueous solution. Silver cineolate $C_{10}H_{14}Ag_2O_5.H_2O$ is soluble in both water and alcohol, but cannot be crystallised. Ethyl cineolate $C_{10}H_{14}(C_2H_5)_2O_5$, obtained by passing hydrogen chloride gas into an alcoholic solution of the acid, is a colourless liquid (155° under 11-12 mm.). By dry distillation cineolic acid yields cineolic anhydride, water, carbon dioxide, and a liquid which appears to consist of a monobasic acid (*A.* 246, 265).

Fencheol $C_{10}H_{17}.(OH)$. Fenchyl alcohol [40°-41°]. (201°). (Wallach, *A.* 263, 143; 272, 99-125). S.G. $\frac{40}{0}$ ·933 (W.). $[\alpha]_D = \pm 10{\cdot}36$ (W.). Dextro- and lævo-fenchyl alcohols are obtained by the reduction with sodium and alcohol of lævo- and dextro-fenchones respectively. Concentrated HNO_3 oxidises *l*-fenchyl alcohol to *d*-fenchone. PCl_5 gives rise to fenchyl chloride $C_{10}H_{17}Cl$ (84°-86° at 14 mm.).

Borneol $C_{10}H_{17}.OH$, i. 522.

Geraniol $C_{10}H_{17}.OH$, ii. 609.

Linalool $C_{10}H_{17}.OH$, iii. 146. Linalool is said to be convertible into the isomeric geraniol by treatment with acetic anhydride, and saponifying the resulting ester with alcoholic potash (Bouchardat, *C. R.* 116, 1253).

Menthol $C_{10}H_{19}(OH)$, iii. 203.

Terpin $C_{10}H_{18}(OH)_2$ [104°-105°]. (258°) (Wiggers, *A.* 33, 358; 57, 247; Tilden, *C. J.* 33, 247; 35, 286; Wallach, *A.* 230, 225-272). Terpin is best known in the form of its hydrate $C_{10}H_{20}O_2.H_2O$ [116-117°], a beautifully crystalline compound which on heating to 100° loses water and leaves terpin as a vitreous mass. Terpin hydrate is readily obtained by shaking turpentine oil with alcohol acidified with sulphuric or nitric acid (Flawitzky, *B.* 12, 1022; Tilden, *C. J.* 33, 247; 35, 286), and leaving the liquid to evaporate. It is an optically inactive, saturated compound, slightly soluble in boiling water, soluble in alcohol and crystallising in rhombic prisms (Rammelsberg, *P.* 63, 570; Maskelyne, *P. M.* 1879). It possesses the characters of a glycol and with hydrogen chloride yields dipentene dihydrochloride [50°]. Boiled with water containing a mere trace of mineral acid, terpin dissolves with production of terpineol and water.

Camphene glycol $C_{10}H_{16}(OH)_2$. [192°] (G. Wagner, *B.* 23, 2311).

Formation.—By the oxidation of camphene in benzene solution with a 1 p.c. solution of $KMnO_4$ (*l.c.*).

Properties.—Colourless prismatic needles (from benzene) very readily soluble in ether, alcohol, CS_2, and chloroform. Exhibits the same phenomenon as camphor when thrown on water. Sublimes when heated above 100°. Melts when warmed with water, but only dissolves in it with difficulty. Heated with acetic anhydride in a closed tube at 120°, the greater part loses water, only a small portion being converted into the acetic ester. Treatment with dilute HCl results in the loss of 1 mol. of H_2O, giving rise to a solid body, $C_{10}H_{16}O$, isomeric with camphor, which reduces ammoniacal $AgNO_3$ and reacts with hydroxylamine.

Carvol $C_{10}H_{14}O$ (228°), *v.* i. 711.

Fenchone $C_{10}H_{16}O$. [5°–6°]. (192°–193°) (Wallach, *A.* 263, 130; 272, 102). S.G. ^{19} ·9465 (W.). R_A 44·23 (W.). $[\alpha]_D$ + 71·70 and − 66·94.

Occurrence.—Dextro-fenchone is present in fennel oil, the fraction boiling between 190° and 195° consisting almost exclusively of the ketone, together with traces of anethol; derived from Thuja oil, fenchone possesses lævorotatory optical properties. *D-* and *l-*fenchone form a series of derivatives which bear to one another a relation similar to that subsisting between the two tartaric acids, and the analogy extends to the formation of racemic modifications when equal proportions of the two classes of derivatives are mixed together.

Preparation.—The fraction of fennel oil boiling between 190° and 195° is treated with concentrated HNO_3, the ketone remaining unattacked. After being freed from acid and distilled in a current of steam, the dry oil is cooled, and the fenchone crystallises out.

Reactions.—With bromine in the cold, an addition compound is formed, substitution taking place if the mixture becomes heated. P_2O_5, P_2S_5, and PCl_5 have the same action upon fenchone as upon camphor. Fenchone is dissolved by cold concentrated HCl, being thrown out of solution on warming. HNO_3 has but little action in the cold, but in a sealed tube at 120° HCN is formed (*A.* 263, 134). $KMnO_4$ oxidises fenchone to a mixture of oxalic, acetic, and dimethyl-malonic acids. *D-* and *l-*fenchone yield *d-* and *l-*fenchyl alcohols respectively on reduction with Na and alcohol (*v. Fencheol*). On heating *d-* and *l-*fenchone with ammonium formate, *l-* and *d-*fenchylamines respectively are formed. Fenchone does not react with phenyl-hydrazine or with alkaline sulphites, but both varieties form oxims [161°] with hydroxylamine.

*d-*Fenchon-oxim $C_{10}H_{16}NOH$ [161°] (240°) loses water on treatment with dilute H_2SO_4, an unsaturated dextrorotatory nitrile (218°) being formed.

*l-*Fenchon-oxim $C_{10}H_{16}NOH$ [161°] behaves in a similar manner on treatment with dilute H_2SO_4. The resulting nitrile yields with potash a lævorotatory *α*-isoxim $C_9H_{15}.CONH_2$ [114°–115°] which is readily converted by dilute H_2SO_4 into the *β*-isoxim [136°–137°].

Camphor $C_{10}H_{16}O$ (i. 669).

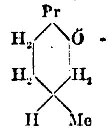
Menthone $C_{10}H_{18}O$ (206°) (iii. 204).

Pulegone $C_{10}H_{16}O$. (130°–131° under 60 mm.). (Beckmann a. Pleissner, *A.* 262, 1; Wallach, *A.* 272, 122; Semmler, *B.* 25, 3515). S.G. ^{22} ·9323 (B. a. P.); R_A 45·55 (B. a. P.); $[\alpha]_D$ 22·89 (B. a. P.). Pulegone is the chief constituent of Spanish oil of pennyroyal (*Mentha pulegium*). It is a dextrorotatory colourless liquid, having an odour of peppermint, and rapidly becoming yellow on exposure to the air.

Reactions.—With HBr it combines forming a lævorotatory ($[\alpha]_D = -33·8$) addition compound $C_{10}H_{16}O.HBr$ [40·5°]. When heated with ammonium formate, Wallach (*A.* 272, 123) failed to obtain a base isomeric with fenchylamine and thujonamine, a mixture of bases being formed. Slow oxidation with $KMnO_4$ gives rise to acetone and *β*-methyl-adipic acid [84·5°]. Rapid oxidation with the same reagent yields a *γ*-valero-lacton-*γ*-acetic acid (Semmler, *B.* 25, 3516). Pulegone combines with hydroxylamine to form pulegonoxim $C_{10}H_{19}NO_2$ [157°]. The oxim contains one molecule of H_2O more than camphoroxim. It is lævorotatory ($[\alpha]_D - 83·4$) and forms a hydrochloride [117°–118°], a benzoyl ester [137°–138°], and an acetyl ester [149°]. On heating its hydriodide pulegonamine $C_{10}H_{18}O.NH$ is formed.

Pulegone hydrobromide $C_{10}H_{16}O.HBr$ [40·5°] is lævorotatory; it forms an oxim [38°] which becomes converted on standing into normal pulegonoxim [157°]. Pulegone hydrobromide, on treatment with moist silver or lead oxide, loses HBr, pulegone being regenerated. Distillation with zinc dust gives rise to an oil which resembles menthone in every respect but the melting-point of its oxim (85° instead of 59°).

Constitution.—From the results of oxidation experiments carried on under various conditions with $KMnO_4$ Semmler (*B.* 25, 3519) attributes to pulegone the constitution:



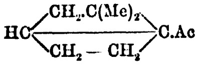
Puleone is the name given to a compound isomeric with camphor, obtained by Barbier (*B.* 25, 110*c*), from pennyroyal oil, described as boiling at 222°–223°, and possessing the following physical properties: S.G. ·9482; ^{23} ·9293; $[\alpha]_D$ + 29·15. Its oxim $C_{10}H_{16}.NOH$ is an oil (170° under 48 mm.) yielding a liquid anhydride $C_{10}H_{15}N$ on treatment with dilute H_2SO_4. Chromic acid mixture oxidises it to carbonic, acetic, and propyl-succinic [89°–91°] acids.

Tanacetone $C_{10}H_{16}O$ (195°–196°; 84·5 at 13 mm.), identical with the thujone of Wallach (*A.* 272, 109; Bruylants, *B.* 11, 450; Semmler, *B.* 25, 3343, 3519; Wallach, *l.c.*). S.G. $\frac{20}{20}$ ·9126 (S.). R_A 44·54 (S.).

Tanacetone occurs in tansy, sage, wormwood, and thuja oils. It has ketonic properties, and possesses an optical rotatory power amounting to + 38° 30′ in a 2-dcm. column.

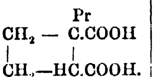
Reactions.—Sodium in alcoholic solution reduces it to tanacetyl alcohol (92·5° at 13 mm.). With alkaline hypobromite it yields bromoform and tanacetogen-dicarboxylic acid (113·5° at 15 mm.). Oxidised with $KMnO_4$ it yields tanacetocarboxylic acid, which exists in two modifications, the *α* and *β* thujaketonic acids of Wallach (*l.c.*), [75°–76°] and [78°–79°] respectively. Heated with ammonium formate, it gives tanacetylamine (198°–199°), the same body being formed when tanacetoxim (see below) is reduced with sodium and alcohol. The hydrochloride of this base on dry distillation yields tanacetene (172°–175°), a hydrocarbon of the formula $C_{10}H_{16}$, identical with Wallach's thujene. Tanacetone reacts with hydroxylamine to form tanacetoxim $C_{10}H_{16}.NOH$ [51·5°] (135°–136° at 22 mm.), which yields tanacetylamine on reduction, while treatment with dilute alcoholic H_2SO_4 converts it into a cymidine (Pr:NH_2:Me:1:3:4), which gives carvacrol with nitrous acid. Tanacetophorone $C_8H_{12}O$ (89°–90° at 13 mm.). R_A 37·6. When tanacetogen-dicarboxylic acid (produced by the action of NaBrO upon tanaceto-carboxylic acid) is heated with soda-lime, tanacetophorone is formed. It has ketonic properties, and combines with hydroxylamine.

Constitution.—Semmler (*B.* 25, 3519) suggests for tanacetone and tanacetogen-dicarboxylic acid the formulæ



Tanacetone.

and

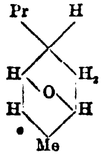


Tanacetogen-dicarboxylic acid.

Sobrerone $C_{10}H_{16}O$. *Pinol.* (183°–184°) (Wallach, *A.* 253, 254; Armstrong, *C. J. Proc.* 1890, 100). S.G. ^{20} ·953 (W.); μ_D 1·469 (W.). Sobrerone is obtained from the mother-liquors accumulated in the preparation of pinene nitrosochloride; also by boiling sobrerol with dilute H_2SO_4 (Armstrong, *l.c.*).

Reactions.—It combines readily with Br to form a dibromide [94°], from which, on treatment with alcoholic potash, sobrerone is regenerated. Sobrerone and its dibromide yield terebic acid [175°–176°] on oxidation with $KMnO_4$. HNO_3 produces the same result. It forms a nitroso-chloride [103°] which, by the action of bases, is readily converted into nitrolamines, *e.g.* sobrerone-nitrol-piperidine [154°] and sobrerone-nitrol-benzyl-amine [133°–134°]. The dibromide $C_{10}H_{16}O.Br_2$ [91°] (143°–144° at 11 mm.) yields on treatment with alcoholic potash, in addition to sobrerone, its glycol-ether $C_{10}H_{16}O(OC_2H_5)_2$ [52°–53°]. Sobrerone-glycol-diacetate is easily obtained by heating the dibromide to 150° with lead acetate in glacial acetic acid solution. When heated at 100° for three hours with formic acid, sobrerone dibromide is converted into pinene.

Constitution.—Its behaviour towards bromine and nitrosyl chloride and its molecular refraction indicate the existence of one ethylene linking, while its indifference towards acid chlorides, hydroxylamine, phenylhydrazine and H_2S render it probable that the O- atom is united to two different C- atoms. From these facts, and from its behaviour on oxidation, Wallach (*A.* 253, 259) assumes the constitution



Sobrerol $C_{10}H_{18}O_2$. [150°] (Sobrero, *C. R.* 33, 66; Armstrong, *C. J. Proc.* 1890, 100; *C. J.* 59, 315). Sobrerol is obtained by oxidising French and American turpentines in sunlight. It occurs in two optically active forms, both melting at 150°, and on allowing a mixed solution to crystallise inactive sobrerol [131°] separates out. When boiled with dilute H_2SO_4 it loses 1 mol. of H_2O, sobrerone—identical with Wallach's pinol—being formed.

Eucalyptol $C_{10}H_{18}O$ (176°) (Jahns, *B.* 17, 2941; Bouchardat a. Voiry, *C. R.* 106, 663). Identical with cineol, spicol, cajeputol, and terpan (B. a. V.).

Myristicol $C_{10}H_{16}O$ (224°) (Wright, *B.* 6, 1320; Gladstone, *C. J.* 23, 147; 25, 1; Brühl, *B.* 21, 471). S.G. ^{22} ·9446 (G.). R_A 46·42 (G.). Myristicol is a dextrorotatory alcohol, obtained from the ethereal oil of nutmeg, *Myristica aromatica.* It yields a chloride with PCl_5, and is converted into cymene by the action of $ZnCl_2$.

Absinthol $C_{10}H_{16}O$ (217°) (Beilstein a. Kupffer, *B.* 6, 1183; Wright, *l.c.* 1320; Gladstone, *C. J.* 45, 241; Brühl, *B.* 21, 471). S.G. $\frac{23}{23}$ ·9128 (G.). R_A 44·62 (G.). Absinthol is obtained from oil of wormwood, and is dextrorotatory. It is converted by $ZnCl_2$ and P_2S_5 into cymene. In what form the oxygen exists is at present unknown.

Constitution of the terpenes.

I. Pinene. The following facts must be taken into consideration:

1. Dry pinene combines with one molecule of hydrogen chloride to form a saturated compound, from which hydrogen chloride is withdrawn with difficulty, the resulting hydrocarbon being a solid camphene. Moist pinene combines with 2HCl, yielding dipentene-dihydrochloride. This also is saturated. The formation of both these compounds is undoubtedly attended by isomeric change, inasmuch as pinene cannot be recovered from either of them; but on removal of the elements of hydrogen chloride a new hydrocarbon results.

2. Pinene seems to combine with two atoms or with four atoms of bromine, according to the method of operating. By adding bromine to a cooled solution of pinene in carbon tetrachloride, Wallach has obtained a crystalline dibromide $C_{10}H_{16}Br_2$ [170°]. The yield is, however, very small, about 7 p.c. of the hydrocarbon employed (*A.* 264, 1). By shaking up a solution of pinene in chloroform, with an excess of sodium hypobromite, acidified with hydrochloric acid, so as to liberate the bromine, and immediately afterwards determining the unabsorbed excess of bromine, Tilden obtained results which pointed to the union of the terpene with four atoms of bromine. The combination is, however, very unstable, and hydrogen bromide is soon evolved (*C. J.* 53, 882). Schtschukaroff finds that a chloroform solution of pinene takes up, *in the dark*, four atoms of bromine; but the bromide formed is unstable, and quickly gives off hydrogen bromide, thus $C_{10}H_{16}Br_4 = HBr + C_{10}H_{15}Br_3$. (*B.* 23, 432, Ref.; *J. pr.* 47, 191–6).

3. Pinene combines with NOCl to form a saturated compound which is not an oxim but a nitroso- compound, and yields up the NO.Cl by the action of aniline, with liberation of an optically inactive pinene.

4. By addition of two atoms of bromine to pinene, and subsequently heating the product

alone, or, better, with aniline (Oppenheim, *B.* 5, 629), cymene is formed.

5. In contact with slightly diluted mineral acids, or when heated above its boiling-point, pinene is gradually converted into an optically inactive mixture of dipentene with terpinene, terpinolene, and polymerised terpene ('colophene').

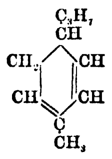
6. When heated to a temperature short of visible redness, pinene yields a considerable quantity of isoprene C_5H_8, together with a notable amount of *metâ*-xylene.

7. Pinene submitted to oxidation yields about 1 p.c. of its weight of *p*-toluic or terephthalic acid. This is perhaps due to the presence of a little cymene. It must, however, be remembered that the oxidising agent usually employed is either nitric acid or acidified chromic liquor, and hence that the pinene is first changed into dipentene or one of the other hydrocarbons referred to above (5). When nitric acid is used oxalic acid is the most abundant product, accompanied by terebic acid  $\begin{array}{l}(CH_3)_2C.CH(COOH).CH_2\\ \quad | \qquad\qquad\qquad\qquad |\\ \quad O\text{———————}CO\end{array}$ and dimethylfumaric acid  $\begin{array}{l}CH_3C.COOH\\ \quad\ \| \\ CH_3C.COOH\end{array}$ (Otto a. Beckurts, *B.* 18, 826). By treatment with chromate and sulphuric acid pinene yields much acetic acid, together with some terebic acid and terpenylic acid  $\begin{array}{l}C_3H_7.CH.CH(COOH).CH_2\\ \quad | \qquad\qquad\qquad\qquad |\\ \quad O\text{———————}CO\end{array}$

8. Natural pinene rotates the plane of polarisation to the right or to the left. It therefore must be supposed to contain an asymmetric atom of carbon.

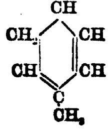
In order to epitomise these facts many formulæ have been proposed. The most important fall under two classes—namely, those in which pinene is represented as a dihydrocymene, and those in which a cross- or para-linkage is assumed.

Of the former class, the first example is the formula given many years ago by Oppenheim (*B.* 5, 98)—

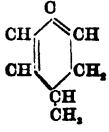


This kind of formula is now attributed with greater probability to limonene, and it must be remarked that of the possible formulæ of this type there are only four which contain an asymmetric carbon atom and *iso*-propyl.

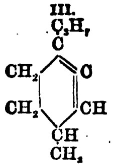
I.



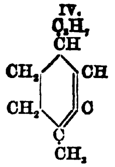
II.



III.



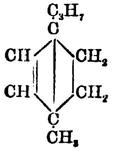
IV.



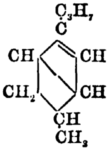
It has been shown that cymene, with which pinene is closely connected, contains *iso*- and not normal propyl (Widman, *B.* 24, 439). Hence pinene and its isomerides are believed also to be isopropyl compounds.

Formulæ containing cross- or para- linkages have been proposed as follows:—

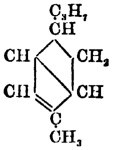
Kannonikoff (*J. pr.* 32, 517) V.



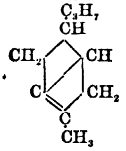
Wallach (*A.* 239, 49) Collie (*B.* 25, 1108) VI.



Wallach (*B.* 24, 1539) VII.



Wagner (*B.* 24, 2187) VIII.



II. **Limonene.**—1. Dry limonene combines with one molecule of hydrogen chloride, but unlike the hydrochloride derived from pinene the resulting compound is optically active and is not saturated, as it combines with halogens, with nitrosyl chloride, and, in the presence of moisture, with a second molecule of hydrogen chloride (Wallach, *A.* 270, 188). Limonene in the presence of water or alcohol readily yields dipentene dihydrochloride [50°], identical with the product formed from pinene. The dihydrochloride is optically inactive.

2. Limonene unites with four atoms of bromine, forming a crystalline tetrabromide.

3. Limonene unites with one molecule of nitrosyl chloride. The product, of which two (stereo?) isomerides occur, gives the reactions of an oxim.

4. Limonene readily yields abundance of cymene identical with that which is obtained from pinene (Oppenheim, *B.* 5, 628).

5. Limonene is polymerised by heat much less readily than pinene, and is not convertible into camphene.

6. Limonene vapour at a low red heat yields isoprene in the same way as pinene.

7. Limonene oxidised by nitric acid or by chromate yields oxalic, acetic, terebic or terpenylic acids according to circumstances, usually without any trace of toluic or terephthalic acid.

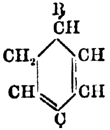
8. Limonene is dextro- or lævo-rotatory. A

mixture of equal volumes of the active hydrocarbons constitutes dipentene, which, on account of its peculiarities, quite different from those of its components, was long regarded as a distinct hydrocarbon.

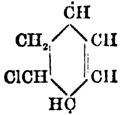
The formula which agrees best with the characters of limonene is either I. or II. given above (see *Pinene*).

In both of these there is an asymmetric carbon atom, and as the mono-hydrochloride is optically active while the dihydrochloride is inactive, these compounds will probably be represented by the following formulæ:—

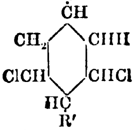
Limonene



Monohydrochloride

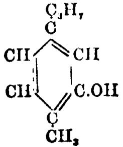


Dihydrochloride

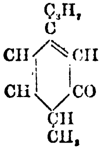


Limonene nitrosochloride deprived of the elements of hydrogen chloride yields a compound which has been identified with carvoxim. If the following formulæ be assumed for carvacrol and carvol, the interrelation of these compounds is obvious.

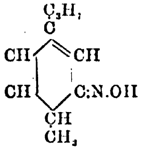
Carvacrol



Carvol

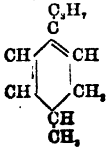


Carvoxim

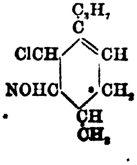


The corresponding formula for limonene should be No. II., but if that correctly represents the constitution of the hydrocarbon, the production of the nitrosochloride, or of the oxim from it, must be attended by isomeric change involving a re-distribution of the hydrogen and of the double linkages. Thus:—

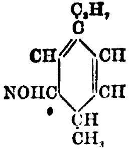
Limonene



Nitrosochloride

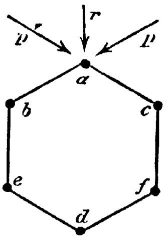


Oxim

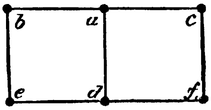


The oxim is optically active.

The very ready conversion of pinene into dipentene (=limonene) is a point of considerable importance, and it appears probable that the products formed by the action of heat and acid oxidising agents are in reality derived, not directly from pinene, but from the isomeric hydrocarbon into which it is first converted. The splitting up of pinene by heat into isoprene has been regarded (Wallach, *A.* 239, 48; Collie, *B.* 25, 1111) as supporting the formulæ already given VI. and VII., in which a para- or cross linkage is adopted. But remembering that isoprene is converted by polymerisation, not back again into pinene, but into dipentene, this evidence is of little importance. On the other hand, the difficulties involved in the assumption of a cross link in a cycloid of six carbon atoms are very considerable. In any closed ring of carbon atoms, the stability of the ring is easily accounted for upon simple mechanical principles. For if we consider six carbon atoms situated at the angles of a regular hexagon, and each attracted to its two neighbours on either side, whatever be the forces of attraction between them the resultant of those forces will have the effect of urging each carbon atom toward the centre of the figure. Thus, if the carbon atom *a* is attracted towards the carbon atom *b* with a force represented by *p*, and towards *c* with a force represented by *p'*, in the figure, the resultant of these two pressures will be *r*, which acts towards the centre; and so with each of the five other atoms.

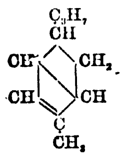


This conception is, of course, independent of any hypothesis concerning the fourth unit of valency, and the formula has no reference to the well-known 'centric' formula. The modern hypothesis according to which the carbon atom is supposed to be situated at the centre of a regular tetrahedron while the radicles with which it is united are placed at the angles of the same supplies no distinction between the force and the direction of the unit of affinity. The difference of specific volume observed between carbon compounds of the aromatic and fatty series seems to indicate that carbon atoms in the former are more closely united together, but it appears that no compounds are known in which the specific volume of carbon differs very greatly from its normal value. Hence it appears probable that the carbon atom, in uniting with other atoms, preserves a nearly constant distance from them, and in the figure above to suppose that *a* is combined with *d* as firmly as with *b* or *c* requires the assumption that a carbon atom is capable of acting through a distance twice as great in one case as in another. If this is possible, and we imagine the force of attraction between *a* and *d* to be as great as between *a* and *b* or *c*, then, unless *c* acts upon *e* and *b* acts upon *f* at the same time with the same force the figure will be changed from the hexagon to a double square.

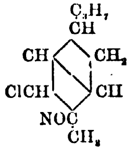


A compound of this kind would be incapable of many of the changes which are characteristic of pinene, and a second cross linkage between *c* and *e*, or between *b* and *f*, would be impossible. Hence the following formulæ, which are attributed by Wallach to nitrosopinene and pinylamine cannot be accepted even if a single diagonal is allowed in the formula of pinene.

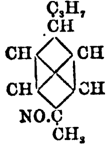
Pinene



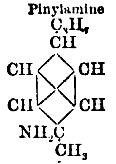
Nitrosopinene hydrochloride



Nitrosopinene



Pinylamine



Formulæ III. and IV. now remain to be considered. So far as the writer is aware, formulæ of this type have not been proposed for any of the terpenes. Nevertheless there is much to be said in favour of an expression of this kind for a compound so unstable as pinene, which appears to be incapable of withstanding the action of heat or of contact with any reagent without isomeric change. For example, the conversion of pinene into dipentene, terpinene, and terpinolene may be explained with the minimum amount of hypothesis by the following formulæ, in which the tendency towards the conversion of an unsymmetrical into a symmetrical molecule is clearly shown. The question as to the relative positions of the methyl and propyl groups is left open.

Pinene

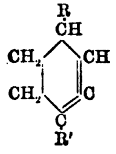
Dipentene

Terpinene or Terpinolene

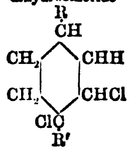
Terpinolene or Terpinene

The conversion of pinene into dipentene through the dihydrochloride is readily shown.

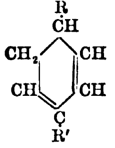
Pinene



Dipentene dihydrochloride

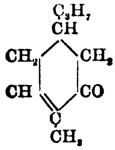


Dipentene

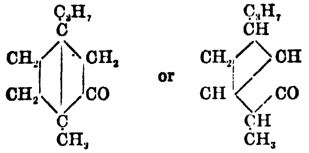


Such a formula for pinene also explains the extreme instability of its tetrabromide.

III. Camphene. Camphene behaves towards all reagents—such as bromine and nitrosyl chloride—as a saturated compound, but with hydrogen chloride it unites, forming a compound which in external appearance resembles pinene monochloride, but differs from that compound by its instability.' When camphene is oxidised by chromic acid it yields camphor, but when treated with permanganate a glycol is formed. This compound crystallises in odourless small monoclinic prisms, which sublime at temperatures above 100° (192° ca.). Its most characteristic property is seen in its reaction with dilute acids, whereby water is separated and a compound isomeric with camphor formed. This reaction appears to indicate the existence of one ethylenic bond in camphene (G. Wagner, *B.* 23, 2307). Brühl (*B.* 25, 160) also finds, as the result of his latest determinations of the molecular refraction and dispersion of camphene, that this hydrocarbon contains one ethylenic linkage. Wallach (*B.* 24, 1555) upon other grounds appears to hold the same view. Camphene is, however, so closely connected with camphor that the constitution of the latter compound when settled may serve as a guide in determining the constitution of the former. The formula for camphor given by Kekulé (*B.* 6, 931) was based upon the supposed intimacy of its relation to cymene and carvacrol.



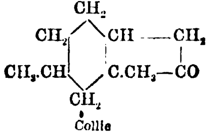
There can be no serious doubt of its character as a ketone, inasmuch as it yields an oxim, though it gives no compound with $NaHSO_3$; but the action of dehydrating agents upon camphor is very complicated, and there can be no doubt that the production of cymene is attended by isomeric change. Armstrong a. Kipping (*C. J.*, Jan. 1893) have shown that among the products of the action of strong sulphuric acid upon camphor there is a considerable quantity of acetyl-orthoxylene (C_6H_2Me.Me.Ac, Me:Me:Ac = 1:2:4). From observation of its molecular refraction Brühl (*B.* 21, 467) suggests a formula containing a para- linkage, either



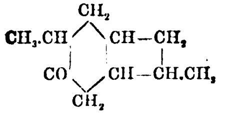
The former of these two formulæ has also been used by Wallach (*B.* 24, 1555). These expressions are equivalent to representing camphor as a derivative of tetramethylene.

A formula of a different character has been suggested by Armstrong a. Miller (*B.* 16, 2260) (*v.* vol. i. p. 670), and another of somewhat similar type by Collie (*B.* 25, 1114):

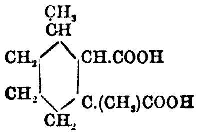
Armstrong



Collie



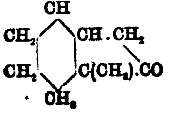
Camphor by oxidation with nitric acid yields camphoric acid in large quantity, and as the characteristic and chief product. Camphoric acid is therefore probably derived from camphor by an operation of a simple kind without constitutional disturbance. The following formula proposed by Collie (*B.* 25, 1116) has been shown to possess a very high degree of probability (Walker, *C. J.*, April 1893):



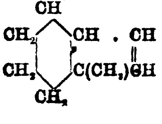
This formula sufficiently accounts for the chief facts concerning camphoric acid, viz. that it is a saturated dibasic acid, which readily yields the anhydride by heating; that it is optically active, and when treated with hydrogen iodide yields tetrahydro- and hexahydro-*m*-xylene.

From this formula are deducible the following formulæ for camphor and camphene:

Camphor



Camphene



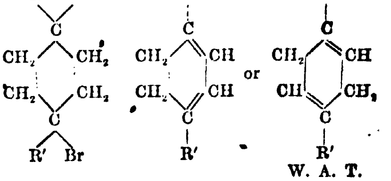
This formula for camphene explains pretty well all its relations, except its derivation from pinene, if either of the formulæ containing a para- linkage be adopted. The chief objections to such formulæ are stated above.

J. Bredt (*B.* 26, 3047) has recently proposed formulæ for camphene, camphor, and camphoric acid, which are derived from a pentamethylene ring.

Synthesis of Terpenes.

Von Baeyer in a series of papers has shown that various dihydro- derivatives of benzene and its homologues may be synthetically produced. Starting with succino-succinic ester, this compound, by treatment with dilute sulphuric acid, yields diketo-hexamethylene, and this, by reduction with sodium-amalgam, gives the corresponding glycol. This glycol possesses the characters of a sugar, and has been named chinite or quinite (*B.* 25, 1037). It occurs in two isomeric forms, which by treatment with hydrogen bromide yield two dibromohexamethylenes. Both of these by heating with quinoline yield dihydrobenzene (*B.* 25, 1840), a liquid which has nearly the same boiling-point as benzene, but combines with HBr and with Br_4. It also reduces permanganate. By a corresponding series of processes dihydro-*p*-xylene was obtained from dimethyl-succino-succinic ester (*B.* 25, 2122). Dihydro-*p*-xylene (134° circa) smells of turpentine, unites with hydrogen bromide, but forms no crystallisable nitrosite.

In order to produce a dihydrocymene it is necessary to start from the methyl-propyl compound of succino-succinic ester. This compound was obtained by heating the sodium compound of the monopropyl ether with methyl iodide (*B.* 26, 233). Methyl-isopropyl-dihydrobenzene boils at about 174°. It smells like turpentine and resinifies in the air. It decolourises permanganate and unites with bromine, forming an uncrystallisable bromide. Although closely resembling a terpene, however, it is obvious that this hydrocarbon is not identical with any natural terpene known, containing, as it does, no asymmetric carbon. It may be identical with terpinene. The relations of the paradibromohexamethylene, or of its alkyl derivatives, to the corresponding hydrocarbon is shown in the following formulæ (*B.* 25, 1840, 2122):



W. A. T.

TERPENYLIC ACID $C_8H_{12}O_4$. [72°] (Fittig); [58°] (Wallach). Formed, together with terebic acid, by oxidising oil of turpentine and other terpenes with chromic acid mixture (Hempel, *B.* 8, 357; *A.* 180, 77; Fittig a. Krafft, *A.* 208, 71). Formed also by oxidising pinol hydrate [131°] with $KMnO_4$ (Wallach, *A.* 259, 318). Monoclinic prisms (containing aq).

Reactions.—1. Yields acetic acid and CO_2 on further oxidation by *chromic acid*.—2. On *dry distillation* it yields teracrylic acid (218°), a very little oxy-heptoic lactone (212°), and other bodies (Amthor, *J. pr.* [2] 42, 388).—3. Reduced by HI and P to β-isopropyl-glutaric acid (Schryver, *C. J.* 63, 1344).

Salts.—BaA'_2. Amorphous powder, v. e. sol. water. Converted by boiling with baryta into barium diaterpenylate $Ba(C_8H_{13}O_5)_2$ aq, which separates in needles on heating the cold saturated solution and is v. sl. sol. water. On adding an acid the liberated diaterpenylic acid at once changes to its lactone, terpenylic acid.—CuA'_2 *x*aq.—AgA'. Crystalline mass. Silver diaterpenylate $AgC_8H_{13}O_5$ is ppd. by adding $AgNO_3$ to a solution of barium diaterpenylate.

Ethyl ether EtA'. [38°]. (305° i.V.). Monoclinic crystals; $a:b:c = 1{\cdot}051:1:{\cdot}381$; $\beta = 50°\ 58'$. V. sol. alcohol and ether, sl. sol. cold water. Sodium converts it into (α)- and (β)-diterpodilactone $C_{15}H_{22}O_5$.

(α)-Diterpodilactone $C_{15}H_{22}O_5$. [154°]. Formed as above (Fittig, *A.* 256, 113). Long needles (from water), m. sol. alcohol. Yields $CaC_{15}H_{24}O_7$ 6aq, $Ag_2C_{15}H_{24}O_7$, and $BaC_{15}H_{24}O_7$ 6aq crystallising in monoclinic prisms; $a:b:c = {\cdot}935:1:{\cdot}595$; $\beta = 65°\ 54'$, which, when decomposed by HCl and immediately extracted with ether yields (α)-diterpolactonic acid $C_{15}H_{24}O_8$ [160°]. This acid decomposes above 160° into water and its lactone.

(β)-Diterpodilactone $C_{15}H_{22}O_5$. [135°]. A product of the action of Na on terpenylic ether (Fittig, *A.* 256, 122). Needles, m. sol. alcohol. Converted by baryta into (β)-diterpolactonic acid [187°] and (β)-diterpoxylic acid $C_{15}H_{26}O_7$. (β)-diterpolactonic acid forms trimetric crystals; $a:b:c = {\cdot}732:1:{\cdot}259$ and is re-converted by heat into the lactone. (β)-Diterpoxylic acid forms the salts BaA″ 3½aq, CaA″, and Ag_2A''.

(α)-Diterpylic acid $C_{16}H_{22}O_7$. (α)-*Diterpodilactone carboxylic acid.* [216°]. An intermediate product of the action of Na on terpenylic ether. Needles, m. sol. alcohol. Converted by boiling HClAq or by heating above 216° into (α)-diterpodilactone.

TERPILENE *v.* TERPENES.

TERPILENOL $C_{10}H_{18}O$. [c. 32°]. (c. 130° at 50 mm.). S.G. c. ·95. H.C. (inactive) 113,318; (active) 102,923 (Louguinine, *C. R.* 107, 1165). Got by saponification of the terpilene acetates $C_{10}H_{16}HOAc$ or terpilene formates $C_{10}H_{16}CH_2O_2$ by alcoholic potash (Lafont, *A. Ch.* [6] 15, 205). Crystals, insol. water, v. sol. oil of turpentine, alcohol, and ether. Boils with decomposition at 220°. Occurs in several forms varying in their action on polarised light.

Reactions.—1. HCl forms $C_{10}H_{16}2HCl$ [48°], which is inactive even if the terpilenol were active.—2. Alcohol and HNO_3 give $C_{10}H_{22}O_3$ [104°].—3. *Phthalic anhydride* forms terpilene $C_{10}H_{16}$.—4. Ac_2O at 100° forms the acetyl derivative or terpilene acetate.

Acetyl derivative $C_{10}H_{17}OAc$ or $C_{10}H_{16}HOAc$. (220°). S.G. ^{2} ·971. V.D. 6·6. Obtained by heating terpilene with HOAc at 150°. Liquid (Bouchardat a. Lafont, *C. R.* 102, 1555).

Formyl derivative $C_{10}H_{17}O.CHO$. $[\alpha]_D = -69°\ 25'$. S.G. ^{2} ·999. Formed from oil of turpentine and cold formic acid (Lafont, *C. R.* 106, 140). By heating with water at 100° 65 p.c. of the ether is saponified.

TERPIN *v.* TERPENES.

TERPINEOL *v.* TERPENES.

TERPYLONIC ACID $C_9H_{14}O_6$. [135°]. A product of the oxidation of turpentine by chromic acid mixture (Schryver, *C. J.* 63, 1328). Needles, v. e. sol. water, m. sol. ether. Differs from camphoronic acid in electrical conductivity.

TETANINE *v.* PTOMAÏNES.

TETRADECANAPHTHENE $C_{14}H_{28}$. (241° cor.). S.G. ^{2} ·839. Occurs in petroleum from Baku (Markownikoff a. Ogloblin, *J. R.* 15, 339).

***n*-TETRADECANE** $C_{14}H_{30}$. *Diheptyl.* [4·5°]. (253°). S.G. $\frac{5}{4}$ ·775; $\frac{15}{4}$ ·768. Formed by heating myristic acid with HI and P (Krafft, *B.* 15, 1700). Got also by the action of Na on *n*-heptyl iodide (Krafft, *B.* 19, 2223; Sorabji, *C. J.* 47, 37).

Reference.—DI-BROMO-TETRADECANE.

TETRADECENOIC ACID $C_{14}H_{26}O_2$ *i.e.* $C_6H_{13}.CH{:}C(C_5H_{11}).CO_2H$. *Amylhexylacrylic acid.* Formed by the action of alcoholic potash on œnanthol (Perkin, *B.* 15, 2803; 16, 211). Liquid, boiling *in vacuo* at 275° to 280°.

TETRADECENOIC ALDEHYDE $C_{14}H_{26}O$ *i.e.* $CH_3[CH_2]_5CH{:}C(CHO)[CH_2]_4CH_3$. (278°). S.G. $\frac{15}{15}$ ·849. Formed by the action of alcoholic potash or of $ZnCl_2$ on œnanthol (Perkin, *C. J.* 43, 47). Oil, not solid at −20°. Forms crystalline $C_{14}H_{16}ONaHSO_3$. Yields hexoic and heptoic acids on oxidation.

TETRADECENYL ALCOHOL $C_{14}H_{28}O$. (282°). S.G. $\frac{15}{15}$ ·852. Formed by reducing the preceding aldehyde with sodium-amalgam (Perkin, *B.* 15, 2808). It is also a product of the action of sodium-amalgam on a solution of œnanthol in HOAc (Perkin, *C. J.* 43, 68). Oil. May be reduced to $C_{14}H_{30}O$.

Acetyl derivative $C_{14}H_{27}OAc$. (285°–290°). S.G. ^{15} ·868. Combines with Br (2 atoms).

TETRADECINENE $C_{14}H_{26}$ *i.e.* $CMe{:}C.C_{11}H_{23}$. [6·5°]. (134° at 15 mm.). S.G. $\frac{6{\cdot}5}{4}$ ·8064; $\frac{15{\cdot}2}{4}$ ·8000. Formed from tetradecylene bromide and alcoholic potash at 150° (Krafft, *B.* 17, 1372; 25, 2249).

TETRADECOIC ACID $C_{14}H_{28}O_2$ *i.e.* $C_5H_{11}.CH(C_7H_{15}).CO_2H$. (300°–310°). Got by the action of moist Ag_2O on the corresponding aldehyde (Perkin, *C. J.* 43, 74). Liquid, not solid at −10°.

Tetradecoic acid *v.* MYRISTIC ACID.

Reference.—OXYTETRADECOIC ACID.

TETRADECOIC ALDEHYDE $C_{14}H_{28}O$ *i.e.* $C_5H_{11}.CH(C_7H_{15}).CHO$. [30°]. (267°). S.G. $\frac{30}{30}$ ·827. A product of the action of Na on an ethereal solution of œnanthol (Perkin, *C. J.* 43, 71). Tables, v. sol. alcohol. Reduces ammoniacal $AgNO_3$. Yields heptoic, hexoic, and acetic acids on oxidation.

Isomeride *v.* MYRISTIC ALDEHYDE.

***n*-TETRADECYL ALCOHOL** $C_{14}H_{30}O$. [38°]. (167° at 15 mm.). S.G. $\frac{50}{4}$ ·8153. Formed by reducing myristic aldehyde (Krafft, *B.* 16, 1720).

Acetyl derivative $C_{14}H_{29}OAc$. [13°]. (176° at 15 mm.).

Tetradecyl alcohol $C_5H_{11}.CH(C_7H_{15}).CH_2OH$. (270°–275°). S.G. $\frac{15}{15}$ ·8368. Formed by reducing the corresponding aldehyde or the aldehyde $C_{14}H_{28}O$ (Perkin, *B.* 15, 2811; *C. J.* 43, 76). Liquid, solidifying at −10°.

Acetyl derivative $C_{14}H_{29}OAc$. (c. 278°). S.G. $\frac{15}{15}$ ·856. Oil, not solid at −10°.

n-**TETRADECYLENE** $C_{14}H_{28}$ *i.e.* $CH_2{:}CH.C_{12}H_{25}$. [−12°]. (127° at 15 mm.) S.G. $\frac{0}{4}$ ·7852; $\frac{15}{4}$ ·7745. Formed by distilling tetradecyl palmitate at 500 mm. (Krafft, *B.* 16, 3021). Liquid.

Bromide *v.* DI-BROMO-TETRADECANE.

TETRADECYLENE GLYCOL *v. Di-iso*-BUTYL PINACONE.

TETRADECYL-MALONIC ACID $C_{17}H_{32}O_4$ *i.e.* $C_{14}H_{29}CH(CO_2H)_2$. [118°]. Formed by boiling its nitrile with alcoholic potash (Hell a. Jordanoff, *B.* 24, 988). White powder (from HOAc), insol. water, v. sl. sol. ether, sl. sol. cold alcohol. At 150°-170° it is split up into CO_2 and palmitic acid.—Ag_2A'': white pp.

Amide $C_{14}H_{29}.CH(CO_2H)(CONH_2)$. Pearly scales. At c. 140° it yields palmitic amide.

Nitrile $C_{14}H_{29}.CH(CO_2H).CN$. [76°]. Formed by heating *p*-bromo-palmitic ether with alcoholic KCy. Silky plates (from HOAc).

n-**TETRA-ICOSANE** $C_{24}H_{50}$. [51°]. (243° at 15 mm.). S.G. $\frac{76}{4}$ ·763; $\frac{95}{4}$ ·748. Formed by the action of HI and P on $C_{17}H_{35}.CCl_2.C_6H_{13}$ made from the ketone obtained by distilling barium stearate with barium heptoate (Krafft, *B.* 15, 1718).

TETRA-ICOSOIC ACID $C_{23}H_{47}.CO_2H$. [72·5°]. Occurs in the soap got by heating carnaüba wax with aqueous NaOH (Stärcke, *A.* 223, 307). Crystalline powder, v. sol. hot alcohol.—PbA'_2. [111°]. Sol. toluene and hot HOAc.

TETRAZOLE  $N{<}\begin{smallmatrix}N=N\\CH.NH\end{smallmatrix}$ [155°]. Formed by treating amido-phenyl-tetrazole carboxylic acid with alkaline $KMnO_4$ followed by HNO_3 (Bladin, *B.* 25, 1412). Plates (from toluene). Reddens blue litmus.

TETRAZYL-HYDRAZINE $NH_2.NH.C{<}\begin{smallmatrix}N-N\\NH.N\end{smallmatrix}$ [199°]. Formed from amido-tetrazotic acid by diazotisation and reduction by $SnCl_2$ (Thiele, *A.* 273, 155). Yellowish crystalline aggregates, v. sol. hot water.—$B''2HCl$. [176°]. Aceto-acetic ether forms  $\begin{smallmatrix}CH\ .CO\\CMe.NH\end{smallmatrix}{>}N.C{<}\begin{smallmatrix}N-N\\NH.N\end{smallmatrix}$ [215°] crystallising in needles.

TETRIC ACID $C_{10}H_{12}O_6$ *i.e.*  $CH_2{:}C(OH).CMe{<}\begin{smallmatrix}O\ .CO\\CO.O\end{smallmatrix}{>}CMe.C(OH){:}CH_2$ (Nef, *A.* 266, 92) or $CH_3.CO.C(CO_2H){:}CH_2$. *Acetyl-acrylic acid.* [189°]. (262°). S. 1·5 at 14°. *Electrical conductivity*: Walden, *B.* 24, 2027. Got by heating $CH_3.CO.CMeBr.CO_2Et$ at 100°, but not by heating the isomeric acid $CH_2Br.CO.CHMe.CO_2Et$ (Nef; *cf.* Pawloff, *B.* 16, 486). Formed by successive action of bromine and alcoholic potash on methyl-acetoacetic ether (Demarçay, *C. R.* 87, 351; 88, 126). Triclinic prisms (from water), v. sol. hot water, alcohol, and ether. Gives a violet-red colour with $FeCl_3$. PCl_5 gives rise to several compounds boiling between 169° and 185° which take up chlorine forming $C_5H_5Cl_5O$ (Pawloff, *Bl.* [2] 45, 181; *C. R.* 97, 99). Demarçay obtained oily $C_4H_4Cl_2O$ (?) which united with Cl and Br forming $C_4H_4Cl_4O$ [48°] and $C_4H_4Cl_2Br_2O$ [67°]. Resinified by dilute HClAq at 150°. Potash-fusion gives formic and propionic acids. Distillation with lime forms methyl ethyl ketone. Sodium-amalgam has no action.

Salts.—$(NH_4)_2A''$. Crystals, v. sol. water.—Na_2A'' 6aq.—K_2A''.—BaA'' 3aq. Needles, v.e. sol. water.—BaA'' 2aq.—$Ba_2(OH)_2A''$. Sl. sol. water.—CaA'' 2aq.—MgA'' 10aq.—ZnA'' aq.—CuA''.—Ag_2A''. Needles, sl. sol. water.

Ethyl ether  $\begin{smallmatrix}CMe{:}C(OEt)\\CO-CH_2\end{smallmatrix}{>}O$ (?). [30°]. (180° at 70 mm.) (Moscheles, *B.* 21, 2607).

Amide $C_5H_7NO_2$. [212°]. Got by heating the acid with alcoholic NH_3.

TETROLE CYANURAMIDE *v. Nitrile of* PYRROLE CARBOXYLIC ACID.

TETROLIC ACID $C_4H_4O_2$ *i.e.* $CH_3.C{:}C.CO_2H$. *Butyrolic acid.* Mol. w. 84. [77°]. (203°). Formed by boiling β-chloro-crotonic acid or β-chloro-iso-crotonic acid with dilute potash (Geuther, *Z.* 1871, 215; Friedrich, *A.* 219, 343; Kahlbaum, *B.* 12, 2338). Formed also by the action of Na and CO_2 on allylene chloride (Pinner, *B.* 14, 1081).

Preparation.—From acetoacetic ether and PCl_5, the product being freed from $POCl_3$ by heating to 115°, mixed with water, and freed from chloro-crotonic acid by distillation with steam. The residue is treated with alcoholic potash (Fittig a. Clutterbuck, *A.* 268, 96; *cf.* Friedrich, *A.* 219, 322).

Properties.—Plates (from ligroïn). May be sublimed. V. e. sol. water, alcohol, and ether. Not reduced by sodium-amalgam to crotonic acid (F. a. C.; *cf.* Aronstein, *B.* 22, 1181). Slightly volatile with steam.

Reactions.—1. Br forms di-bromo-crotonic acid [120°], which is reduced by sodium-amalgam to tetrolic acid. *Bromine* also yields $C_4H_4Br_2O_2$. [97°] (Pinner).—2. HBr forms bromo-crotonic acid [91°].—3. Heated with conc. KOHAq it forms acetone.—4. Fuming HClAq at 15° in a few weeks converts it into β-chloro-crotonic acid [94·5°].—5. Boiling with Na and MeOH yields butyric acid (A.).—6. *Chlorine* forms $C_4H_4Cl_4O_2$. 7. On heating with *iodine* in $CHCl_3$ in sealed tubes it yields di-iodo-crotonic acid (*B.* 26, 843).—8. Split up at 211° into CO_2 and allylene.—9. $KMnO_4$ forms acetic acid.

Salts.—NaA'. Crystalline.—KA' (dried at 100°). Prisms (from alcohol).—NH_4A'.—LiA' aq.—MgA'_2 3aq.—BaA'_2 3aq.—CaA'_2 3aq. Small needles.—ZnA'_2 2aq (Lagermark, *J. R.* 12, 290).—ZnA'_2 2aq (Fittig). Groups of prisms.—CdA'_2 4aq.—PbA'_2 aq. S. 1·5 in 92 p.c. alcohol at 20°.

Chloride C_4H_3OCl. Fuming liquid, carbonised by heat. Quickly decomposed by water (Lagermark, *Bl.* [2] 35, 171).

DI-TETROLUREA *v.* CARBONYL-PYRROL.

TETROLE-URETHANE *v. Ethyl ethyl* of PYRROLE CARBOXYLIC ACID.

TEUCRIN $C_{21}H_{24}O_{11}$ or $C_{21}H_{26}O_{11}$. [230°]. A glucoside occurring in *Teucrium fructicans*, a plant used in Sicily as febrifuge. Extracted by alcohol (Oglialoro, *G.* 9, 440; 13, 498). Slender yellow prisms. Boiling dilute nitric acid forms anisic, tartaric, and oxalic acids. Boiling dilute H_2SO_4 yields glucose and a yellow insoluble residue.

TEWFIKOSE. $[a]_D = 53·1°$. A sugar occurring in the milk of the Egyptian buffalo (*Bos* *bubalus*). Yields glucose on hydrolysis (Pappel a. Richmond, *C. J.* 57, 759), *v.* Sugars.

THALICTRINE. *Macrocarpine.* Occurs in *Thalictrum macrocarpum* (Hanriot a. Doassans, *Bl.* [2] 84, 83). Yellow needles, insol. water, sol. alcohol and ether. Resembles aconitine, but is less poisonous.

THALLIN *v.* Oxy-quinoline.

THALLIUM. Tl. At. w. 203·64. Mol. w. 407·28 as gas at c. 1700° (*v. infra*). Melts at 293·9° (Crookes, *C. J.* 17, 123; *cf.* Lamy, *A. Ch.* [3] 67, 385). Boils at full red heat. S.G. pressed 11·88, cast 11·81, in wire 11·91 (Crookes, *l.c.*; *cf.* Lamy, *l.c.*; Werther, *J. pr.* 91, 385; de la Rive, *C. R.* 56, 588). V.D. 232·7 at 1636°, 203·7 at 1728° (Biltz a. V. Meyer, *B.* 22, 725). S.H. ·0325 (Lamy, *l.c.*); ·0335 (17°–100°) (Regnault, *A. Ch.* [3] 67, 437). C.E. (linear) ·00003021 at 40°, ·00003135 at 50° (Fizeau, *C. R.* 68, 1125). E.C. 5·225 at 0° (Hg at 0° = 1) (Bénoit, *P. M.* [4] 45, 314; *cf.* Matthiessen, *P.* 118, 431). H.C. $[Tl^2,O]=42,240$ (*Th.* 3, 354). Latent heat of fusion c. 1040 for 203·6 g. (Heycock a. Neville, *C. J.* 65, 35). The characteristic green line of the emission spectrum has the wave-length 5347 according to Huggins (*T.* 1864. 139), 5349·6 according to Mascart (*Ann. de l'écol. norm.*, 4, 7 [1867]), and 5349·5 according to Thalén (*Détermin. des long. d'onde des raies métalliques* [Upsala, 1868]). Concerning the emission spectrum of Tl *v.* also Crookes, *Pr.* 12, 536; Nicklès, *C. R.* 58, 132; Kirchoff a. Bunsen, *A.* 155, 230, 366; Lockyer a. Roberts, *Pr.* 23, 344; Liveing a. Dewar, *Pr.* 27, 132; Hartley a. Adeney, *T.* 1884. 104; Becquerel, *C. R.* 99, 376; Wilde, *Pr.* 53, 369.

Historical.—In 1861 Crookes was preparing Se from the flue-dust of a sulphuric acid manufactory at Tinkelrode in the Harz mountains, when on distilling the impure Se he obtained a residue which showed a marked single green line in the spectrum; this line was not known to belong to the spectrum of any element, hence Crookes supposed that the impure Se contained a new element. Crookes isolated the element towards the end of 1861, and called it thallium. (from θαλλός = a green bud) (*v. C. N.* 3, 193, 303). Lamy (*A. Ch.* [3] 67, 385) noticed a new green line in the spectrum of a leaden chamber deposit about the same time as Crookes was investigating the cause of the line he had observed; in 1862 Lamy isolated a specimen of the metal which Crookes had obtained a few months before.

Occurrence. — Never uncombined. Compounds of Tl are widely distributed, but only in very small quantities. The sulphide occurs in minute quantities in many specimens of *copper pyrites* and *iron pyrites* (*v.* Crookes, *C. J.* 17, 112; Lamy, *l.c.*; Wöhler, *A.* 142, 263; Carstanjen, *J. pr.* 102, 65; Gunning, *Ar. N.* 3, 86); also in native sulphur from Lipari and Spain. Compounds of Tl are found in small quantities in many ores of As, Bi and Hg, and in preparations from these ores; also in commercial Se and Te, probably as selenide and telluride (*v.* Crookes, *l.c.*; Röppler, *Am. S.* [2] 35, 420; Herapath, *Ph.* 4, 302; Werther, *J. pr.* 89, 129). Some specimens of *lepidolite* contain small quantities of Tl compounds (*v.* Schrötter, *W. A. B.* 48 (ii.) 734; 50 (ii.) 268). A Swedish mineral called *crookesite* was found by Nordenskjold to contain from 16·3 to 18·55 p.c. Tl as selenide, along with selenides of Cu and Ag (*Bl.* [2] 7, 409). Small quantities of TlCl are found in some mineral springs and in the saline deposits from such springs (*v.* Böttger, *J. pr.* 89, 378; 90, 22; 96, 294). Traces of Tl alum have been found accompanying the double sulphates of Cs, Li, and Rb in *alumite* from the island of Volcano (Cossa, *Acad. dei Lincei* [3] 2). Small quantities of Tl compounds have been noticed in *carnallite*, *sylvine*, and *kainite* (Schramm, *A.* 219, 374). Many specimens of commercial sulphuric and hydrochloric acids contain traces of Tl compounds (*v.* Crookes, *l.c.*).

Formation.—(Crookes, *l.c.*; or *T.* 1872.)—1. By reducing Tl_2CO_3 by fusion with KCN.—2. By electrolysis of Tl_2CO_3 covered with water.—3. By electrolysis of Tl_2SO_4. — 4. By heating $Tl_2C_2O_4$ in a covered crucible.—5. By ppg. by zinc from solution of a thallous salt to which excess of NH_3Aq or NaOHAq has been added.

Preparation.—The most economical source is the flue-dust from sulphuric acid manufactories where pyrites or sulphur containing Tl compounds has been used. Many specimens of flue-dust contain no Tl compounds; in some specimens 8 p.c. Tl has been found, but only in a very few does the quantity amount to ·25 p.c. Tl (Crookes). After having been heated to dull redness, to remove any HCl, the dust is well stirred in wooden tubs with its own weight of boiling water and allowed to settle for 12 hours; the liquid is siphoned off, and the residue is again stirred with boiling water and let settle; the mixed liquids are ppd. by a considerable excess of conc. HClAq; the pp., which is crude TlCl, is well washed on a calico filter and squeezed dry. About 68 lbs. crude TlCl were thus obtained from 3 tons flue-dust (Crookes, *T.* 1872). The crude TlCl is heated with its own weight of pure conc. H_2SO_4 in a Pt dish till all HCl and most of the H_2SO_4 are removed; the $TlHSO_4$ is dissolved in c. 20 times its weight of water, the solution is nearly neutralised by $CaCO_3$, filtered, ppd. by conc. HClAq, and the TlCl so obtained is well washed, and is then boiled for a few minutes with $(NH_4)_2SAq$; the pp. of Tl_2S is filtered off, well washed with water containing H_2S, and dissolved in dilute H_2SO_4Aq; the solution is boiled to remove H_2S, ammonia is added in slight excess, and after boiling the solution is filtered and crystallised; $(NH_4)_2SO_4$, being much more soluble in water than Tl_2SO_4, remains in solution when Tl_2SO_4 crystallises out.

If small quantities of Tl are to be prepared from Tl_2SO_4, the salt is dissolved in c. 20 times its weight of water, the solution is acidulated with H_2SO_4, and electrolysed, Pt electrodes being used. If large quantities of Tl are to be prepared, Tl_2SO_4 is placed in a deep porcelain dish (holding about 4½ litres) and covered with water (c. 3 kilos Tl_2SO_4 are used at a time) and plates of pure zinc are arranged vertically around the sides of the vessel; heat is applied, and the whole of the Tl separates in a few hours as a spongy mass easily detached from the zinc by shaking. The spongy Tl is washed several times, pressed by the fingers, and then fused with KCy in a porcelain crucible to get it into a lamp (for details *v.* Crookes, *l.c.*; *v.* also Gunning, *J. pr.* 105, 343).

Crookes (*l.c.*) gives several methods for preparing pure Tl. If the starting-point is commercial Tl_2SO_4, he recommends to dissolve this salt in water, to saturate the cold solution with pure H_2S, filter, heat to boiling, and pour into boiling, dilute, pure HClAq; to filter while hot, and allow to cool; to wash the TlCl that crystallises out, by decantation, till the washings are free from H_2SO_4, and to purify by re-crystallising twice from water. The TlCl thus obtained is dried, mixed with pure Na_2CO_3, and projected, in small successive portions, into molten pure KCy in an unglazed porcelain crucible; reduction to metal is rapid. After cooling, the contents of the crucible are treated with water, the ingot of Tl is boiled for some time in water, dried, and fused over a spirit lamp (coal-gas should not be used on account of the S compounds in it) in an unglazed porcelain crucible, with free access of air and frequent stirring with a piece of unglazed porcelain, to facilitate oxidation, and the metal is poured into a porcelain mould.

Properties.—A white metal without any tinge of blue; when fused under coal-gas, liquid Tl is exactly like Hg; may be highly polished by rubbing under water; very soft, may be cut with the nail, or scratched by lead. Less tenacious than lead; does not become brittle between −18° and its m.p.; very malleable, Lamy (*A. Ch.* [3] 67, 385) says that plates $\frac{1}{15,000}$ mm. thick can be obtained; can be squeezed, but not drawn, into wire; very inelastic. Tl crystallises very easily in octahedral forms; it crackles like tin when bent; a wire of Tl seems amorphous when prepared, but under water it soon becomes crystalline. Tl quickly tarnishes in air; the film of oxide formed protects the mass of metal. The metal may be kept unchanged for years under water that has been deprived of air (*v.* Böttger, *D. P. J.* 197, 374). Tl melts easily (at 294°) without first becoming pasty; it expands considerably before melting is complete, and contracts much on cooling. Tl boils below white heat; it may be distilled in a current of H. Pieces of the metal may be welded together by pressure at the ordinary temperature. Tl is nearly as diamagnetic as bismuth. Tl gives an intense green colour to a non-luminous flame (*v. infra, Detection*). Heated in air, Tl readily burns to Tl_2O; it combines with S, Se, P, Cl, Br, I, &c., when heated with these elements; it dissolves in solutions of most acids (*v. Reactions*). The compounds of Tl are very poisonous, producing symptoms like those of lead poisoning.

The at. w. of Tl has been determined (1) by ppg. Cl as AgCl from TlCl by $AgNO_3Aq$ (Lamy, *A. Ch.* [3] 67, 385 [1862]; Hebberling, *A.* 134, 11 [1865]); (2) by ppg. I from TlI by $AgNO_3$ (Werther, *J. pr.* 92, 136 [1864]); (3) by converting Tl_2SO_4 into $BaSO_4$ (Lamy, *l.c.*; Hebberling, *l.c.*); (4) by converting Tl into $TlNO_3$ (Crookes, *T.* 1873. 277); (5) by determining S.H. of Tl (Lamy, *l.c.*; Regnault, *A. Ch.* [3] 67, 437 [1862]); (6) by determining V.D. of TlCl (Roscoe, *Pr.* 27, 426).

The mol. w. of Tl in the gaseous state is double the at. w.; in other words, the gaseous molecule is diatomic (Biltz a. Meyer, *B.* 22, 725). Ramsay (*C. J.* 55, 521) determined the depression produced in the vapour pressure of Hg by dissolving Tl in that solvent; assuming that equal volumes of dilute solutions contain equal numbers of molecules, and that the mol. w. of liquid Hg is 200, the results obtained by R. indicated the molecule of Tl dissolved in Hg to be monatomic.

Tl is distinctly a metallic element; no compounds have been isolated wherein Tl certainly forms part of the negative radicle, although there are indications of the existence of such compounds (*v.* THALLIUM DIOXIDE, p. 680); the compounds which $TlBr_3$, $TlCl_3$, and TlI_3 form with alkali halides *may* contain Tl in the negative radicles. Tl is the last element in the odd-series family of Group III.; this family comprises Al, Ga, In, and Tl. The element Tl also shows marked resemblances to the alkali metals; and in its physical properties it is more like lead than any other element. The position assigned to Tl by the periodic classification of the elements clearly indicates the relations between this element and other elements. The relations of Tl (III.–11) to Al (III.–3) should be similar to those of Hg (II.–11) to Mg (II.–3), and also similar to those between Pb (IV.–11) and Si (IV.–3). The resemblances between the compositions and properties of the oxides of Hg and Mg on the one hand, and of the oxides of Pb and Si on the other hand, are shown only in the highest oxides of these elements: there is Hg_2O but no Mg_2O, there is PbO but no SiO; HgO and MgO are basic, PbO_2 and SiO_2 are feebly acidic. Nevertheless Hg and Pb form lower oxides than HgO and PbO_2; these lower oxides, Hg_2O and PbO, are basic; Hg_2O feebly, and PbO strongly, basic. Hence it is likely that the resemblances between the oxides of Tl and Al will be shown in the highest oxides. This supposition is confirmed; Tl_2O_3 and Al_2O_3 are basic, forming salts M_2X_3, where X = the radicle of a dibasic acid; these oxides are more basic than PbO_2 and SiO_2, but less basic than HgO and MgO. As Hg and Pb form lower oxides than HgO and PbO_2, and these lower oxides are more basic than HgO and PbO_2 so Tl will likely form an oxide lower than Tl_2O_3 and this oxide will be more basic than Tl_2O_3; Tl forms the strongly basic oxide Tl_2O. Then consider the position of Tl in series 11. Consider the oxides of the members of this series: the lower oxides Hg_2O, PbO, and Bi_2O_3 are basic; the higher oxides HgO, PbO_2, and Bi_2O_5 pass from basic (HgO) to feebly acidic (PbO_2 and Bi_2O_5); therefore it is probable that the higher oxide of Tl will be less basic than HgO, but that it will not be acidic; Tl_2O_3 is a feebly basic oxide.

If the chlorides of series 11 are considered, the position of Tl in III.–11 is seen to be justified: HgO gives $HgCl_2$, which can be gasified unchanged, PbO_2 gives $PbCl_4$, which is very easily decomposed by heat, no chloride corresponding with Bi_2O_5 has been isolated; therefore Tl_2O_3 will probably give a chloride more stable towards heat than $PbCl_4$, but less stable than $HgCl_2$. $TlCl_3$ is decomposed by heating to c. 80° into TlCl and Cl. Hg_2O gives HgCl, PbO gives $PbCl_2$, and Bi_2O_3 gives $BiCl_3$, and these chlorides can all be gasified unchanged; therefore the chloride of Tl corresponding with Tl_2O will probably not be decomposed by heat; TlCl has been gasified unchanged. The relations between the elements Hg, Tl, Pb, Bi, and Mg, Al, Si may be summarised in the expressions Tl : Hg : Pb = Al : Mg : Si; and Tl : Hg = Pb : Tl = Bi : Pb. (For a further working out of the relations of Tl, *v.* Mendeléeff, *C. N.* 1880. 2; *v.* also ALKALIS, METALS OF THE, vol. i. p. 114; and EARTHS, METALS OF THE, vol. ii. p. 424.) The atom of Tl is monovalent in the gaseous molecule TlCl; the V.D. of no other compound of Tl has been determined.

Reactions and Combinations.—1. Exposed to *air* or *oxygen*, a film of Tl_2O is at once formed; when heated in air or O to somewhat below redness (c. 300°) Tl burns to Tl_2O_3, and at a higher temperature this gives Tl_2O and O (Lamy, *A. Ch.* [3] 67, 385). Moist *ozone* acts on Tl giving TlO_3H_3.—2. A compact piece of Tl does not decompose boiling *water*, decomposition begins at a red heat; but spongy Tl, as ppd. by zinc, dissolves in water forming TlOHAq.—3. Tl dissolves in solutions of most *acids*, forming thallous salts Tl_2X, where X = 2Cl, $2NO_3$, SO_4, &c.—4. Tl combines with *sulphur* and *selenion* (*v. sulphides* and *selenides*).—5. Forms alloys with many *metals* (*v. alloys*).—6. Forms compounds with *antimony* and *arsenic* (*v. antimonide* and *arsenide*).—7. A phosphide is formed by heating Tl in vapour of *phosphorus* (*v. phosphide*).—8. Combines with *chlorine*, *bromine*, and *iodine*, when heated with these elements (*v. chlorides*, *bromides*, and *iodides*).—9. Tl ppts. the *noble metals*, also *copper*, *lead*, and *mercury* from solutions of salts of these metals (Reid, *C. N.* 12, 242).

Detection and Estimation.—Tl is best detected by the intense green colour which the metal and its compounds give to the non-luminous flame of the Bunsen lamp; according to Lamy (*l.c.*) $\frac{1}{50,000}$ mgm. can be detected by the use of the spectroscope; if induction sparks are used it is said that $\frac{1}{80,000,000}$ mgm. can be detected (Cappel, *P.* 139, 628). Tl is generally estimated as TlI or Tl_2SO_4; it can also be determined volumetrically by $KMnO_4Aq$ (Willm, *Z.* 1863. 479).

Thallium, alloys of. Several alloys of Tl were prepared by Carstanjen in 1867 (*J. pr.* 102, 62) by heating the metals together. Many of the alloys are soft, and most of them readily tarnish in the air; the alloy with $\frac{1}{4}$ pt. Sb is fairly hard; and those with Bi and Pb, Bi and Cd, and Bi and Sn are hard and brittle. Alloys are described with Al, Sb, Cd, Cu, Pb, Mg (*v.* also Mellor, *C. N.* 19, 245), Hg (*v.* also Crookes, *l.c.*, and Regnauld, *C. R.* 64, 60), K, Na, and Zn; also with Bi and Cd, Bi and Pb, and Bi and Sn.

Thallium, antimonide of. A hard, grey, crystalline solid was obtained by fusing together Tl and Sb in the ratio Tl : Sb; with cold dilute H_2SO_4Aq the substance gave off SbH_3 (Carstanjen, *l.c.*).

Thallium, arsenide of. Carstanjen (*l.c.*) obtained a white, crystalline, soft substance by fusing Tl and As in the ratio Tl : As; with cold acids AsH_3 was formed.

Thallium, bromides of. The compounds TlBr and $TlBr_3$ have been isolated, and also two compounds the simplest formulæ of which are Tl_2Br_3 and $TlBr_2$. As none of the bromides has been gasified, the formulæ are not necessarily molecular; but from the analogy of TlCl, the formula TlBr probably represents the composition of the gaseous molecule of this compound.

THALLOUS BROMIDE TlBr. (*Thallium monobromide.*) Tl reacts very slowly with Br. Thallous bromide is obtained, as a white pp., by adding HBrAq or solution of a bromide to solution of a thallous salt; almost insoluble in water (Willm, *A. Ch.* [4] 5, 28). TlBr melts at 458° to a brownish-yellow liquid, which solidifies to a yellow solid (Carnelley, *C. J.* 33, 278). Thomsen gives H.F. [Tl,Br] = 41,290 (*Th.* 3, 354).

THALLIC BROMIDE $TlBr_3$. (*Thallium tribromide.*) Prepared by adding Br to TlBr suspended in water until solution is effected, and evaporating *in vacuo*. $TlBr_3$ forms a yellow crystalline solid; it is very deliquescent, becoming gradually brown and giving off Br. Very soluble in water, also in alcohol. Reduced to TlBr by SO_2Aq and other reducing agents (Willm, *l.c.*). Thomsen gives H.F. $[Tl,Br^3,Aq] = 56,450$ (*Th.* 3, 354). $TlBr_3$ combines with NH_3 to form $TlBr_3.3NH_3$; a white solid that gives off NH_3 and Br at 100°, and when more strongly heated leaves TlBr (W., *l.c.*). Also combines with NH_4Br and KBr, forming $TlBr_3.NH_4Br$ and $TlBr_3.KBr.2aq$ (W., *l.c.*; Nicklès, *C. R.* 58, 537). Rammelsberg (*P.* 146, 597) described $2TlBr_3.3KBr.3aq$.

THALLIUM DIBROMIDE $TlBr_2$ (or $TlBr.TlBr_3 = Tl_2Br_4$). Obtained in long, yellow, needles by adding TlBr to boiling $TlBr_3Aq$, in the ratio $TlBr{:}TlBr_3$, and cooling. Not decomposed at 100°; water forms $TlBr_3Aq$ and Tl_2Br_3 (*v. infra*) (W., *l.c.*).

THALLIUM SESQUIBROMIDE Tl_2Br_3, or $TlBr_3.3TlBr = Tl_4Br_6$. (*Thallo-thallic bromide.*) Orange-red hexagonal leaflets; obtained by adding HBrAq to a mixture of a thallous and a thallic salt in solution; also by adding TlBr to $TlBr_3Aq$, or by adding a little water to $TlBr_2$ ($3TlBr_2 + Aq = Tl_2Br_3 + TlBr_3Aq$) (W., *l.c.*).

Thallium, chlorides of. Tl and Cl combine to form at least four compounds: TlCl, Tl_2Cl_3, $TlCl_2$ and $TlCl_3$.

THALLOUS CHLORIDE TlCl. Mol. w. 239·01. Melts at 427° (Carnelley, *C. J.* 33, 277). Boils at 708°–719° (C. a. Williams, *C. J.* 33, 284). S.G. 7·02, after fusion (Lamy, *J.* 15, 184). V.D. at 830° to 1025° = 117·8 (Roscoe, *Pr.* 27, 426). S. ·19 at 0°, ·27 at 16°, ·28 at 16·5°, 1·6 at 63° (Hebberling, *A.* 134, 15). H.F. [Tl,Cl] = 48,580; [Tl,Cl,Aq] = 38,480 (*Th.* 3, 354).

Formation.—1. By heating Tl in Cl, keeping the Tl in excess.—2. By boiling powdered Tl in HClAq, and dissolving the film of TlCl that forms in much boiling water.—3. By adding SO_2Aq to $TlCl_3Aq$.

Preparation.—HClAq, or solution of a chloride, is added to the solution of a thallous salt; the white curdy pp. that forms is washed with cold water, dissolved in a large quantity of boiling water, and the salt that separates as the solution cools is purified by two or three recrystallisations from boiling water (Crookes, *C. J.* 17, 112).

Properties and Reactions.—A white, crystalline solid; resembling $PbCl_2$, but separating from solution in hot water in smaller and less shining crystals than $PbCl_2$. Becomes slowly violet coloured when exposed to light (Hebberling, *A.* 134, 15). Melts at 427° to a clear yellow liquid, which solidifies to a white crystalline mass. Very slightly soluble in water (*v. supra*); less soluble in water containing a little HCl; insoluble in alcohol; insoluble in ammonia; soluble in hot Na_2CO_3Aq, KOHAq, or Na_2SO_4Aq. Hot conc. *sulphuric acid* forms Tl_2SO_4 and HCl; *oxidisers* such as ClAq, *aqua regia*, $KMnO_4$Aq and HClAq, form $TlCl_3$, Tl_2Cl_3, or $TlCl_2$ (*v.* these chlorides). TlCl is reduced to Tl by *zinc and sulphuric acid*, also by adding *aluminium* to TlClAq at 90° (Cossa, *Acad. dei Lincei* [3] 2). Fusion with *sodium hydrogen sulphate* produces Tl_2SO_4 (Krause, *D. P. J.* 217, 323; Nietzki, *D. P. J.* 219, 262).

Combinations.—1. With *platinic chloride* to form $2TlCl.PtCl_4$ ($= Tl_2PtCl_6$); obtained, as a pale-yellow, crystalline powder, by mixing solutions of TlCl and $PtCl_4$; this salt is extremely insoluble in water, one part dissolving in 15,585 parts water at 15°, and in 1948 parts boiling water (Crookes, *l.c.*).—2. With *mercuric chloride*, to form $TlCl.HgCl_2$; white lustrous needles, separating from a hot solution of TlCl in $HgCl_2$Aq; all $HgCl_2$ is removed at 200° (Carstanjen, *J. pr.* 102, 141; Jörgensen, *J. pr.* [2] 6, 82).—3. With *ferric chloride* to form $3TlCl.FeCl_3$; small red prisms; obtained by adding TlCl to a hot solution of $FeCl_3$ in HClAq, and crystallising the red pp. from hot conc. HClAq; decomposed to its constituent salts by water (Wöhler, *A.* 144, 350).—4. With *chromic chloride*, to form $3TlCl.CrCl_3$ (*v.* Neumann, *A.* 244, 328).—5. According to Lepierre a. Lachaud (*C. R.* 113, 196), a conc. solution of *chromium trioxide* reacts with TlCl to form small red prisms of $CrO_3.TlCl$ [$CrO_2(OTl)Cl$], which are decomposed by water to TlCl and CrO_3Aq.

THALLIC CHLORIDE $TlCl_3$. Mol. w. not certainly known; from analogy of $AlCl_3$, $GaCl_3$, and $InCl_3$, the formula $TlCl_3$ is probably molecular.

Formation.—1. By heating TlCl with hot *aqua regia* and evaporating the solution in Cl (Willm, *A. Ch.* [4] 5, 28).—2. By dissolving freshly ppd. TlO_3H_3 in HClAq, adding HNO_3Aq, and evaporating in Cl.—3. By heating TlCl at its melting-point in Cl; it is doubtful whether the product is pure $TlCl_3$, or contains also $TlCl_2$ or Tl_2Cl_3 (Lamy, *l.c.*).

Preparation.—Cl is passed into water containing TlCl in suspension until a little of the solution ceases to give a turbidity with $PtCl_4$Aq; excess of Cl is removed by a stream of CO_2, and the solution is evaporated *in vacuo*. Crystals of $TlCl_3.H_2O$ separate, which lose water at c. 40° (Werther, *J. pr.* 91, 385).

Properties and Reactions.—The hydrate forms large colourless prisms; the dehydrated salt is a white crystalline solid. Werther (*l.c.*) also obtained a hydrate $2TlCl_3.15H_2O$ from a solution of $TlCl_3$ prepared as described. Cl begins to be given off at c. 50° to 60°; at 100° a mixture of TlCl and chlorides intermediate between TlCl and $TlCl_3$ remains (Werther, *l.c.*; Lamy, *l.c.*). $TlCl_3$ is very deliquescent; it dissolves very easily in water. Thomsen gives $[Tl,Cl^3,Aq] = 89,250$ (*Th.* 3, 354). On diluting a conc. aqueous solution considerable quantities of TlO_3H_3 and HClAq are formed. Reducing agents, such as SO_2, form TlCl.

Combinations.—1. With *ammonia* to form $TlCl_3.3NH_3$ (Willm, *A. Ch.* [4] 5, 28). A white, crystalline powder. Obtained by passing NH_3 over $TlCl_3$; by adding an alcoholic solution of NH_3 to $TlCl_3$ suspended in absolute alcohol; or by boiling TlO_3H_3 with conc. NH_4ClAq, ppg. by NH_3Aq, washing with alcoholic ammonia, then with absolute alcohol, and drying *in vacuo*. The compound is unchanged in air; water forms NH_4ClAq and Tl_2O_3; when heated NH_3, NH_4Cl, and N are given off and TlCl remains. Dissolves in HClAq, forming $TlCl_3.3NH_4Cl$.—2. With *ammonium chloride* to form $TlCl_3.3NH_4Cl$; obtained by adding NH_4Cl to a solution of TlO_3H_3 in HClAq, and evaporating *in vacuo*; large, white, quadratic crystals, probably with $2H_2O$ (Rammelsberg, *P.* 146, 597; *v.* also Nicklès, *J. Ph.* [4] 1, 25).—3. Compounds with *potassium chloride*, *cæsium chloride*, and *rubidium chloride*, $TlCl_3.3MCl.xaq$, have been obtained (*v.* Rammelsberg, *l.c.*, also *W.* 16, 709; Godeffroy, *Zeit. des allgemein. österr. Apothekerver.* 1880 No. 9; Neumann, *A.* 244, 348; Willm, *l.c.*). Neumann (*l.c.*) also describes a compound of $TlCl_3$ with *beryllium chloride*.—4. Willm (*l.c.*) describes a compound with *cupric chloride*, $2TlCl_3.CuCl_2$.—5. According to Nicklès (*C. R.* 58, 537) $TlCl_3$ forms a compound with *ether and hydrochloric acid*, to which he gives the composition $TlCl_3.Et_2O.HCl.H_2O$; it is described as a yellow fuming liquid.

THALLIUM DICHLORIDE $TlCl_2$ (or $TlCl.TlCl_3 = Tl_2Cl_4$). Lamy (*A. Ch.* [3] 67, 402) obtained a yellow, slightly hydroscopic, easily fusible solid, to which he assigned the composition $TlCl_2$, by heating Tl and TlCl in a stream of Cl so that the product always remained liquid, and allowing to cool when saturated; the substance gave off Cl, and Tl_2Cl_3 remained.

THALLIUM SESQUICHLORIDE Tl_2Cl_3; or $TlCl_3.3TlCl = Tl_4Cl_6$. (*Thallothallic chloride.*) Formed by heating dry $TlCl_3$ somewhat above 100° as long as Cl is given off; the brown liquid cools to a clear yellow, crystalline mass (Lamy, *l.c.*, p. 403). Also formed by the direct combination of Cl with molten Tl (L., *l.c.*); also by ppg. a solution containing a thallous and a thallic salt by HClAq (Willm, *l.c.*). Also obtained by dissolving Tl or TlCl in *aqua regia*, evaporating, heating till Cl ceases to be given off, and crystallising from water slightly acidified with *aqua regia* (Lamy, *l.c.*; Crookes a. Church, *C. N.* 8, 1). According to Werther (*J. pr.* 91, 390) the product of this reaction, dried at 100°, is a mixture of compounds of TlCl and $TlCl_3$, besides Tl_2Cl_3. Tl_2Cl_3 crystallises in yellow, hexagonal leaflets; unchanged in air; melting between 400° and 500° to a dark-brown liquid that solidifies with much contraction, forming a yellowish mass with S.G. 5·9 (Lamy, *l.c.*). Very slightly soluble in water; S. ·26 at 15°, ·29 at 17°, 1·9 at 100° (Crookes; Hebberling, *A.* 134, 21). The solution is said to show the reactions both of thallous and thallic compounds. Heated above 500° Cl is given off; heating in H_2S produces Tl_2S, S, and HCl (Hebberling, *l.c.*). Heating in NH_3 produces TlCl, NH_4Cl, and N (Crookes a. Church, *C. N.* 8, 1). Tl_2Cl_3 reacts with KOHAq to form TlO_3H_3, TlCl, and KCl.

OTHER THALLO-THALLIC CHLORIDES. According to Werther (*J. pr.* 91, 390), two compounds

besides Tl_2Cl_3 are obtained by evaporating TlCl in *aqua regia*, heating till Cl ceases to be given off, crystallising from water slightly acidified with *aqua regia*, and drying at 100°. To these compounds W. gives the formulæ $3TlCl.4TlCl_3 = Tl_7Cl_{15}$ and $TlCl.15TlCl_3 = Tl_{16}Cl_{46}$.

Thallium, cyanide of; *v.* vol. ii. p. 347.

Thallium, ferrocyanide of; *v.* vol. ii. p. 337.

Thallium, fluorides of. Only one fluoride of Tl has been isolated with certainty; there are indications of the existence of another.

Thallous fluoride TlF. Formula probably molecular, from analogy of TlCl. Prepared by dissolving Tl_2CO_3 in HFAq, evaporating to dryness, heating gently to remove HF, and crystallising from water; forms white, lustrous, regular octahedra (Büchner, *J. pr.* 96, 404). TlF is also said to be formed as a white sublimate by heating Tl_2O in HF gas (Kuhlmann, *C. R.* 58, 1037). Sol. in water; S. = 80 at 15°, and increases with increase of temperature; solution in water has alkaline reaction; somewhat sol. in alcohol. A *hydrate* $TlF.H_2O$ forms in monoclinic crystals by evaporating a solution of Tl_2O or Tl_2CO_3 in HFAq; it is deliquescent, and acts on glass (Kuhlmann, *l.c.*; Willm, *A. Ch.* [4] 5, 5). A *compound with fluorhydric acid*, $TlF.HF = TlHF_2$, is obtained by evaporating a solution of TlF in HFAq over H_2SO_4. Decomposed above 100° to TlF and HF. V. sol. water; S. = 100 at ordinary temperature; the solution has an acid reaction (Büchner, *l.c.*).

Thallic fluoride. By digesting TlO_3H_3 with HFAq, and also by adding HFAq to $Tl(NO_3)_3Aq$, Willm (*A. Ch.* [4] 5, 5) obtained a dark olive-green solid, becoming brown when heated, and melting to an orange-yellow liquid that became white on cooling, insoluble in water and in cold HClAq. This substance was probably thallic fluoride, or perhaps a thallo-thallic fluoride; no analyses are given.

Thallium, hydride of. Herapath (*Ph.* 4, 302) supposed that a compound of Tl and H existed; but Crookes (*C. J.* 17, 132) failed to obtain any compound either by the interaction of an acid with Tl–Zn alloy, or by heating Tl in a stream of H; the escaping H burnt with a green flame, but this was found to be due to particles of Tl carried by the stream of H.

Thallium, hydroxides of. Tl forms three compounds with O and H, namely, TlOH, TlO_2H (or TlO.OH), and TlO_3H_3.

Thallous hydroxide TlOH. (*Hydrated thallous oxide* $Tl_2O.H_2O$.) Mol. w. not known with certainty. Thomsen (*Th.* 3, 354) gives H.F. $[Tl,O,H] = 56,915$; $[Tl^2,O,H^2O] = 45,470$; $[Tl^2O,H^2O] = 3,230$.

Formation.—1. By dissolving Tl in water containing air, and evaporating.—2. By decomposing Tl_2SO_4Aq by BaOAq, filtering, and evaporating.—3. By the interaction of CaOAq and $Tl_2C_2O_4Aq$.—4. By dissolving Tl_2O in water and evaporating.

Preparation.—1. Tl ppd. by zinc is allowed to oxidise in warm, moist air, and the oxide is dissolved in boiling water; these operations are repeated till a saturated hot solution is obtained, and this solution is evaporated a little, filtered from any Tl_2CO_3 that may have separated, and allowed to crystallise (Crookes, *C. J.* 17, 132).—2. Tl_2SO_4Aq is mixed with the proper quantity of BaOAq, and the solution, filtered from $BaSO_4$, is crystallised *in vacuo*; this method is tedious, and there is much difficulty in getting rid of all BaO.—3. Thin plates of Tl are suspended over a shallow dish containing absolute alcohol, within a bell-jar from which air has been exhausted, and pure O is passed into the jar, the temperature being kept at 20°–25°; after several hours or days, C_2H_5TlO is formed as an oil in the dish; excess of alcohol is removed by heating to 100°; a little water is added, whereby TlOH is ppd.; the pp. is drained, and exposed to warm dry air till all water and alcohol are removed (Lamy, *A. Ch.* [3] 67, 385).

Properties and Reactions. — Pale-yellow, prismatic crystals. At 100° in air, or *in vacuo* over H_2SO_4 at the ordinary temperature, the crystals become black from formation of Tl_2O, without altering their crystalline form. Easily soluble in water; Thomsen (*Th.* 3, 354) gives $[TlOH,Aq] = -3,155$. The solution in water resembles KOHAq and NaOHAq in its properties; it is strongly alkaline, absorbs CO_2, ppts. heavy metals as hydroxides or oxides, feels soapy to the touch, stains the skin, neutralises acids, &c. The solution absorbs a little O on heating; when evaporated to dryness and the residue re-dissolved, a little Tl_2O_3 generally remains.

Thallic hydroxides. Two thallic hydroxides are known, TlO.OH and TlO_3H_3.

I. *Monohydrated thallic oxide*, $TlO.OH = Tl_2O_3.H_2O$. Mol. w. not known with certainty.

Formation.—1. By ppg. $TlCl_3Aq$ by alkali and drying at 100° (Lamy, *A. Ch.* [3] 67, 385).—2. By passing ozonised air through TlOHAq (Schönbein, *J. pr.* 93, 35).—3. By the action of H_2O_2Aq on Tl; according to Weltzien (*A.* 138, 129) a mixture of TlOH and TlO.OH is thus obtained.—4. Various oxidisers—*e.g.* $KMnO_4Aq$, hypochlorite solutions, &c.—convert TlOH into TlO.OH (Schönbein, *l.c.*).—5. By electrolysing a neutral or ammoniacal solution of $Tl_2(SO_4)_3$ or $Tl(NO_3)_3$; the hydroxide separates on the positive (Pt) electrode (Flemming, *J. Z.* 1869. 292).

Preparation.—$TlCl_3Aq$ is ppd. by a slight excess of KOHAq or NH_3Aq, the pp. is thoroughly washed, and dried at 100° (Lamy, *A. Ch.* [3] 67, 397; Crookes, *C. J.* 17, 132; Werther, *J. pr.* 91, 388). The air-dried pp. has the composition TlO.OH (Carnelley a. Walker, *C. J.* 53, 88).

Properties and Reactions.—A brown powder; insoluble in water and dilute alkali solutions. Heated to c. 60° begins to lose water; completely dehydrated at 115°, according to Werther (*J. pr.* 91, 385), but the residue contains some Tl_2O, as well as Tl_2O_3 (*cf.* Birnbaum, *A.* 138, 133). According to Carnelley a. Walker (*C. J.* 53, 88), dehydration is complete at 230°, and the residue is Tl_2O_3, which is stable to 360°. Dissolves in HClAq, forming $TlCl_3$; in conc. acid Cl is given off and some TlCl is produced. Dissolves in dilute H_2SO_4Aq; with conc. acid some O is given off. Dissolves in SO_2Aq, As_2O_3Aq, hot tartaric acid solution, and boiling oxalic acid solution, in each case forming a salt of Tl_2O. TlO.OH dissolves in warm conc. NH_4ClAq, giving off NH_3 and forming $TlCl_3.3NH_3$; on adding water Tl_2O_3 is ppd. as a black powder (Willm, *A. Ch.* [4] 5, 5).

II. *Trihydrated thallic oxide*, $TlO_3H_3 = Tl_2O_3.3H_2O$. Formed, as light-brown, lustrous,

microscopic, hexagonal plates, by dissolving TlO.OH in molten KOH, fusing for some time, cooling, washing with hot water, then with alcohol, and drying at 100°. Insoluble in water. Not decomposed at 340°; soluble in dilute acids (Carnegie, *C. N.* 60, 113).

Thallium, iodides of. Tl combines directly with I. At least two compounds are known: TlI and Tl_2I_3; TlI_3, and probably one, or perhaps more than one, other compound of TlI and TlI_3, seem also to exist.

Thallous iodide TlI. (*Thallium monoiodide.*) Mol. w. not known with certainty, but formula TlI is probably molecular from analogy of TlCl.

Formation. — 1. By heating together Tl and I in the ratio Tl:I.—2. By adding KIAq to solution of a thallous salt.

Preparation.—KIAq is added to a dilute solution of a thallous salt, and the yellow pp. is thoroughly washed with water and dried at 100° (Lamy, *A. Ch.* [3] 67, 405; Crookes, *C. J.* 17, 137).

Properties and Reactions.—A citron-yellow powder; melts at 439° (Carnelley, *C. J.* 33, 278), and boils at 800°-806° (C. a. Williams, *C. J.* 33, 284). S.G. 7·072 at 15·5°, after fusion 7·0975 at 14·7° (Twitchell, *Clarke's Table of Spec. Grav.* [2nd edit.] 35). Very slightly soluble in water. Determinations of solubility vary considerably; Werther (*J. pr.* 92, 130) says that 1 pt. requires 20,000 pts. water to dissolve it at 15°, and Crookes (*l.c.*) gives solubility as 1 in 4450 of water at 15° (*v.* also Hebberling, *A.* 134, 16). Crookes says TlI is somewhat more soluble, Hebberling says it is decidedly less soluble, in KIAq than in water.

When heated to c. 190° TlI becomes red, and when it melts a red liquid is formed which solidifies to a red crystalline mass having the composition TlI (Hebberling, *l.c.*, p. 18); the red variety is also obtained by crystallising from hot KOHAq (Willm, *A. Ch.* [4] 5, 28); also by crystallising from hot $KC_2H_3O_2Aq$ (Werther, *l.c.*). The red form of TlI is produced by adding KIAq to a warm conc. solution of a thallous salt (Hebberling, *l.c.*, p. 16). Red TlI crystallises in octahedral forms (W., *l.c.*). The red variety slowly changes on keeping to the yellow form.

When freshly ppd. yellow TlI is exposed to the sun's rays it becomes green and crystalline without any change in composition. The green variety of TlI is somewhat more soluble in hot water than the yellow form; it crystallises from hot water in green microscopic crystals that are very refractive. The green variety changes slowly to the yellow on keeping; the change is hastened by heating in water containing I or KI, but not by heating with pure water. When strongly heated, green TlI becomes red (*v.* Knösel, *B.* 7, 576, 893).

TlI is decomposed by warm HNO_3Aq, with separation of I. It is dissolved, without I being separated, by ClAq or *aqua regia*; Willm (*l.c.*) supposes that an iodochloride is formed. Fusion with KCN produces Tl (Werther, *l.c.*).

Thallic iodide TlI_3. This compound has not been isolated with certainty. By treating Tl with an ethereal solution of I, Nicklès (*C. R.* 58, 537) obtained a brown liquid from which brown needles gradually separated. These crystals may have been TlI_3; no analyses are given.

Double salts of TlI_3 with alkali iodides have been prepared by digesting TlI with solutions of I and alkali iodides in ether; these salts have the composition $TlI_3.MI.xH_2O$, where $M = NH_4$ and K (*v.* Nicklès, *J. Ph.* [4] 1, 25; Willm, *A. Ch.* [4] 5, 5; Rammelsberg, *P.* 146, 597). A compound $TlI_3.CuI_2.4NH_3$ is described by Jörgensen (*J. pr.* [2] 6, 82).

Thallium sesqui-iodide Tl_2I_3 or $TlI_3.3TlI = Tl_4I_6$. (*Thallothallic iodide.*) Black, lustrous needles; insoluble in water, slightly soluble cold alcohol, decomposed by boiling alcohol; decomposed slowly at ordinary temperature, quickly on heating; obtained by long-continued heating yellow TlI with excess of IAq (Knösel, *B.* 7, 576, 893).

Other thallo-thallic iodides. By evaporating a solution of TlI in HIAq, in presence of I, at 70°, small, brown, rhombic, crystals were obtained by Jörgensen (*l.c.*). The composition of the crystals is represented by J. as $6TlI.TlI_3$, or perhaps $5TlI.TlI_3$. The same compound is said to be obtained by digesting TlI with an ethereal solution of I. Heating to c. 100° drives off I, and leaves yellow TlI; boiling alcohol, and also KIAq, withdraws I, forming TlI.

Thallium, oxides of. Two oxides have been isolated, Tl_2O and Tl_2O_3; there is evidence in favour of the existence of a third oxide, probably TlO_2.

Thallous oxide Tl_2O. (*Thallium monoxide.*) Mol. w. not known with certainty. $[Tl^2,O] = 42,240$ (*Th.* 3, 354). Prepared by heating Tl in air to not above 100° (to prevent formation of Tl_2O_3); also by heating TlOH to 100° out of contact with air; also by heating Tl_2O_3 to full redness. A black powder; melting at c. 300° to a dark-yellow liquid, which acts on glass, forming a silicate of Tl. Tl_2O absorbs moisture from the air, forming TlOH; it dissolves easily in water, forming a strongly alkaline solution of TlOH (*v.* Thallous hydroxide, p. 678). Soluble in absolute alcohol, forming $C_2H_5.OTl$, a colourless, heavy oil (S.G. 3·55); this oil is decomposed by a little water with separation of TlOH (*v.* Thallous hydroxide, *Preparation*, No. 3, p. 678). (Crookes, *C. J.* 17, 128; Lamy, *A. Ch.* [3] 67, 385). Tl_2O is reduced to Tl by heating to redness in H, or in CO, or with Mg (Winkler, *B.* 23, 788).

Thallic oxide Tl_2O_3. Mol. w. not known with certainty. Prepared by ppg. a thallic salt with KOHAq or NH_3Aq, washing the pp. thoroughly, drying, and heating it to c. 260° (Crookes, *l.c.*, p. 132). Also formed by burning Tl in air to a little below redness; at a lower temperature the product is chiefly Tl_2O, and at a full red heat Tl_2O_3 is decomposed to Tl_2O and O (Lamy, *l.c.*). Tl_2O_3 is also formed by passing an electric current (from a couple of Grove cells) through neutral Tl_2SO_4Aq, using Pt electrodes; Tl deposits on the negative electrode, and Tl_2O_3 forms, as a brown cake, on the positive electrode; the H_2SO_4Aq formed should be neutralised from time to time by NH_3Aq (Crookes, *l.c.*). For other methods of formation *v.* Wöhler (*A.* 146, 263, 375), and Willm (*A. Ch.* [4] 5, 19). Tl_2O_3 is a brownish-black solid; insoluble in water Melts at c. 760° (?) (Carnelley a. O'Shea, *C. J.*

45, 409). Gives off O at a full red heat, forming Tl_2O. Dissolves in hot H_2SO_4Aq, forming Tl_2SO_4Aq and giving off O. Soluble cold HClAq, forming $TlCl_3Aq$, and some TlCl with evolution of Cl. Takes fire in dry H_2S, forming Tl_2S_3 (Carstanjen, *J. pr.* 102, 65). A mixture of Tl_2O_3 and S takes fire when struck (Böttger, *J. pr.* 90, 27). Reduced by heating in H or CO to Tl_2O, and then to Tl. Tl_2O_3 absorbs NH_3 when heated in that gas; no definite compound has been isolated. For compounds with H_2O *v.* THALLIC HYDROXIDES, p. 678).

THALLIUM DIOXIDE (?TlO_2). When a rapid stream of Cl is passed into conc. KOHAq, holding freshly ppd. TlO.OH in suspension, a violet-coloured solution is obtained; mineral acids added to this solution form thallous salts, and give off O, or Cl with HClAq. Carstanjen (*J. pr.* 101, 55) supposed the violet solution to contain a thallate of potassium. Piccini (*G.* 17, 450) obtained a violet pp. by adding $Ba(NO_3)_2Aq$ to the violet solution; analyses of this pp. were not satisfactory, but the results indicated that an oxide of Tl of the composition TlO_2 is formed by the method described. Piccini says that the same violet solution is obtained by electrolysing 30 p.c. KOHAq, using a plate of Tl as anode; also by digesting 1 pt. KOH with 4 pts. KClO, in water, and adding Tl_2SO_4.

Thallium, phosphide of. No compound of Tl and P has been isolated with certainty. According to Crookes (*C. J.* 17, 135), the black substance formed by passing P hydride into ammoniacal Tl_2SO_4Aq is a phosphide of Tl. Carstanjen (*J. pr.* 102, 80) failed to obtain a phosphide by reducing Tl_3PO_4 by C or H, or by heating the elements together. Flemming (*Bl.* [2] 10, 35) noticed that a thin, black coating formed on molten Tl when pieces of P were thrown on to it; by heating solution of a thallous salt with P in a sealed tube, he obtained a black solid, perhaps a phosphide, and also a phosphite and hydride of P (*cf.* Willm, *A. Ch.* [4] 5, 5).

Thallium, platino-cyanide of; *v.* vol. ii. p. 345.

Thallium, salts of. Two series of salts are formed by replacing the H of acids by Tl; thallous salts, Tl_2X, and thallic salts, Tl_2X_3, where $X = SO_4$, CO_3, $2NO_3$, $2IO_3$, $\frac{2}{3}PO_4$, &c. The chief thallous salts of oxyacids are *arsenates*, *carbonates*, *chlorate* and *perchlorate*, *chromate*, *dichromate* and *trichromate*, *dithionate* and *trithionate*, *hypophosphite*, *iodate* and *periodate*, *molybdates*, *nitrate*, *phosphates*, *selenite* and *selenates*, *silicates*, *sulphates* and *sulphite*, *tellurate*, *thiosulphate*. The principal thallic salts are *arsenate*, *iodate* and *periodate*, *nitrate*, *phosphates*, *sulphates* (*v.* CARBONATES, NITRATES, SULPHATES, &c.). Several double salts of both series are also known.

Thallium, salts of oxyacids of. No compounds of this kind have been isolated with certainty, but there is evidence in favour of the existence of salts of the hypothetical thallic acid, probably analogous to plumbates (*v.* THALLIUM DIOXIDE, *supra*).

Thallium, selenides of. Tl_2Se has been isolated; another selenide, perhaps Tl_2Se_3, probably exists.

THALLOUS SELENIDE Tl_2Se. Mol. w. not known. Obtained by fusing the elements together in the ratio 2Tl:Se (Willm, *A. Ch.* [4] 5, 5; Carstanjen, *J. pr.* 102, 79); also by ppg. Tl_2CO_3Aq by H_2Se (Kuhlmann, *Bl.* [2] 1, 330). A grey, lustrous, crystalline solid; melting at c. 340° (Kuhlmann, *l.c.*). Dissolves in H_2SO_4Aq and HClAq, giving off H_2Se.

THALLIC SELENIDE (?Tl_2Se_3). By fusing the elements together in the ratio 2Tl:3Se, Carstanjen (*l.c.*) obtained greyish-black prismatic crystals, resembling Sb; not acted on by dilute H_2SO_4Aq; decomposed by hot conc. H_2SO_4, with separation of Se and evolution of SO_2. The composition of this substance has not been determined.

Thallium, silicofluoride of, Tl_2SiF_6. Obtained by dissolving Tl_2CO_3 in H_2SiF_6Aq, and evaporating. Colourless, regular, octahedra (Werther, *J. pr.* 91, 385). According to Kuhlmann (*Bl.* [2] 1, 330), the crystals are $Tl_2SiF_6.H_2O$. Easily soluble in water. Volatile without decomposition, according to Kuhlmann (*l.c.*).

Thallium, sulphides of. Tl_2S and Tl_2S_3 have been isolated, and also probably more than one compound of these two sulphides.

THALLOUS SULPHIDE Tl_2S. Mol. w. not known.

Formation.—1. By fusing the elements together in the ratio 2Tl:S (Carstanjen, *J. pr.* 102, 76).—2. By ppg. an alkaline solution of a thallous salt by H_2S.—3. By ppg. slightly acidified Tl_2SO_4Aq by H_2S (Hebberling, *A.* 134, 11).—4. By heating an alkaline solution of a thallous salt with $Na_2S_2O_3$ (C., *l.c.*).

Preparation.—A cold, fairly conc., aqueous solution of Tl_2SO_4 is acidulated with a trace of H_2SO_4Aq, and saturated with H_2S, and the bluish-black pp., consisting of microscopic crystals, is washed with H_2SAq and dried over H_2SO_4 (Hebberling, *l.c.*).

Properties and Reactions.—Prepared by ppn. from slightly acidulated Tl_2SO_4Aq, Tl_2S forms very minute, blue-black, lustrous tetrahedra; prepared by heating together Tl and S it is a black, crystalline, brittle solid; prepared by ppn. from alkaline solutions it is a black amorphous solid. When the amorphous solid is dried, and strongly heated, it melts, and solidifies on cooling to a black crystalline mass. After melting, S.G. is 8·0 (Lamy, *J.* 15, 185). H.F. $[Tl^2,S] = 21,660$ (*Th.* 3, 354). Moist ppd. Tl_2S oxidises in air to Tl_2SO_4. On long continued heating Tl_2S is completely decomposed (Lamy, *l.c.*). Tl_2S is insoluble in solutions of alkalis, alkali sulphides, carbonates, and cyanides; it dissolves readily in H_2SO_4Aq and HNO_3Aq, and less readily in HClAq. By ppg. from a very dilute solution of a thallous salt, and dialysing, Winssinger (*Bl.* [2] 49, 452) obtained a reddish-brown aqueous solution of colloidal Tl_2S.

Combination.—By passing H_2S into Tl_2SO_4Aq containing As_2O_3Aq, and acidulated with dilute H_2SO_4Aq, Gunning (*Ar. N.* 3, 86) obtained a red pp. of $Tl_2S.As_2S_3$; the same compound was obtained by mixing a solution of As_2S_3 in NH_3Aq with an ammoniacal solution of a thallous salt. Heat decomposes the compound into its constituent sulphides; alkali solutions dissolve out As_2S_3, leaving Tl_2S.

THALLIC SULPHIDE Tl_2S_3. Obtained as a black, amorphous, easily fusible, solid, by melting Tl with excess of S, and removing uncombined S by heating out of contact with air (Carstanjen, *J. pr.* 102, 65). Below 12° Tl_2S_3 is hard and brittle; above 12° it is so soft that it may be drawn out like pitch. It dissolves in warm dilute H_2SO_4Aq without separation of S. Strecker (*J. pr.* [2] 2, 162) obtained a lustrous, brown-black pp. by passing H_2S into a solution of a thallic salt mixed with sodium tartrate and excess of NH_3Aq, followed by boiling; this pp. was Tl_2S_3 according to Strecker. When H_2S is passed into an aqueous solution of a thallic salt, the pp. is a mixture of Tl_2S and S. Tl_2S_3 *combines with potassium and sodium sulphides*, forming $Tl_2S_3.K_2S$ and $Tl_2S_3.Na_2S$. These compounds are obtained by fusing together 1 pt. Tl_2SO_4, 6 pts. S, and 9 pts. K_2CO_3 or Na_2CO_3, and washing the fused mass with water. The K compound is more stable than the compound of Na; when heated it melts, and then gives off S, leaving K_2S and Tl_2S; it is not changed by water or alkali solutions, but is decomposed by mineral acids (*v.* Schneider, *A.* 135, 215; *cf.* Krüss, *B.* 19, 2738). These compounds may be regarded as $KTlS_2$ and $NaTlS_2$, that is, as salts of a hypothetical thio-thallic acid.

THALLO-THALLIC SULPHIDES. By adding $(NH_4)_2SAq$ to a solution of Tl_2Cl_3, a black pp. is obtained which is more fusible than Tl_2S, and after melting solidifies to large greyish-black prisms. This pp. contains Tl and S. Similar substances are formed by heating together Tl_2S and Tl_2S_3, and by melting Tl with more S than 2Tl:S, and less than 2Tl:3S; Carstanjen (*J. pr.* 102, 65) gave the formulæ $5Tl_2S.3Tl_2S_3 = Tl_{16}S_{14}$, and $Tl_2S.Tl_2S_3 = TlS$ to compounds obtained in this way. By heating $Tl_2S_3.Na_2S$ (*v. supra*) with water, Schneider (*A.* 135, 215) obtained a compound to which he gave the formula $Tl_2S.2Tl_2S_3 = Tl_6S_7$.

Thallium, sulphocyanide of; *v.* vol. ii. p. 352.

Thallium, thiosalts of. The compounds of Tl_2S_3 with K_2S and Na_2S may be regarded as K and Na thiothallates (*v.* THALLIC SULPHIDE, *supra*).
M. M. P. M.

THALLIUM ETHIDE TlEt. Has not been obtained in the free state.

Ethylo-chloride $TlEt_2Cl$. S. 2·76 in the cold; 3·37 at 92°. S. (alcohol) ·33 at 78°. Formed from $TlCl_3$ and $ZnEt_2$ in ether (Hartwig, *A.* 176, 257). Scales (from water), explodes feebly at 190°, yielding TlCl. Reacts with silver salts forming: $TlEt_2NO_3$, S. 5·67 at 70°, exploding at 236°.—$(TlEt_2)_2SO_4$, S. 65·4 in the cold; 87·3 at 90°; exploding at 205° and converted by BaI_2 into $TlEt_2I$, S. ·1, exploding at 195°.—$(TlEt_2)_3PO_4$, S. 23·7 in the cold; 20·7 at 75°, exploding at 189°.—$TlEt_2OAc$ crystallising in needles [212°] (245°), exploding if rapidly heated.

Ethylo-hydroxide $TlEt_2OH$. S. 15·1 in the cold; 8 at 88°. Formed from $(TlEt_2)_2SO_4$ and baryta. Silky needles (from water). More sol. cold than hot water, forming an alkaline solution. Does not unite with CO_2, but forms the above salts with other acids.

THAPSIC ACID $C_{16}H_{30}O_4$. [124°]. Obtained from the root-bark of *Thapsia garganica*. The bark is extracted with ether, which leaves on evaporation an amber-coloured resin. The resin dissolves in potash with evolution of heat, and the solution, on acidification, yields a neutral resin, *n*-octoic acid and thapsic acid. The alkaline solution on standing deposits potassium thapsate (Canzoneri, *G.* 13, 514). White scales (from alcohol), nearly insol. water and benzene, sol. alcohol and ether.

Salts.—$K_2A''xaq$. Prisms.—BaA'' (dried at 120°). Crystalline pp.—Ag_2A'': amorphous.

Anhydride $C_{16}H_{28}O_3$. [71°]. Crystalline powder (from benzene).

Anilide $C_{16}H_{28}O_2(NHPh)_2$. [163°].

THEBAÏNE $C_{19}H_{21}NO_3$. [193°]. S.G. 1·3. $[\alpha]_j = -219°$ in 97 p.c. alcohol at 15°; $= -230°$ in $CHCl_3$; S. (ether) ·7 at 10°; S. (isoamyl alcohol) 1·67 in the cold; S. (benzene) 5·27 in the cold (Kubly, *J.* 1866, 823). Occurs in opium to the extent of about ·6 p.c. (Pelletier, *J. Ph.* 21, 569; Couerbe, *A. Ch.* [2] 59, 155; Kane, *A.* 19, 9; Anderson, *A.* 86, 179; Hesse, *B.* 3, 367; *A.* 153, 47; 176, 196). Prepared by treating the aqueous extract of opium with Na_2CO_3 or lime, exhausting the filtrate with ether, agitating the ether with dilute acetic acid, and pouring the acid liquid into dilute KOHAq. The pp. is collected after 24 hours, warmed with dilute alcohol and dilute HOAc is added till just acid. The alcohol is evaporated off at 50°, papaverine and narcotine removed by filtration, and thebaïne acid tartrate ppd. by adding powdered tartaric acid to the filtrate. The tartrate is re-crystallised from water (Hesse, *A. Suppl.* 8, 262). Thebaïne may also be obtained by adding NaOAc to a solution of the hydrochlorides of the opium alkaloids, allowing to stand, filtering, evaporating, again filtering, and adding sodium salicylate. After 24 hours thebaïne salicylate crystallises (Plugge, *Ar. Ph.* [3] 24, 993; 25, 343).

Properties.—Colourless leaflets (from dilute alcohol) or prisms (from conc. alcohol). Tasteless. Alkaline in reaction. Very poisonous. Begins to sublime at 135°; at 160° the sublimate contains needles, cubes, and prisms (Blyth). V. sol. alcohol and chloroform. Ppd. by alkalis and alkaline carbonates, the pp. being slightly soluble in NH_3Aq and lime-water. Conc. H_2SO_4 gives a deep-red solution. Boiling dilute H_2SO_4 converts it into thebenine and thebaïcine. Hot conc. HClAq at 90° yields MeCl and morphothebaïne (Howard, *B.* 17, 527). HIAq gives MeI (2 mols.) (Howard a. Roser, *B.* 19, 1597). Bromine-water forms $C_{19}H_{20}BrNO_3$, a flocculent pp. converted by excess of Br into $C_{19}H_{20}Br_3NO_3$, a yellow pp. Solutions of its salts give a pp. of the dichromate on adding $K_2Cr_2O_7$.

Salts.—$B'HCl$ aq. Large trimetric prisms. S. 6·3 at 10°. $[\alpha]_j = -168·32 + 2·33p$. —$B'_2H_2PtCl_6$ 2aq. Amorphous pp., quickly changing to orange prisms. Decomposed by boiling water (O. De Coninck, *Bl.* [2] 45, 131).—$B'_2H_2C_2O_4$ 6aq. S. 1·03 at 10°.—$B'H_2C_2O_4$aq. S. 2·3 at 20°.—$B'C_4H_6O_6$aq. Prisms, very soluble in hot alcohol. S. ·77 at 20°.—Meconate $B'_2C_7H_4O_7$ 6aq. White prisms (from alcohol).—$B'_4H_4FeCy_6$ (Plugge, *Ar. Ph.* [3] 25, 793).

Methylo-iodide B'MeI. Crystallises from alcohol in prisms (containing EtOH), m. sol. water.

Ethylo-chloride B'EtCl. Needles.

Ethylo-iodide B'EtI. Needles (from alcohol) (Howard, *B.* 17, 527).

Benzylo-chloride $B'C_7H_7Cl$. Crystals.

Morpho-thebaïne $C_{17}H_{17}O_3N$ [191°]. Obtained by heating thebaïne with strong aqueous HCl or

HBr, MeCl (or EtCl) being split off; the yield being 50 p.c. of the thebaïne. Yellowish crystals. Soluble in alcohol, ether, and benzene, sparingly in water. It dissolves in H_2SO_4 to a colourless solution.

Salts.—B'HCl. Small glistening crystals, sol. water, insol. alcohol.—B'HBr: fine silky needles.—$B'HNO_3$ 2aq: small white crystals, v. sol. water and alcohol.—$B'_2H_2SO_4$ 7aq: small crystals, v. sol. water, insol. alcohol. The **oxalate** is a sparingly soluble amorphous pp. The **picrate** is a yellow pp. which melts under water. Insoluble pps. are produced with potassium ferrocyanide, ammonium molybdate, $HgCl_2K_2I_2$, $K_2Cr_2O_7$, and bismuth-potassium iodide.

Acetyl derivative $C_{17}H_{18}AcO_3N$. [183°]: glistening plates (Howard, *B.* 17, 529).

Ethylo-iodide B'EtI. Crystallises from acetic acid.

Methylo-iodide B'MeI. Dimetric tables, insol. alcohol, sol. HOAc.

Benzylo-chloride $B'C_7H_7Cl$. Needles, m. sol. water, sl. sol. alcohol (Howard a. Roser, *B.* 19, 1596).

Thebenine $C_{19}H_{21}NO_3$. Formed by boiling thebaïne with HClAq (S.G. 1·04) (Hesse, *A.* 153, 69). Amorphous. Insol. benzene and ether, sl. sol. boiling alcohol. Conc. H_2SO_4 forms a blue solution. V. sol. KOHAq.—B'HCl 3aq. S. 1. Plates.—$B'_2H_2HgCl_4$ 2aq. Very long efflorescent prisms.—$B'_2H_2SO_4$ 2aq. Plates, insol. cold water. —$B'H_2C_2O_4$ aq. Prisms, sl. sol. hot water.

Thebaïcine. Formed by boiling thebaïne or thebenine with conc. HClAq (Hesse). Yellow amorphous pp., insol. ether, benzene, and water, sl. sol. hot alcohol, v. sol. KOHAq. Conc. H_2SO_4 forms a dark-blue solution. The salts are resinous.

Theïne *v.* CAFFEÏNE.

THEOBROMINE $C_7H_8N_4O_2$ *i.e.*

$\mathrm{CO}<\begin{matrix}\mathrm{NMe.C:CH.NMe}\\ \mathrm{N{=\!=}C.NH.CO}\end{matrix}$. Mol. w. 180. *Di-methyl-xanthine.* S. ·062 at 17°; ·7 at 100°. S. (alcohol) ·02 at 17°; ·2 at 78°. S. (ether) ·006 in the cold; ·17 at 35°. S. (boiling $CHCl_3$) 1. Occurs in the seeds of *Theobroma cacao* to the extent of 1·3 to 4·6 p.c. (Woskresensky, *A.* 41, 125; Glasson, *A.* 61, 335; Keller, *A.* 92, 71; Rochleder, *A.* 71, 9; 79, 124; Strecker, *A.* 118, 151). Formed by heating the lead salt of xanthine $C_5H_2PbN_4O_2$ (4 pts.) with MeI (5 pts.) for twelve hours at 130° (Fischer, *B.* 15, 454; *A.* 215, 311). Prepared by ppg. the aqueous extract of the seeds with lead acetate, filtering, removing excess of lead by H_2SO_4, adding $MgCO_3$, evaporating to dryness, and extracting with alcohol (Dragendorff, *Ar. Ph.* [3] 12, 1). Got also by freeing cacao from oil by pressure, adding slaked lime, and extracting with 80 p.c. alcohol (Schmidt a. Pressler, *A.* 217, 287).

Properties.—Minute trimetric crystals, sl. sol. hot water, alcohol, and ether. Tastes bitter. At 184° it begins to sublime; at 170° (Blyth) or 290° (S. a. P.) it yields a crystalline sublimate. Very slowly attacked by pure HNO_3 (Franchimont, *R. T. C.* 6, 223). Not attacked by boiling KOHAq. Its salts are more or less easily decomposed by water. Ammoniacal $AgNO_3$ gives a gelatinous pp. which dissolves on warming, and deposits, on boiling, crystalline $C_7H_7AgN_4O_2$ (Strecker). Theobromine is ppd. by sodium phosphotungstate (Wolfram, *C. J.* 36, 406; *Fr.* 18, 346).

Reactions.—1. Yields methyl-parabanic acid on oxidation by CrO_3.—2. $KClO_3$ and HClAq at 50° yield methyl-alloxan and methyl-urea (Fischer, *A.* 215, 304). Chlorine-water yields amalic acid.—3. Will not combine with MeI to form a methyloiodide. But in presence of dilute alcoholic KOH it reacts with MeI, forming caffeïne, even in the cold; better at 100°. But the reaction is never complete, some theobromine being decomposed.—4. Conc. HCl has no action below 200°. At 250° it decomposes it, producing formic acid, carbonic acid, ammonia, methylamine and sarcosine, $C_7H_8N_4O_2 + 6H_2O = 2CO_2 + NMeH_2 + 2NH_3 + C_3H_7NO_2 + CH_2O_2$; the NH_3 and $NMeH_2$ occur in the proportion indicated by the formula (Schmidt, *A.* 217, 298). Boiling aqueous $Ba(OH)_2$ effects in 40 hours the same decomposition.—5. HNO_3 forms CO_2, methyl-parabanic acid and methylamine, but no ammonia.

Salts.—B'HCl aq. Rosettes of needles.—B'HBr aq. Tables. — $B'_2H_2PtCl_6$ 4aq. — $B'_2H_2PtCl_6$ 5aq. — $B'HAuCl_4$. — B'_2HNO_3. — B'HOAc.—$B'_2H_2I_8$. Nearly black prisms, decomposed by alcohol (Jörgenssen, *Z.* [2] 5, 675).—$B'HAg(NO_3)_2$. Silvery needles, v. sl. sol. water.—$C_7H_7AgN_4O_2$ 1½aq.—$Ba(C_7H_7N_4O_2)_2$ (dried at 105°). Got by adding theobromine to baryta-water (Maly a. Andreasch, *M.* 4, 379). Needles (from hot water).

Bromo-theobromine $C_7H_7N_4O_2Br$. From theobromine and bromine (Fischer, *A.* 215, 305). Crystalline powder. Sl. sol. hot water. Sol. HCl, but reppd. by water. Sol. aqueous NaOH, not in NH_3. Does not give an ethoxy- derivative with alcoholic KOH (unlike bromo-caffeïne). After warming with ammonia it gives with ammoniacal $AgNO_3$ a silver salt that can be converted by EtI into bromo-ethyl-theobromine $C_7H_6EtN_4O_2Br$, whence alcoholic KOH forms eth-oxy-ethyl-theobromine $C_7H_6EtN_4O_2(OEt)$ [153°] as needles. Boiling HCl converts this into EtCl and oxy-ethyl-theobromine $C_7H_6EtN_4O_2(OH)$, whence bromine and alcohol form the di-ethyl derivative of tri-oxy-di-hydro-ethyl-theobromine $C_7H_6EtN_4O_2(OH)(OEt)_2$ [152°]. This body on treatment with hot dilute HCl gives methylamine and apo-ethyl-theobromine (?); and with chlorine at −10° forms hypo-ethyl-theobromine $C_7H_9N_3O_3$ [142°].

Methyl-theobromine is CAFFEÏNE.

Ethyl-theobromine $C_7H_7EtN_4O_2$. [above 270°]. Formed from $C_7H_7AgN_4O_2$ and EtI (Philips, *B.* 9, 1308). Small crystals, m. sol. hot water. Weak base.

THEOPHYLLIN $C_7H_8N_4O_2$ *i.e.*

$\mathrm{CO}<\begin{matrix}\mathrm{NH.C:CH\ .NMe}\\ \mathrm{N{=}C.NMe.CO}\end{matrix}$. [264°]. Occurs in alcoholic extract of tea, from which it may be separated by means of its Ag salt (Kossel, *B.* 21, 2164). Monoclinic tables (containing aq, v. e. sol. warm water and very dilute ammonia. May be sublimed. When evaporated with chlorine-water it yields a scarlet residue, which is coloured violet by NH_3Aq. MeI converts its Ag salt into caffeïne. $KClO_3$ and HClAq yield di-methyl-alloxan.

Salt.—$AgC_7H_7N_4O_2\frac{1}{2}aq$. Amorphous pp., which may be crystallised from NH_3Aq.

THETINES. A name given by Crum-Brown and Letts to compounds of the form $CO_2H.CH_2.SR_2.OH$ or their anhydrides  $\begin{array}{l}\mathrm{CH_2{-}SR_2}\\ \mathrm{CO{-}O}\end{array}$ where R is a hydrocarbon radicle; *v.* DI-ETHYL-THETINE and DI-METHYL-THETINE.

THEVETIN $C_{54}H_{84}O_{24}3aq$. [170°]. S. ·8 at 14°. $\alpha = -85\cdot5°$. A poisonous glucoside occurring in the kernels of *Thevetia nereïfolia* (Blas, *J.* 1868, 768; De Vrij, *R. T. C.* 3, 167; Warden, *Rh.* [3] 12, 417). Crystalline powder, v. sol. hot water and alcohol, insol. ether. Sol. acids and alkalis. Lævorotatory. Conc. H_2SO_4 gives a dirty-brown colour. Decomposed by boiling dilute HClAq into glucose and theveresin $C_{48}H_{76}O_{17}2aq$, a white powder [140°], v. sl. sol. cold water, sol. alkalis.

THIACETIC ACID *v.* THIO-ACETIC ACID.

THIALDINE $C_6H_{13}NS_2$ *i.e.* $\mathrm{NH}\!<\!\begin{array}{l}\mathrm{CHMe.S}\\ \mathrm{CHMe.S}\end{array}\!>\!\mathrm{CHMe}$. Mol. w. 163. [43°]. Formed by passing H_2S for four hours into a solution of aldehyde-ammonia (1 pt.) in water (15 pts.), and a little NH_3Aq (Wöhler a. Liebig, *A.* 61, 2; Hofman, *A.* 103, 93; Brusewitz a. Cathander, *J. pr.* 98, 315). Monoclinic crystals (from ether-alcohol). May be distilled with steam. V. sl. sol. water, v. sol. alcohol, v. e. sol. ether. Boiling dilute H_2SO_4 forms thio-acetic aldehyde. $KMnO_4$ forms $CH_3.CH(SO_3K)_2$ (Guareschi, *B.* 11, 1384, 1692). Boiling $AgNO_3Aq$ forms aldehyde. MeI in ether forms crystalline $C_6H_{13}MeNS_2I$ (Hofmann, *A.* 103, 93). I in KI forms amorphous $(CHMe)_2S_4$ (Fassbender, *B.* 20, 460).

Salts.—B'HCl. Prisms, v. sol. water.—B'HBr.—B'HI.—$B'HNO_3$.—$B'H_2SO_4$. Prisms.—$B'H_3PO_4$ aq. Needles, v. sol. water.

THIAZOLE  $\mathrm{N}\!<\!\begin{array}{l}\mathrm{CH.S}\\ \mathrm{CH{:}CH}\end{array}$. (116·8° cor.). S.G. $\frac{17}{4}$ 1·1979; $\frac{17}{17}$ 1·1998. Formed by the action of boiling alcohol on the diazo-compound of amido-thiazole, obtained from di-chloro-di-ethyl oxide and thio-urea (Hantzsch a. Popp, *B.* 21, 2582; *A.* 250, 274). Formed also from  $\mathrm{N}\!<\!\begin{array}{l}\mathrm{CCl.S}\\ \mathrm{CH{:}CH}\end{array}$, and the corresponding μ-bromo-thiazole by reduction with zinc-dust and HOAc (Schatzmann, *A.* 261, 12). Mobile liquid, very volatile, hygroscopic, and highly refractive. Miscible with water, alcohol, and ether. Insol. KOHAq. Smells like pyridine. Neutral in reaction.—**Salts.**—$B'_2H_2PtCl_6$ 2aq.—$B'HAuCl_4$. [250°].—$B'C_6H_3N_3O_7$. [151°].—$B'HHgCl_3$. [104°].—$B'HgCl_2$. [204°]. Crystalline pp., sl. sol. water.

μ-Amido-thiazole  $\mathrm{N}\!<\!\begin{array}{l}\mathrm{C(NH_2).S}\\ \mathrm{CH{=}CH}\end{array}$. *Thiazoline. Thiazylamine.* [90°]. Formed by the action of chloro-acetic aldehyde on thio-urea (Traumann, *A.* 249, 36). Prepared by boiling $CH_2Cl.CHCl.OEt$ (1 pt.) with thio-urea (1 pt.) and water (5 pts.). Yellowish plates, sl. sol. water, alcohol, and ether. Strong base.—B'HCl aq. Needles.—$B'_2H_2PtCl_6$. Yellow tables.

Acetyl derivative. [203°]. Needles.

THIAZOLE-TRIAZOLE (so called) $\mathrm{CH}\!<\!\begin{array}{l}\mathrm{S{-}C{:}N}\\ \mathrm{CH.N.N}\end{array}\!>\!\mathrm{CH}$. Formed by the action of HClAq on methyl-nitroso-imido-thiazoline (Näf, *A.* 265, 123). Liquid, v. sol. water. Alkaline; reduces Fehling's solution. Nitrous acid reproduces nitroso-methyl-imido-thiazoline.—B'HCl 2aq. [220°]. Needles.—B'HBr 2aq.

THIENONE is DI-THIENYL KETONE.

DITHIENYL $C_8H_6S_2$ *i.e.* $C_4H_3S.C_4H_3S$. [83°]. (266° cor.). Formed on passing thiophene through a red-hot tube (Nahnsen, *B.* 17, 789, 2197). Plates (from alcohol). Conc. H_2SO_4 gives a reddish-brown solution with deep-green fluorescence. On warming with isatin and H_2SO_4 it gives a violet-blue colour.

Sulphonic acid $C_8H_5S_2(SO_3H)$. Got by heating with H_2SO_4 (20 pts.) at 100°. Yields a crystalline BaA'_2 aq.

Reference.—HEXA-BROMO-DITHIENYL.

THIENYL-ACETIC ACID $C_4H_3S.CH_2.CO_2H$. [76°]. Formed from $C_4H_3S.CH(OH).CO_2H$ [115°], HIAq, and P (Ernst, *B.* 19, 3281). Crystalline, sol. hot water, alcohol and ether.—$Ba'A_2$ (dried at 130°). Crystals.—AgA': pp.

Reference.—OXY-THIENYL-ACETIC ACID.

THIENYL-ACRYLIC ACID $C_7H_6SO_2$ *i.e.* $C_4H_3S.CH{:}CH.CO_2H$. [138°]. Formed by boiling thiophenic aldehyde with NaOAc and Ac_2O (Biedermann, *B.* 19, 1855). Needles (from water), sol. hot water and alcohol. $FeCl_3$ gives an amorphous orange pp.—AgA': white pp.

THIENYLAMINE *v.* AMIDO-THIOPHENE.

THIENYL-BROMO-ETHANE *v.* BROMO-THIENYL-ETHANE.

THIENYL-BROMO-ETHYLENE *v.* BROMO-THIENYL-ETHYLENE.

THIENYL BROMO-METHYL KETONE $C_4H_3S.CO.CH_2Br$. *ω-Bromo-acetothienone.* Formed by adding Br (2 at.) to thienyl methyl ketone (1 mol.) dissolved in CS_2 (Brunswig, *B.* 19, 2891). Pungent yellow oil, may be distilled *in vacuo*. V. sol. alcohol and ether. Solidified by cold. Alcoholic NH_3 forms a deep-blue colour. Oxidised to (α)-thiophenic acid [126·5°]. Aniline yields $C_4H_3S.CO.CH_2NHPh$ [80°].

Thienyl di-bromo-methyl ketone $C_4H_3S.CO.CHBr_2$. [c. 0°]. Formed from thienyl methyl ketone and Br. Pungent oil, almost insol. ligroïn.

(β)-THIENYL-CARBINOL $C_4H_3S.CH_2OH$. (207° cor.). Formed by shaking (β)-thiophenic aldehyde with aqueous potash (Biedermann, *B.* 19, 639). Liquid. HCl forms $C_4H_3S.CH_2Cl$, a pungent oil boiling with partial decomposition at 175°.

THIENYL CHLORO-ETHANE *v.* CHLORO-THIENYL-ETHANE.

THIENYL-CHLORO-ETHYLENE *v.* CHLORO-THIENYL-ETHYLENE.

(α)-THIENYL CHLORO-METHYL KETONE $C_4H_3S.CO.CH_2Cl$. [47°]. (259° cor.). Formed by chlorination of thienyl methyl ketone (Peter, *B.* 18, 539). Pungent white crystals. Yields (α)-thiophenic acid on oxidation.

THIENYL-ETHYL-AMINE C_6H_9NS *i.e.* $C_4H_3S.CHMe.NH_2$. (186°). Got by reducing the oxim of thienyl methyl ketone in alcoholic solution by adding sodium-amalgam and HOAc (Goldschmidt a. Schulthess, *B.* 20, 1700). Liquid, sol. water. Absorbs CO_2 from the air.—B'HOAc. Needles, v. e. sol. water.

Benzoyl derivative. [95°]. Needles.

THIENYL ETHYL KETONE $C_4H_3S.CO.C_2H_5$. *Propiothienone.* (228° cor.). Formed from propionyl chloride, thiophene, and $AlCl_3$ (Krekeler, *B.* 19, 677). Liquid. Hot conc. H_2SO_4 forms propionic and thiophene (*a*)-sulphonic acids Chromic acid mixture yields (*a*)-thiophenic acid

Oxim $C_4H_3S.CEt{:}NOH$. [56°].

THIENYL DIETHYL PHOSPHINE $(C_4H_3S)PEt_2$. (225°). Formed from thienyl-chloro-phosphine and $ZnEt_2$ in ether (Sachs, *B.* 25, 1517).

Ethylo-iodide $(C_4H_3S)PEt_3I$.

Methylo-iodide $(C_4H_3S)PEt_2MeI$. [122°]. White powder, v. sol. water insol. ether.

THIENYL-GLYCOLLIC ACID *v.* Oxy-thienyl-acetic acid.

(*a*)-THIENYL-GLYOXYLIC ACID $C_6H_4SO_3$ aq *i.e.* $C_4H_3S.CO.CO_2H$. [91°]. Formed by oxidising thienyl methyl ketone with alkaline $KMnO_4$ (Peter, *B.* 18, 537; Biedermann, *B.* 19, 637; Bradley, *B.* 19, 2115). Formed also, together with thiophene (*a*)-carboxylic acid, by oxidation of (*a*)-ethyl-thiophene by alkaline $KMnO_4$. Crystals (containing aq, possibly as $C_4H_3S.C(OH)_2.CO_2H$), v. sol. warm water. Melts at 59° when hydrated. May be extracted by ether, from its aqueous solution. If a drop of crude benzene, followed by H_2SO_4, be added to its solution in HOAc, a brown colour is formed, which on addition of more H_2SO_4 passes through blue-green, green, violet, red, and bluish-violet to blue.

Reactions.—1. On heating it splits up into CO_2 and thiophenic aldehyde.—2. On heating with di-methyl-aniline and $ZnCl_2$ it yields the leuco-base of a green dye $C_4H_3S.CH(C_6H_4NMe_2)_2$.—3. PCl_5 forms thiophenic chloride.

Salts.—BaA'_2 aq. Slender efflorescent needles, v. sol. water.—CaA'_2 2aq.—CuA'_2 2aq.—ZnA'_2 2aq.—AgA' aq: amorphous pp., probably $C_4H_3S.C(OH)_2.CO_2Ag$.

Methyl ether MeA'. [28·5°].

Ethyl ether EtA'. (265° uncor.). Oil.

Amide $C_4H_3S.CO.CO.NH_2$. [88°]. Needles, almost insol. water, v. sol. alcohol and ether.

Oxim $C_4H_3S.C(NOH).CO_2H$. [146°]. (Hantzsch, *B.* 24, 48). Slender white needles. Exhibits Liebermann's reaction (Bradley, *B.* 19, 2119).—$BaA'_2\,1\frac{1}{2}$aq.—AgA': amorphous pp.—MeA' [105°]. Converted by NaOMe and MeI into liquid $C_4H_3S.C(NOMe).CO_2Me$.—EtA'. [123°]. Needles.

Acetyl derivative of the oxim. [87°].

Phenyl-hydrazide $C_4H_3S.C(N_2HPh).CO_2H$. [165°]. Deep-yellow needles (from ether).

Reference.—Nitro-thienyl-glyoxylic acid.

THIENYL HEXYL KETONE $C_{11}H_{16}SO$ *i.e.* $C_4H_3S.CO.C_6H_{13}$. (304° cor.). Formed from thiophene, heptoyl chloride, and $AlCl_3$ in ligroïn (Schleicher, *B.* 19, 664). Yellow oil, yielding (*a*)-thiophenic acid on oxidation. Conc. H_2SO_4 forms thiophene (*a*)-sulphonic and heptoic acids.

Oxim [49°]. Crystals (from alcohol).

THIENYL-INDOLE $C_{12}H_9NS$ *i.e.*

$C_6H_4{<}\begin{matrix}CH\\NH\end{matrix}{>}C.C_4H_3S$. [162°]. Formed by heating the phenyl-hydrazide of thienyl methyl ketone with $ZnCl_2$ (Brunck, *A.* 272, 201). Light-yellow needles, insol. water, v. sol. ether, m. sol. alcohol. Colours pine-wood, moistened with HCl, bluish-violet. Yields $C_{12}H_3Br_6NS$ [278°] and $C_6H_5CH(C_{12}H_8NS)_2$ [245°].—$B'C_6H_3N_3O_7$ [187°]. Dark red plates, v. sol. alcohol.

Nitrosamine $C_{12}H_8(NO)NS$. [241°].

DI-THIENYL KETONE $(C_4H_3S)_2CO$. [88°]. (326° uncor.). Formed from thiophene, $COCl_2$, and $AlCl_3$. Obtained also by distilling calcium *a*-thiophenate (Gattermann, *B.* 18, 3012). Needles or plates, sol. alcohol.

Phenyl-hydrazide [137°].

THIENYL MERCAPTAN $(C_4H_3S).SH$. (166°). Got by reducing thiophene (*a*)-sulphinic acid with zinc and HClAq (Biedermann, *B.* 19, 1616). Got also in small quantity from succinic acid and P_2S_5 (V. Meyer a. Neure, *B.* 20, 1757). Stinking oil, volatile with steam.—$AgS.C_4H_3S$.

Acetyl derivative $(C_4H_3S).SAc$. (231°).

Methyl ether $(C_4H_3S)SMe$. (186°).

DI-THIENYL METHANE $C_9H_8S_2$ *i.e.* $CH_2(C_4H_3S)_2$. (267°). Got by adding H_2SO_4 to a solution of thiophene and methylal in HOAc (Peter, *B.* 17, 1345). Oil, smelling like oranges. Volatile with steam. Gives a red colour with isatin and H_2SO_4.

(*a*)-THIENYL METHYL KETONE C_6H_6SO *i.e.* $C_4H_3S.CO.CH_3$. *Acetothienone.* (213° cor.). S.G. $\frac{24}{24}$ 1·167. Formed from thiophene, AcCl, and $AlCl_3$ (Peter, *B.* 17, 2643; Biedermann, *B.* 19, 636; Bradley, *B.* 19, 2115). Formed also from $C_4H_3(HgCl)S$ and AcCl (Volhard, *A.* 267, 178). Liquid, smelling like acetophenone. Gives a blue colour with isatin and H_2SO_4. Oxidised by $KMnO_4$ to (*a*)-thienyl-glyoxylic and thiophenic acids. Mercuric chloride and NaOAc form the compound $(CH_3.CO.C_4H_3S)HgCl_2$ crystallising in white needles. Oxalic ether (1 mol.) and NaOEt give $C_4H_3S.CO.CH_2.CO.CO_2Et$ [42°], which forms large yellow crystals, converted by boiling alcoholic hydroxylamine hydrochloride into the compound

$C_4H_3S.C{<}\begin{matrix}CH{:}C.CO_2Et\\N\ .\ O\end{matrix}$ or

$CO_2Et.C{<}\begin{matrix}CH{:}C.C_4H_3S\\N\ .\ O\end{matrix}$ crystallising in colourless needles [48°] (Angeli, *B.* 24, 232).

Oxim $C_6H_6S(NOH)$. [112°].

Phenyl-hydrazide $C_6H_6S(N_2HPh)$. [96°].

Reference.—Bromo-, Chloro-, Iodo-, and Nitro-thienyl methyl ketone.

THIENYL PHENYL - AMIDO - METHYL KETONE $C_4H_3S.CO.CH_2.NHPh$. [80°]. Formed by mixing $C_4H_3S.CO.CH_2Br$ with aniline in alcohol (Brunswig, *B.* 19, 2892). Plates. Yields a nitrosamine $C_4H_3S.CO.CH_2.NPh(NO)$ [81°], and acetyl derivative $C_4H_3S.CO.CH_2.NPhAc$ [142°].

THIENYL PHENYL KETONE $C_4H_3S.CO.C_6H_5$. [55°]. (c. 300°). Formed by the action of $AlCl_3$ on a mixture of thiophene and BzCl (Comey, *B.* 17, 790). Formed also by heating $C_4H_3(HgCl)S$ with BzCl at 100° (Volhard, *A.* 267, 179). Long needles (from dilute alcohol), insol. water. Gives a blue colour on heating with isatin and H_2SO_4. Yields thiophene and benzoic acid on heating with soda-lime.

Oxims $C_4H_3S.CPh{:}NOH$. Hydroxylamine forms two stereo-isomeric (?) oxims [93°] and [114°] (Hantzsch, *B.* 23, 2332; 24, 59).

THIENYL-PHENYL-METHANE $CH_2Ph.C_4H_3S$. (265°). Formed by the action of H_2SO_4 on a mixture of thiophene and benzyl alcohol dissolved in HOAc (Peter, *B.* 17, 1346). Liquid with fruity smell, volatile with steam. Gives a red colour with isatin and H_2SO_4.

Thienyl-di-phenyl-methane $CHPh_2.C_4H_3S$. [63°]. (330°-340°). Formed from thiophene, di-phenyl-carbinol, and P_2O_5 (Levi, *B.* 19, 1624).

Plates (from alcohol) or needles (from ligroïn), v. sol. HOAc, alcohol, and ether. Crystallises from cold benzene in needles $C_{17}H_{14}SC_6H_6$ [48°].

THIENYL ISOPROPYL KETONE $C_4H_3S.CO.CHMe_2$. (232° cor.). Formed from isobutyryl chloride, thiophene, and $AlCl_3$ (Krekeler, *B.* 19, 675). Liquid. Yields (*α*)-thiophenic acid on oxidation. Fuming H_2SO_4 reacts with formation of the sulphonic acid $C_4H_2(SO_3H)S.CO.CHMe_2$, which yields the salts BaA'_2, PbA'_2xaq, and is converted by phenyl-hydrazine into $C_4H_2(SO_3N_2H_4Ph)S.C(N_2HPh).CHMe_2$, crystallising from hot water in plates.

Oxim $C_4H_3S.C(NOH).CHMe_2$. [108°]. Pearly plates (from dilute alcohol).

THIENYL STYRYL KETONE *v.* STYRYL THIENYL KETONE.

THIENYL DISULPHIDE $(C_4H_3S)_2S_2$. [56°]. Formed by atmospheric oxidation of a solution of thienyl mercaptan in alcoholic NH_3 (Meyer a. Neure, *B.* 20, 1757). Needles.

THIENYL SULPHOCYANO - METHYL KETONE $CH_2(SCy).CO.C_4H_3S$. [88°]. Formed from $CH_2Br.CO.C_4H_3S$ and KSCy in alcohol (Brunswig, *B.* 19, 2893). Plates (from ether), sl. sol. water and ligroïn, m. sol. alcohol.

DI-THIENYL-THIOPHENE $C_4SH_2(C_4SH_3)_2$. [147°]. (357°). V.D. 8·6. One of the products of the passage of benzene and sulphur-vapour through a red-hot tube (Renard, *C. R.* 112, 49). Yellowish needles (from alcohol), m. sol. benzene. H_2SO_4 forms a rose-coloured solution, turned violet and finally blue on heating. Fuming H_2SO_4 at 120° forms a trisulphonic acid, which yields $(C_{12}H_5S_3(SO_3)_3)_2Ca_3$ as an amorphous powder, v. sol. water. Fuming HNO_3 at 160° forms $C_{12}H_8S_2O_4$ [313°], crystallising in white plates, v. sl. sol. benzene. Br forms $C_{12}H_5Br_3S_3$ [282°], and amorphous $C_{12}H_8Br_6S_3$.

THIENYL TOLYL KETONE $C_{12}H_{10}SO$ *i.e.* $C_6H_4Me.CO.C_4H_3S$. Formed from *o*-toluic chloride, thiophene, and $AlCl_3$ (Ernst, *B.* 19, 3279). Oil. Yields an oily oxim.

THIO-. This prefix is employed to denote the replacement of O by S. Most inorganic salts of thio- acids are described under the heading of the oxy-salts; thus *thio-carbonates* are described under CARBONATES. In some cases thio- salts are described under the heading of the characteristic element of the salts: *thio-arsenates* are to be found under ARSENIC. Certain thio -salts are described under headings placed in their strictly alphabetical position; for instance, THIOSULPHATES. *Thiocyanides* are described as SULPHOCYANIDES.

The following addition should be made to the sub-article THIO-OXYORTHOPHOSPHATES (p. 147). By heating metallic chlorides or sulphides with excess of P_2S_5 Glatzel has prepared a number of *tetrathio-oxyorthophosphates, i.e.* salts of the hypothetical acid H_3PS_4 (*Zeit. für anorg. Chemie*, 4, 186). These salts are crystalline—generally green to black in colour; they are burnt in air, giving off SO_2; some are decomposed to sulphides and P_2S_5, but the mercuric and arsenic salts distil unchanged when heated out of contact with air. These salts are insol. in dilute acids; they are decomposed by strong acids. G. isolated the thiophosphates of Sb, As, Bi, Cd, Cu(ous), Fe(ous), Pb, Mn, Hg(ic), Ni, Ag, Tl, Sn(ous), and Zn; he could not obtain the salts of Ca, K, Na, or Sr.

M. M. P. M.

THIOACETAMIDE $CH_3.CS.NH_2$. [108°]. Formed from acetonitrile and H_2S (Bernthsen, *A.* 192, 46), and from acetamide and P_2S_5 (Hofmann, *B.* 11, 340). Monoclinic plates, v. sol. water and alcohol, m. sol. ether. HgO forms HgS. $AgNO_3$ gives Ag_2S. $CuSO_4$ and $Pb(OAc)_2$ give, on boiling, CuS and PbS. $HgCl_2$ forms a crystalline compound. α-bromo-acetoacetic ether forms $CH_3.C(NH).S.CH_2.CO.CH_2.CO_2Et$ [94°], and finally $S{<}\begin{matrix}CMe{:}N\\CH{:}C.CH_2.CO_2Et\end{matrix}$ (239°), the ether of methyl-thiazyl-acetic acid [121°] (Steude, *A.* 261, 36). The ether melting at 94° is converted by warming with water into the compound $CH_3.CO.S.CH_2.CO.CH_2.CO_2Et$ (155° at 15 mm.), whence H_2SO_4 forms an acid $C_6H_8SO_2$ [168°].

THIO-ACETIC ACID C_2H_4SO *i.e.* $CH_3.CO.SH$. Mol. w. 76. (93°). S.G. ^{10} 1·074. Prepared by distilling acetic acid with P_2S_5 (Kekulé, *A.* 90, 311; Ulrich, *A.* 109, 272; Kekulé a. Linnemann, *A.* 123, 273). Obtained also from AcCl and KSH (Jacquemin a. Vosselmann, *J.* 1859, 354), by heating lead acetate with $Na_2S_2O_3$ (Fröhde, *Z.* 1866, 543), and by the action of KSH on an alcoholic solution of PhSAc (Kekulé, *Z.* [2] 3, 196). Colourless liquid, turning yellow on keeping. Smells like acetic acid and H_2S. Not solid at −17°. M. sol. warm water, v. sol. alcohol and ether. Violently attacked by fuming HNO_3. PCl_5 yields AcCl, $PSCl_3$ and HCl. Its neutral solutions give pps. with $AgNO_3$ and $HgCl_2$, which quickly turn black. Molten $ZnCl_2$ forms $CMe{:}S_3{:}CMe$ [225°], which may be crystallised from hot alcohol (Bongartz, *B.* 19, 2182). HCl passed into a mixture of thio-acetic acid and benzoic aldehyde forms $(CH_3.CO.S)_2CHPh$ [148°], crystallising from hot ether in slender needles.

Salts.—KA'. Crystals, v. sol. water and alcohol.—NaA' ½aq.—BaA'_2 3aq.—SrA'_2 2aq.—CaA'_2 2aq.—PbA'_2. Silky needles (from hot water or alcohol). Quickly decomposes, with separation of PbS.

Methyl ether MeA'. (96°). Formed by heating AcBr with Me_2S at 100° (Cahours, *Bl.* 25, 562; Wallach a. Bleibtreu, *B.* 12, 1062). Formed also from AcCl and $Pb(SMe)_2$ (Obermeyer, *B.* 20, 2920).

Ethyl ether EtA'. (116° i.V.). Formed from AcCl and NaSEt (Saytzeff, *Z.* [2] 4, 642; Beckmann, *J. pr.* [2] 17, 461). Formed also from PhOAc and NaSEt (Seiffert, *J. pr.* [2] 31, 468). Colourless liquid, with alliaceous odour. Oxidised by $AgMnO_4$ to acetic acid and ethane sulphonic acid.

n-Propyl ether PrA'. (136°).

Isopropyl ether PrA'. (126°).

Isobutyl ether CH_2PrA'. (149°).

Anhydride v. ACETYL SULPHIDE.

Thio-acetic acid $CH_3.CS.OH$.

Amide v. THIOACETAMIDE.

Anilide $CH_3.CS.NHPh$. [75°]. Formed from $CH_3.CCl{:}NPh$ and H_2S (Leo, *B.* 10, 2134). Prepared by heating acetanilide with P_2S_5 at 100° (Hofmann, *B.* 11, 339; Jacobsen, *B.* 19, 1071). Yellowish needles (from water). Sol. NaOHAq and reppd. by acids. On oxidation with alkaline K_3FeCy_6 it yields ethenyl-amido-phenyl mercaptan. MeI forms C_8H_8NSMeI or $(CH_3.CS.NPhMe)HI$ [139°], which yields an aqueous solution from which $AgNO_3$ at once ppts. AgI, and which is converted by AgCl into $C_8H_9NSMeCl$, whence $(C_8H_9NSMeCl)_2PtCl_4$ may be got (Bernthsen, *A.* 192, 56). NaOEt forms $CH_3.C(SNa):NPh$, whence MeI yields the ether $CH_3.C(SMe):NPh$ (245°) (Wallach a. Bleibtreu, *B.* 12, 1061; 13, 529), which is decomposed by MeI at 100° into methyl thioacetate and methylaniline. NaOEt and EtBr yield the corresponding $CH_3.C(SEt):NPh$, a heavy oil, insol. alkalis, split up by warm HClAq into thioacetic ether and aniline. 'Ethyl-iso-thioacetanilide' yields $(C_{10}H_{13}NS)_2H_2PtCl_6$.

Methyl anilide $CH_3.CS.NMePh$. [59°]. (290°). Formed from AcNMePh and P_2S_5 (Wallach, *B.* 13, 528). Monoclinic tables, v. sol. alcohol.

o-Toluide $CH_3.CS.NHC_7H_7$. [68°]. Yields $CH_3.C(SEt):NC_6H_4Me$ (262°), an oil which reacts with bases forming amidines and EtSH.

p-Toluide [132°]. Yields oily $CH_3.C(SEt):NC_7H_7$. (273°) (Wallach a. Wüsten, *B.* 16, 147).

Xylidide $CH_3.CS.NHC_6H_3Me_2$. [80°] (G.); [95°] (Jacobsen). Formed by heating acetylxylidine with P_2S_5 on the water-bath (Gudeman, *B.* 21, 2551).

ψ-Cumidide $CH_3.CS.NHC_6H_2Me_3$. [114°]. Prisms (Jacobsen a. Elley, *B.* 22, 907).

(α)-*Naphthalide* $CH_3.CS.NHC_{10}H_7$. [96°]. Tables. Formed from naphthyl-acetamidine and CS_2 (Bernthsen a. Trompetter, *B.* 11, 1760).

(β)-*Naphthalide.* [146°]. Needles or plates (Jacobsen, *B.* 21, 2627). Oxidised by K_3FeCy_6 to $C_{10}H_6{<}\begin{matrix}N\\S\end{matrix}{>}CMe$ [81°].

Tri-thio-ortho-acetic acid $CH_3.C(SH)_3$.

Ethyl ether $CH_3.C(SEt)_3$. Formed from mercaptan, $CHCl_3$, and NaOH at 100° (Laves, *B.* 25, 354). Brownish liquid. Oxidised by $KMnO_4$ and H_2SO_4 to the trisulphone.

Benzyl ether $CH_3.C(SC_7H_7)_3$. [46°]. Formed from benzyl mercaptan, $CHCl_3$, and (2 p.c.) NaOHAq (Laves). Crystals, v. sol. $CHCl_3$, m. sol. alcohol.

THIO-ACETIC ALDEHYDE. On passing H_2S into an aqueous solution of aldehyde, crude thioacetic aldehyde separates as an oil, which solidifies at −8°, and then melts at −2°. This oil [V.D. 60 (H = 1)] is a mixture of thioacetic aldehyde and its polymerides, and may be represented, in a state of vapour, as $C_2H_4S + C_6H_{12}S_3$ (Pinner, *B.* 4, 258; Klinger, *B.* 9, 1893; 10, 1877; 11, 1023). On distillation, or on passing HCl through the liquid, it is converted into the polymeric tri-thio-tri-acetic aldehyde.

Tri-thio-tri-acetic aldehyde $C_6H_{12}S_3$. Mol. w. 180. [46°]. V.D. 89·7 (calc. 90) (Hofmann, *B.* 3, 589; *Z.* [2] 6, 699). Formed by passing H_2S into an acid solution of aldehyde (Klinger; *cf.* Weidenbusch, *A.* 66, 152; Crafts, *C. R.* 54, 1279). Formed also from paraldehyde and H_2S. White needles, sol. alcohol and ether. Smells like garlic. $AgNO_3$ added to its alcoholic solution forms crystalline $C_6H_{12}S_3 2AgNO_3$. Chlorine forms ethylidene chloride (Pinner, *A.* 179, 21). $KMnO_4$ oxidises it to $CH_3.CH(SO_3H)_2$ and oxysulphides, including $C_6H_{12}S_3O_6$ [217°], which crystallises from hot water in needles (Guareschi, *A.* 222, 301). Zinc permanganate produces $C_6H_{12}S_3O_6$, which does not melt below 245°, $C_6H_{12}S_3O_2$ [112°–116°], and $C_6H_{12}S_3O_4$ [228°–231°] (*cf.* Baumann, *B.* 26, 2074).

(α)-**Tri-thio-tri-acetic aldehyde** $C_6H_{12}S_3$ *i.e.*  $CHMe{<}\begin{matrix}S.CHMe\\S.CHMe\end{matrix}{>}S$. [102°]. (247°). V.D. 6 (air = 1). Formed by the long-continued action of H_2S on a mixture of equal parts of water, conc. HClAq and aldehyde. Long prisms (from acetone). Reduced by HI to Et_2S_2. Oxidised by $KMnO_4$ to $C_6H_{12}S_3O_4$ [284°] (S. 1 at 100°; ·116 at 20°), and $C_6H_{12}S_3O_6$ or  $C_2H_4{<}\begin{matrix}SO_2.C_2H_4\\SO_2.C_2H_4\end{matrix}{>}SO_2$, which softens at 340° and is converted by MeI into $C_9H_{18}S_3O_6$ [302°]. Yields crystalline $C_6H_{12}S_3AgNO_3$ and $C_6H_{12}S_3 3AgNO_3$.

(β)-**Tri-thio-tri-acetic aldehyde** $C_6H_{12}S_3$. [126°]. (247°). V.D. 6·0. Formed by the action of AcCl or H_2SO_4 on its (α)-isomeride. Prepared by passing H_2S into a mixture of aldehyde (1 pt.) and alcohol previously saturated with HCl (3 pts.) (Baumann a. Fromm, *B.* 22, 2600; 26, 2074). Long needles (from alcohol). Oxidised by $KMnO_4$ to the same sulphones as the (α)-isomeride. Reacts with MeI, yielding SMe_3I. Distillation with Cu forms ψ-butylene. Forms crystalline $C_6H_{12}S_3AgNO_3$ and $C_6H_{12}S_3 3AgNO_3$.

(γ)-**Tri-thio-acetic aldehyde** $C_6H_{12}S_3$. [76°]. (242°). Formed, together with $C_5H_9NS_3$, by boiling thialdine sulphocyanide with water (Marckwald, *B.* 19, 1827; 20, 2817). Needles (from alcohol), insol. water, v. sol. ether and CS_2. Volatile with steam. Sol. conc. H_2SO_4 and reppd. by water. When mixed with EtI (4 pts.) and left for some weeks it suddenly changes to a crystalline mass of the (β)-isomeride. $C_6H_{12}S_3 3AgNO_3$. Plates, v. sol. water. Yields Ag_2S on boiling with alcohol.

'**Di-thialdehyde thiocarbimide**' $C_5H_9NS_3$. [138°]. Formed as above. Needles, m. sol. ether. Yields $C_5H_9NS_3AgNO_3$ v. sol. water, and $(C_5H_9NS_3)_2PtCl_4$.

Di-thio-acetic orthoaldehyde. *Ethyl ether* $CH_3.CH(SEt)_2$. Formed by passing HCl into a mixture of acetic aldehyde and EtSH (Baumann, *B.* 18, 884). Mobile oil.

THIOACETIC ANHYDRIDE *v.* ACETYL SULPHIDE.

THIO-ACETONE $CH_3.CS.CH_3$. A product of the action of H_2S on acetone, and formed also when $CMe_2(SEt)_2$ is heated above 160° (Baumann a. Fromm, *B.* 22, 2592). Volatile oil, with very persistent and disagreeable smell. Unstable.

Duplo-thioacetone $C_6H_{12}S_2$ *i.e.* $S{<}\begin{matrix}CMe_2\\CMe_2\end{matrix}{>}S$. V.D. 5·08 (calc. 5·11). (184° cor.). Formed by heating acetone with P_2S_5 at 125° (Wislicenus, *Z.* [2] 5, 324; Autenrieth, *B.* 20, 375). Formed also by heating tri-thio-tri-acetone at 200° for some time (Fromm a. Baumann, *B.* 22, 1043). Oil. Its alcoholic solution gives a white pp. with $HgCl_2$. Reduced by sodium-amalgam to isopropyl mercaptan (Spring, *Bl.* [2] 40, 69). Oxidised by a 5 p.c. solution of $KMnO_4$ to the disulphone  $SO_2{<}\begin{matrix}CMe_2\\CMe_2\end{matrix}{>}SO_2$ [220°–225°].

Tri-thio-tri-acetone $C_9H_{18}S_3$ *i.e.*  $S{<}\begin{matrix}CMe_2.S\\CMe_2.S\end{matrix}{>}CMe_2$. [24°]. (130° at 15 mm.). Formed, together with $C_{13}H_{28}S_4$ [171°], by passing H_2S into a cooled mixture of acetone and conc. HClAq (Fromm a. Baumann, *B.* 22, 1037, 2597). Needles (from alcohol); insol. water, v. sol. alcohol and ether. Boils, with much decomposition, at 225°-230°. Gives a white pp. with $HgCl_2$ and a yellow pp. with lead acetate. Potassium permanganate and H_2SO_4 yield the trisulphone  $SO_2<\begin{matrix}CMe_2.SO_2\\CMe_2.SO_2\end{matrix}>CMe_2$ [302°] and  $S<\begin{matrix}CMe_2.SO_2\\CMe_2.SO_2\end{matrix}>CMe_2$ [208°].

Duplo-di-thio-acetone $(Me_2CS_2)_2$. [98°]. (c. 243°). Formed from acetone and yellow ammonium sulphide in the cold (Willgerodt, *B.* 20, 2467). Dimetric crystals, *a*:*c* = 1: ·868, insol. water. Partially decomposed on distillation.

Di-thio-orthacetone. *Di-ethyl ether* $CMe_2(SEt)_2$. *Acetone-ethyl-mercaptol.* (191°). Formed by passing dry HCl into a mixture of acetone (1 pt.) and mercaptan (2 pts.) (Baumann, *B.* 18, 887). Liquid.

Di-phenyl ether $CMe_2(SPh)_2$; *v.* DI-PHENYL-PROPYLIDENE DISULPHIDE.

THIOACETONURAMIC ACID *v.* ACETONYL THIOCARBAMATE.

THIO-ACETOPHENONE $C_6H_5.CS.CH_3$. [119·5°]. Formed by the action of alcoholic ammonium sulphide on acetophenone (Engler, *B.* 11, 930). Colourless leaflets or needles, insol. water, sl. sol. alcohol, v. sol. ether. May be sublimed.

THIO-ACETYL-TOLUIDINE *v.* *Toluide of* THIO-ACETIC ACID.

THIO-ALLOPHANIC ACID. *Ethyl ether* $C_4H_8N_2SO_2$ *i.e.* $NH_2.CO.NH.CO.SEt$. [180°]. Formed by heating urea with Cl.CO.SEt at 80°-90° (Peitzsch a. Salomon, *J. pr.* [2] 7, 477). Pearly needles (from water), v. sl. sol. cold water and alcohol. Aqueous NH_3 at 100° forms biuret and mercaptan. Boiling baryta-water gives allophanic acid and mercaptan. Aniline yields di-phenyl-biuret and mercaptan.

Isoamyl ether $NH_2.CO.NH.CO.SC_5H_{11}$. [176°]. Needles (Schöne, *J. pr.* [2] 32, 251). AcCl yields an acetyl derivative [85°].

Phenyl ether [218°] (Gattermann, *A.* 244, 43).

Isothio-allophanic ether $NH_2.CS.NH.CO_2Et$. [170°-175°]. Formed by the action of thio-urea on $COCl.CO_2Et$ (Peitzsch, *B.* 7, 896). Prisms (from alcohol).

Di-thio-allophanic ether $NH_2.CS.NH.CO.SEt$. Formed from KSCy, alcohol, and HCl (Blankenhorn, *J. pr.* [2] 16, 358). Pearly prisms, insol. cold water, sol. hot ether. Alcoholic NH_3 at 150° forms thio-urea. Baryta-water yields mercaptan, CO_2, and thio-urea.

DI-THIO-AMMELIDE $C_3H_4N_4S_2$ *i.e.* $C_3N_3(NH_2)(SH)_2$. S. ·3 at 100°. Formed by boiling pseudosulphocyanogen $C_3HN_3S_3$ with KSH or ammonium sulphide solution (Jamieson, *A.* 59, 339; Ponomareff, *J. R.* 8, 222). Small needles, nearly insol. cold water, alcohol and ether, v. sol. aqueous ammonium sulphocyanide. Acid in reaction, decomposing carbonates.

Reactions.—1. Yields cyanuric acid when heated with HClAq.—2. NH_3Aq forms melamine $C_3H_6N_6$ by heating in a sealed tube.

Salts.—$NaHA''1\frac{1}{2}aq$. Tables.—$KHA''2aq$. White prisms, v. e. sol. water and alcohol.—$MgH_2A''_2 6aq$.—$CaH_2A''_2 2aq$.—$BaH_2A''_2 5aq$.—$BaH_2A''_2 6aq$. Monoclinic crystals, sl. sol. cold water.—$SrH_2A''_2 4aq$.—$AgHA''$. Flocculent pp., insol. water.

Methyl ether $C_3N_3(NH_2)(SMe)_2$. [200°]. Formed by heating $C_3N_3(SMe)_3$ with alcoholic NH_3 for five hours at 100° (Hofmann, *B.* 18, 2756). Trimetric tables, v. sl. sol. water, v. sol. alcohol. Boiling conc. HClAq forms MeSH, cyanuric acid, and NH_3.—$B'HAuCl_4$. Needles.

Ethyl ether Et_2A''. [112°]. Formed by heating tri-thio-cyanuric ether with alcohol NH_3 at 180° (Klason, *J. pr.* [2] 33, 298). Trimetric prisms. Converted by acids into ammelide.

Isoamyl ether $(C_5H_{11})_2A''$. [82°].

Di-thio-methyl-ammelide *di-methyl ether* $Cy_3(NHMe)(SMe)_2$. [175°]. Formed by heating $Cy_3(SMe)_3$ with aqueous $NMeH_2$ (Hofmann, *B.* 18, 2761). Needles or prisms (from dilute alcohol).

THIO-AMMELINE $C_3H_5N_5S$ *i.e.*  $C(SH)<\begin{matrix}N.C(NH_2)\\N:C(NH_2)\end{matrix}>N$. S. ·77 at 100° (K.). Formed by adding HCl to an aqueous solution of dicyan-diamide and ammonium sulphocyanide at 100° (Rathke, *B.* 18, 3106; 20, 1059; 23, 1675). Formed also from $C_3N_3(NH_2)_2Cl$ and KSH (Klason, *J. pr.* [2] 33, 296) and by heating ψ-sulphocyanogen with conc NH_3Aq at 100° (Ponomareff, *C. R.* 80, 1384). Needles, sl. sol. hot water, v. sol. acids and alkalis. Yields a canary-yellow pp. on boiling with ammoniacal $CuSO_4$. Conc. HClAq at 130° yields cyanuric acid, H_2S, and NH_3. Ethylene bromide forms crystalline $C_5H_7N_5SHBr$. Conc. NH_3Aq at 200° forms melamine. Boiling NaOHAq yields ammeline. Ammoniacal silver nitrate ppts. $C_3H_4N_5SAg$ and $C_3H_3N_5SAg_2$. Bromine added to a solution of thio-ammeline in HBrAq forms $S_2(C_3N_3(NH_2)_2)_2$, which dissolves in alkalis, and is split up by boiling with acids into ammeline, thio-ammeline, and S.

Salts.—$B'HNO_3$. Needles.—$B'_2H_2SO_4 3aq$.—$B'_2H_2C_2O_4 aq$. Needles, v. sl. sol. cold water.

Methyl ether MeA'. [268°]. Formed by heating tri-methyl tri-thiocyanurate for five hours with conc. alcoholic NH_3 at 160° (Hofmann, *B.* 18, 2757). Tables (from water).—$B'_2H_2PtCl_6$.

Ethyl ether EtA'. [165°].

Isoamyl ether $C_5H_{11}A'$. [178°].

Reference.—TRI-PHENYL-THIO-AMMELINE.

THIO-ANILINE *v.* DI-AMIDO-DI-PHENYL SULPHIDE.

THIOANISOIC ACID (so called) $C_{10}H_{14}SO_4$. Got by boiling anethol with HNO_3 (S.G. 1·1), distilling the product and shaking the fraction 215°-245° with conc. $NaHSO_3Aq$ and some alcohol (Städeler a. Wächter, *A.* 116, 163). Crystalline (containing 2aq), v. e. sol. water, alcohol, and ether.—$NH_4A'aq$.—$NaA'aq$. S. 15 in the cold.—$BaA'_2 3aq$. S. 8·5 in the cold.—$CaA'_2 2aq$.—$MgA'_2 5aq$.—AgA'. Plates, m. sol. water.

THIOBENZAMIDE *v.* *Amide* of THIOBENZOIC ACID.

(*a*)-**THIO-BENZOIC ACID** $C_6H_5.CO.SH$. Mol. w. 138. [c. 24°].

Formation.—1. From BzCl and alcoholic K_2S (Engelhardt a. Latschinoff, *Z.* [2] 4, 353).—2. By boiling EtOBz, PhOBz, and Bz_2O with alcoholic KSH.

Properties.—Yellow oil or white crystalline mass with unpleasant smell, volatile with steam. Decomposed by distillation. V. sol. alcohol and ether. Its solutions, when exposed to air, deposit crystals of Bz_2S_2. Nitric acid also oxidises it to benzoyl disulphide. A neutral solution gives with $CuSO_4$ a greenish-yellow pp., turning bright red; the pp. then containing Bz_2S_2.

Salts.—KA'. Large prisms (from alcohol), v. sol. water.—NaA'.—BaA'_2*x*aq. Laminæ (from alcohol).—PbA'_2.—AgA'. Yellowish-white pp.

Methyl ether C_6H_5.COSMe. (232°). Formed from $Pb(SMe)_2$ and BzCl (Obermeyer, *B.* 20, 2922).

Ethyl ether EtA'. (243°). Formed by the action of BzCl on $Pb(SEt)_2$ in presence of ether (Tütscheff, *Petersb. Acad. Bull.* 5, 295), and got also by boiling AgA' and EtI, and from PhOBz and NaSEt (Seiffert, *J. pr.* [2] 31, 471). Oil, with unpleasant smell, sol. alcohol and ether. Boiling alcoholic KOH forms KOBz and KSEt. Alcoholic KSH yields KSBz and KSEt. Oxidised by $AgMnO_4$ to benzoic and ethane sulphonic acids (Beckmann, *J. pr.* [2] 17, 464).

Isoamyl ether $C_5H_{11}A'$. (271°).

Phenyl ether PhS.Bz. [56°]. Formed from phenyl mercaptan and BzCl (Schiller a. Otto, *B.* 9, 1635). Needles (from benzene).

Di-nitro-phenyl ether $C_6H_3(NO_2)_2A'$. [118°]. Formed from (α)-chloro-*m*-di-nitrobenzene, alcoholic KSH, and BzCl (Willgerodt, *B.* 18, 328). Needles (from alcohol).

Benzyl ether C_7H_7A'. [39·5°]. Formed from benzyl mercaptan and BzCl (Otto a. Lüders, *B.* 13, 1285). Triclinic crystals, yielding $PhCH_2.SO_3H$ on oxidation.

p-Tolyl ether C_7H_7A'. [75°] (S. a. O.).

Anhydride v. BENZOYL SULPHIDE.

(β)-Thio-benzoic acid C_6H_5.CS.OH. Formed by boiling thiobenzoic aldehyde with nitric acid (S.G. 1·3) (Fleischer, *A.* 140, 234). Needles (containing ½aq), sol. alcohol and benzene. More sol. hot water than benzoic acid. When heated strongly it blackens without melting.—BaA'_2 4aq. Small nodules, v. sol. water and ppd. by alcohol.

Amide $C_6H_5.CS.NH_2$. *Thiobenzamide.* [116°]. Formed by passing H_2S into an alcoholic solution of benzonitrile containing a little NH_3, and heating on a water-bath (Cahours, *C. R.* 27, 329; Bernthsen, *B.* 10, 1241; *A.* 192, 49; Gabriel a. Heymann, *B.* 23, 157). Formed also by heating benzylamine (2 mols.) with S (1 mol.) at 180° (Wallach, *A.* 259, 304). Long needles (from hot water). Decomposed by HgO, yielding HgS and benzonitrile. Sodium-amalgam acting on its alcoholic solution forms amorphous thiobenzoic aldehyde, benzonitrile, benzylamine, and benzoic aldehyde. Iodine added to its alcoholic solution reacts with formation of di-benzenyl-azo-sulphim  $C_6H_5.C{<}\genfrac{}{}{0pt}{}{N.S}{N}{>}C.C_6H_5$, crystallising in long colourless needles [90°] converted by boiling H_2SO_4 into a base $C_{14}H_{14}N_2$ [71°], which yields $B'_2H_2PtCl_6$ (Hofmann, *B.* 2, 645; *B.* 25, 1587; Wanstrat, *B.* 6, 335). Zinc and HCl reduce thiobenzamide in alcoholic solution to benzylamine. Hydroxylamine forms $C_6H_5.C(NOH).NH_2$. Ethylene bromide at 100° forms the compound $C_2H_4(S.C(NH)C_6H_5)_2 2HBr$ [233°] decomposed by boiling water into $C_2H_4(SBz)_2$ (Gabriel a. Heymann, *B.* 24, 783). Chloral (1 mol.) forms, on warming, a compound $C_9H_8Cl_3NSO$ or $C_6H_5.CS.NH.CH(OH).CCl_3$ (?) crystallising in silky plates [104°], sl. sol. water, v. sol. alcohol (Spica, *G.* 16, 182).

Anilide C_6H_5.CS.NHPh or C_6H_5.C(SH):NPh. *Thiobenzanilide.* [102°]. Formed by the action of P_2S_5 (1 pt.) on benzanilide (2 pts.), and by heating phenyl-benzamidine or *s*-di-phenyl-benzamidine CPh(NPh)(NPhH) with H_2S or with CS_2 (Bernthsen, *B.* 11, 503; *A.* 192, 31). Formed also by passing H_2S into a solution of C_6H_5.CCl:NPh in benzene (Leo, *B.* 10, 2133), and from benzophenone oxim and P_2S_5 (Dodge, *A.* 264, 184). Obtained by heating benzyl-aniline (1 mol.) with S (2 at.) at 220° as long as H_2S escapes (Wallach, *A.* 259, 301). Thin prisms (from EtOAc), nearly insol. boiling water, v. sol. alcohol and ether. V. sol. KOHAq. Converted into benzanilide by heating with dry PbO or with alcoholic potash at 150°. Yields benzenyl-*o*-amido-phenyl-mercaptan on dry distillation, on heating with S, and also on treatment in alkaline solution with K_3FeCy_6 (Jacobsen, *B.* 19, 1068). Hydroxylamine yields C_6H_5.C(NOH).NHPh.

o-Toluide $C_6H_5.CS.NHC_6H_4Me$[1:2]. [86°]. Formed by melting $BzNHC_6H_4Me$ with P_2S_5 (Stieglitz, *B.* 22, 3160). Yellow, six-sided prisms (from benzene). Hydroxylamine in alcohol forms, on heating, $C_6H_5.C(NOH).NHC_7H_7$ [147°], crystallising in needles.

p-Toluide. [129°]. Formed in like manner (Müller, *B.* 22, 2405), and also by the action of H_2S on $C_6H_5.CCl:NC_7H_7$ (Leo, *B.* 10, 2134; Pfitzinger a. Gattermann, *B.* 22, 1065), and by heating *p*-tolyl-benzamidine with CS_2 (Bernthsen a. Trompetter, *B.* 11, 1759). Long yellow needles, insol. water, v. sol. alcohol, ether, and NaOHAq.

Xylide $C_6H_5.CS.NHC_6H_3Me_2$. [90°]. Formed by heating the benzoyl derivative of (4,2,1)-xylidine with P_2S_5 (Gudeman, *B.* 21, 2552). Small needles (from alcohol). Oxidised by K_3FeCy_6 to oily  $C_6H_2Me_2{<}\genfrac{}{}{0pt}{}{N}{S}{>}CPh$.

Di-phenyl-amide $C_6H_5.CS.NPh_2$. [151°]. Triclinic crystals (Bernthsen, *A.* 192, 37).

(α) *Naphthalide v.* vol. iii. p. 474.

Di-thio-benzoic Acid C_6H_5.CS.SH. Formed by adding an alcoholic solution of K_2S to $C_6H_5.CCl_3$ (Engelhardt a. Latschinoff, *Z.* [2] 4, 455; Klinger, *B.* 15, 862). Heavy, red oil, v. sol. alcohol and ether. Its dilute ethereal solution is crimson. Resinifies when exposed to air.—PbA'_2. Thin orange-red needles (from alcohol or xylene).—HgA'_2. Golden plates (from alcohol).—AgA'. Brown pp., insol. water and benzene.

References. — OXY-THIO-BENZOIC ACID and AMIDO-THIO-BENZAMIDE.

(α)-THIO-BENZOIC ALDEHYDE C_6H_5.CHS. *Benzylidene sulphide.* Formed by passing H_2S into an alcoholic solution of benzoic aldehyde (Laurent, *A. Ch.* [3] 1, 292; Klinger, *B.* 9, 1895; 15, 863; Böttinger, *B.* 12, 1056), or of hydrobenzamide (Cahours, *C. R.* 25, 457). White amorphous powder, softening at 85°, decomposed at a higher temperature. Insol. water and cold alcohol, v. e. sol. benzene and chloroform. Does not combine with $KHSO_3$ or HCy. Potash-fusion yields benzyl mercaptan. On heating with copper it forms CuS and *s*-di-phenyl-ethylene. Alcoholic KSH on heating forms Ph.CS.SK and di-benzyl disulphide. Thiogly-

sollic acid forms $C_6H_4.CH(S.CH_2.CO_2H)_2$ [124°] (Bongartz, *B.* 21, 479).

(β)-Thio-benzoic aldehyde $(C_6H_5.CHS)_x$. [225°]. Formed from the (α)-isomeride by treatment with AcCl, EtI, or a little iodine in benzene (Klinger, *B.* 10, 1877). Prepared by passing H_2S into a mixture of benzoic aldehyde and alcoholic HCl (Baumann a. Fromm, *B.* 22, 2604). Needles. Crystallises from benzene as $(C_7H_6S)_3C_6H_6$, and gives off its benzene at 130°-140°. V. sol. hot HOAc, m. sol. alcohol. On heating with copper-powder it yields CuS and di-phenyl-ethylene. An oily compound $(C_7H_6S)_2H_2S$ is formed, together with benzyl di-sulphide and di-thio-benzoic acid, by the action of alcoholic KSH on benzylidene chloride (Klinger, *B.* 15, 864). This compound yields benzoic acid on treatment with dilute HNO_3.

(γ)-Thio-benzoic aldehyde C_6H_5CHS. [167°]. Occurs in the benzene mother-liquor in the preparation of the (β)-isomeride (B. a. F.). Small pointed needles, much more sol. benzene and chloroform than the (β)-modification, sl. sol. alcohol and ether. Its crystals do not contain benzene of crystallisation. By adding iodine to its solution in benzene it is changed to the (β)-isomeride.

Thio-benzoic orthaldehyde $C_6H_5.CH(SH)_2$.

Methyl ether $C_6H_5CH(SMe)_2$. Formed by passing HCl into a mixture of benzoic aldehyde and MeSH (Bongartz, *B.* 21, 487). Oil. Oxidised by $KMnO_4$ to $C_6H_5.CH(SO_2CH_3)_2$ [163°].

Ethyl ether $C_6H_5.CH(SEt)_2$. Oil (Baumann, *B.* 18, 885).

p-Bromophenyl ether $C_6H_5.CH(SC_6H_4Br)_2$. [80°]. Silky needles (Baumann, *B.* 18, 885).

Reference.—Nitro-thio-benzoic aldehyde.

THIO-BENZOPHENONE $C_6H_5.CS.C_6H_5$. Formed by heating $CSCl_2$ (5g.) with benzene (25 g.) and $AlCl_3$ (9 g.) (Bergreen, *B.* 21, 337). Reddish-brown oil, v. sol. ether, benzene, and hot alcohol. Decomposed by distillation. Reacts with hydroxylamine, forming $Ph_2C:NOH$ and with phenyl-hydrazine, with production of $CPh_2:N_2HPh$.

Thio-benzophenone $(CSPh_2)_x$. [146·5°]. Formed from CCl_2Ph_2 and K_2S (Engler, *B.* 11, 922). Small white needles. Converted by CrO_3 and HOAc into benzophenone. Does not react with hydroxylamine or phenyl-hydrazine.

THIO-BENZOYL-(α)-NAPHTHYLAMINE *v.* vol. iii. p. 474.

THIOBENZPINACONE $C_{26}H_{22}S_2$ *i.e.* $CPh_2(SH).CPh_2(SH)$ or $CPh_2H.S.S.CPh_2H$. [151°]. Formed from benzophenone by the action of alcoholic ammonium sulphide (Engler, *B.* 11, 922) or P_2S_5 (Japp a. Roschen, *C. J.* 49, 479), and, together with thiobenzophenone, by the action of KSH on $C_6H_5.CCl_2.C_6H_5$ (Behr, *B.* 5, 970). Formed also by the action of alcoholic KSH on $(C_6H_5)_2CHCl$, and of P_2S_5 on di-phenyl-carbinol. Slender needles (from alcohol), v. sol. CS_2. In alcoholic solution it is converted by finely-divided copper into tetra-phenyl-ethane $CHPh_2.CHPh_2$.

THIO-BIURET $C_2H_5N_3OS$. Formed by boiling carbimido-urea ('amidodicyanic acid') with ammonium sulphide (Wunderlich, *B.* 19, 452). Needles (containing aq). Sol. hot water and alkalis, v. sl. sol. ether. Gives a white pp with copper salts. By ammoniacal $AgNO_3$ it is converted back into carbimido-urea.

THIO-BUTYRIC ACID C_4H_8SO *i.e.* $CH_3.CH_2.CH_2.CO.SH$. (130°). Formed by distilling butyric acid with P_2S_5 (Ulrich, *A.* 109, 280). Liquid with disgusting smell, v. sl. sol. water, v. sol. alcohol.—PbA'_2. Small crystals (from hot water).

Thio-isobutyric acid. *Methyl ether* $C_5H_{10}SO$ *i.e.* Pr.CO.SMe. (c. 142°). V.D. 57·5. Formed from $Pb(SMe)_2$ and isobutyryl chloride (Obermeyer, *B.* 20, 2922). Oil.

THIO-ISOBUTYRIC ALDEHYDE PrCHS. (70°-90°). A product of the action of S on isobutyric aldehyde at 180° (Barbaglia, *G.* 18, 85). Oil.

(α)-THIO-CARBAMIC ACID $NH_2.CO.SH$. This acid, set free by adding acids to a solution of its ammonium salt, splits up at once into COS and ammonia. The ammonium salt $NH_2.CO.SNH_4$ is prepared by passing gaseous COS into alcoholic NH_3 (Berthelot, *J.* 1868, 160) or into NH_3Aq at 0° (Schmidt, *B.* 10, 191; Kretzschmar, *J. pr.* [2] 7, 474). It forms colourless crystals, v. e. sol. water, m. sol. alcohol, insol. ether. The dry salt becomes yellow in air, forming ammonium sulphocyanide. The dry salt forms thio-urea when heated in a sealed tube at 135°. Thio-urea is also formed when $Pb(OH)_2$ is added to its cold aqueous solution. HgO forms, in the cold, ammonium cyanate (Fleischer, *B.* 9, 438). Water at 100° forms NH_4SH and $(NH_4)HCO_3$. $FeCl_3$ gives a red liquid, and finally a red pp. (Mulder, *A.* 168, 228).

Methyl ether $NH_2.CO.SMe$. [c 98°]. Formed, together with a small quantity of the (β)-isomeride, by adding HCl to a solution of potassium sulphocyanide in boiling MeOH (Blankenhorn, *J. pr.* [2] 16, 375). Monoclinic prisms (from ether). Decomposed by alcoholic NH_3 into MeSH and urea. Aniline at 100° forms MeSH, *s*-di-phenyl-urea and NH_3.

Ethyl ether $NH_2.CO.SEt$. [102°] (Pinner, *B.* 14, 1083); [108°] (F.). Formed in like manner (B.) and also by passing NH_3 into Cl.CO.SEt (Salomon, *J. pr.* [2] 7, 256) and by the action of EtBr on $NH_2.CO.SNH_4$ (Fleischer, *B.* 9, 991). Plates, v. sol. hot water, alcohol, and ether. Decomposed at 150° into mercaptan and cyanuric acid. P_2O_5 converts it into ethyl sulphocyanide.

Isoamyl ether $CO(NH_2).SC_5H_{11}$. [107°]. From $CO(SC_5H_{11})Cl$ and NH_3 (Schöne, *J. pr.* [2] 32, 247). Glittering plates (from ether). Sol. hot water, but decomposed by boiling water. Gives amorphous pps., insol. water, alcohol, and ether with $AgNO_3$, $HgCl_2$ and $PtCl_4$.

Reactions.—Alcoholic NH_3 forms urea and amyl mercaptan.—2. Alcoholic KOH forms K_2CO_3, NH_3 and amyl mercaptan.—3. Heated with aniline it forms NH_3, HSC_5H_{11}, and di-phenyl-urea.

(β)-Thio-carbamic acid $NH_2.CS.OH$.

Methyl ether $NH_2.CS.OMe$. [43°]. Formed by the action of alcoholic NH_3 on MeO.CS.SMe or on MeO.CS.SEt (Salomon, *J. pr.* [2] 8, 115).

Ethyl ether $NH_2.CS.OEt$. *Xanthogenamide.* [38°]. Formed by the action of NH_3 on xanthogenic ether EtS.CS.OEt, on MeS.CS.OEt, and on $(EtO.CS)_2S_2$ (Debus, *A.* 72, 1; 75, 121; 82, 253;

Chancel, *J.* 1851, 513; Salomon a. Maintz, *J. pr.* [2] 8, 114). Monoclinic prisms, sl. sol. water, miscible with alcohol and ether. Decomposed on distillation into mercaptan and cyanic acid. Boiling KOHAq resolves it into alcohol and potassium sulphocyanide. P_2O_5 forms ethyl sulphocyanide (Conrad, *J. pr.* [2] 10, 34). Nitrous acid passed into water containing xanthogenamide in solution forms crystalline $C_6H_{10}N_4SO_2$. $CuSO_4$ followed by HClAq ppts. $C_3H_7NOSCuCl$ as a white crystalline powder, nearly insol. water, sol. hot alcohol. Compounds of CuCl with 2, 3, and 4 mols. of xanthogenamide may be obtained. KI added to a boiling alcoholic solution of $(C_3H_7NOS)_3CuCl$ forms crystals of $(C_3H_7NOS)_2CuI$ and $(C_3H_7NOS)_3CuI$. Compounds $(C_3H_7NOS)_2 3CuSCy$ and $C_3H_7NOSCuSCy$ may also be prepared (Debus). Isovaleric aldehyde in presence of HCl and alcohol forms $C_4H_9.CH(NH.CS.OEt)_2$ [108°] (Bischoff, *B.* 7, 1083). *β*-Iodo-propionic acid forms $NH_2.CO.S.CH_2.CH_2.CO_2H$ [147·5°], which yields CaA'_2 3aq, BaA'_2 2aq, and Ag_2A'' (Langlet, *B.* 24, 3849). *β*-Iodopropionic acid and Ac_2O yield sinapano propionic acid  $CO\left\langle\begin{matrix}S \text{---} CH_2\\NH.CO\end{matrix}\right\rangle CH_2$ [159°], v. sol. hot water, converted by HgO into the mercaptide of *β*-thiolactic acid.

Isobutyl ether $NH_2.CS.OCH_2Pr$. [36°]. Tables (from alcohol or ether) (Mylius, *B.* 5, 976; Blankenhorn, *J. pr.* [2] 16, 380).

Isoamyl ether $NH_2.CS.OC_5H_{11}$. Oil (Johnson, *C. J.* 5. 242).

Di-thio-carbamic acid $NH_2.CS.SH$. Mol. w. 93. The ammonium salt $NH_2.CS.SNH_4$ is formed by passing NH_3 (from 150 pts. NH_4Cl) into 95 p.c. alcohol (600 pts.) containing CS_2 (96 pts.) (Mulder a. Bettink, *J. pr.* 103, 178; *cf.* Zeise, *A.* 48, 95; Debus, *A.* 73, 26). It is also formed by heating $(NH_4)_2CS_3$. On gradually adding HClAq to a cooled conc. solution of the ammonium salt the free acid separates as colourless needles, v. sol. water, alcohol, and ether; acid in reaction. An alcoholic solution of the acid gradually decomposes into CS_2 and the NH_4 salt. An aqueous solution of the acid decomposes on heating into H_2S and HCyS. The di-thio-carbamates also split at 100° into H_2S and sulphocyanides. An alcoholic solution of iodine decomposes $NH_2.CS.SNH_4$, forming EtNCS and $EtNH_2$ (Hofmann, *Z.* [2] 5, 671). Ammonic di-thio-carbamate treated with HCl and solution of I gives crystals of the bisulphide $S_2(CS.NH_2)_2$ (Klason, *J. pr.* [2] 36, 62). $FeCl_3$ added to a solution of the NH_4 salt gives a black pp. turned white by excess. $AgNO_3$ gives a yellow pp., turning black. A solution of aldehyde forms carbothialdine $NH_2.CS.SN(C_2H_4)_2$. Benzoic aldehyde, isovaleric aldehyde, and acroleïn form analogous bodies.

Salts.—NH_4A'. Deliquescent lemon-yellow prisms. On heating with KOHAq it forms K_2S, KSCy, and NH_3.—CuA'_2. Yellow powder, insol. water.—PbA'_2. White pp., blackening on boiling with water.—ZnA'_2: white pp.

Ethyl ether $NH_2.CS.SEt$. Mol. w. 121. [42°]. Formed by passing H_2S under pressure into ethyl sulphocyanide at 100° (Jeanjean, *J.* 1866, 501; Salomon a. Conrad, *J. pr.* [2] 10, 29). Trimetric crystals (from ether), insol. water, v. e. sol. alcohol. Alcoholic NH_3 or KOHAq in the cold forms mercaptan and ammonium sulphocyanide.

Isopropyl ether $NH_2.CS.SPr$. [97°]. Trimetric plates (Gerlich, *A.* 178, 82).

Acetyl derivative of the ethyl ether NHAc.CS.SEt. [123°]. Formed by heating thio-acetic acid with ethyl sulphocyanide (Chanlaroff, *B.* 15, 1987). Yellow needles (from alcohol), v. sol. hot water. Decomposed by distillation into thio-acetic acid and ethyl sulphocyanide. Boiling baryta-water forms mercaptan and acetic acid. Hot dilute HClAq forms $NH_2.CS.SEt$.

Isothiocarbamic ether *v.* DI-ETHYL-(*a*)-THIO-CARBONATE. *Amide.*

THIO-CARBAMIDE *v.* THIO-UREA.

THIOCARBAMYL SULPHIDE $C_2H_4N_2S_3$ *i.e.* $(NH_2.CS)_2S$ (?) Very unstable oil, got by adding HCl to its ammonium salt. Quickly decomposes into CS_2, sulphur, H_2S, and ammonium sulphocyanide. The **ammonium salt** $C_2H_2(NH_4)_2N_2S_3$ is a product of the action of CS_2 on alcoholic NH_3 in the cold (Zeise, *B. J.* 4, 98; Hlasiwetz a. Kachler, *A.* 166, 137). It forms colourless prisms, v. sol. water, m. sol. alcohol, sl. sol. ether. The moist salt slowly decomposes into H_2S and ammonium sulphocyanide. The **cupric salt** $CuC_2H_2N_2S_3$ is canary-yellow.

Thiocarbamyl disulphide $C_2H_4N_2S_3$ *i.e.* $(NH_2.CS)_2S_2$. Formed by the action of Cl on a solution of the ammonium salt of the preceding body, and on ammonium di-thio-carbamate (Debus, *A.* 73, 27). Pearly plates, v. sol. hot alcohol, insol. water. Decomposed by boiling water into CS_2, ammonium sulphocyanide, and S.

THIOCARBIMIDES. *Mustard oils.* Compounds RN:CS. Essential oil of mustard is allyl thiocarbimide. They are formed by the action of $CSCl_2$ on primary amines (Rathke, *A.* 167, 218), and by the action of aqueous $HgCl_2$ on the dithiocarbamates $RNH.CS.SNH_3R$ obtained by heating primary amines with CS_2 and alcohol or ether (Hofmann, *B.* 1, 171; 2, 452; 7, 811; 8, 106; Rudneff, *J. R.* 10, 188). Methyl sulphocyanide is partially converted into methyl thiocarbimide by heating at 180°. Allyl sulphocyanide changes to the mustard oil on boiling. Thiocarbimides are also got by distilling alkyl cyanates with P_2S_5 (Michael a. Palmer, *Am.* 6, 258). The thiocarbimides are pungent oils. They are reduced by Zn and HClAq to amines and CH_2S, whereas sulphocyanides yield HCy, mercaptans, and other products. Amines convert thiocarbimides into thio-ureas; thus aniline combines with phenyl thiocarbimide, forming *s*-di-phenyl-thio-urea. Alcoholic potash, or alcohol at 100° forms thio-carbamic ethers NHR.CS.OEt (Hofmann, *B.* 2, 117; Schiff, *B.* 9, 1316). Water at 200°, or HClAq at 100°, forms amine, CO_2, and H_2S, while with sulphocyanides it yields Et_2S, CO_2, and NH_3. Conc. H_2SO_4 forms amine and COS. HNO_3 forms amine and CO_2; whereas with the isomeric sulphocyanides it forms a sulphonic acid. Hydroxylamine unites with thiocarbimides, forming oxy-thio-ureas NHR.CO.NH.OH (Tiemann, *B.* 22, 1939). Chlorine unites with PhN:CS, forming unstable $(PhNCS)_2Cl_2$, whence boiling water forms $(PhNCS)_2O$ [118°], crystallising in yellow needles (Helmers, *B.* 20, 786).

THIOCARBIMIDO-ACETIC ACID $C_3H_3NSO_2$ *i.e.* $CH_2(N:CS).CO_2H$. Formed by boiling thiohydantoïn with HClAq (Volhard, *J. pr.* [2] 9, 6), and by boiling isoamyl sulphocyano-acetate with fuming HClAq (Claësson, *B.* 10, 1352; Heintz, *A.* 136, 232). Trimetric plates, v. e. sol. hot water. Oxidised by HNO_3 to H_2SO_4 and oxalic acid. Weak acid.—BaA'_2 aq. Four-sided prisms, sl. sol. cold water. Benzoic aldehyde and NaOHAq (1 mol.) react, forming the compound $CHPh:C(CO_2Na).S.CO.NH_2$, which crystallises with $1\frac{1}{2}$aq and is converted by HCl into $\begin{smallmatrix}CO.S\\NH.CO\end{smallmatrix}>C:CHPh$ [242°] (Andreasch, *M.* 10, 73).

THIOCARBIMIDO-BENZOIC ACID *v.* *m*-AMIDO-BENZOIC ACID.

THIOCARBONIC ACID.

Thiocarbonates *v.* vol. i. p. 703. The thiocarbonic ethers that have not been treated of in former articles are described below.

Methyl thiocarbonates *v.* vol. iii. p. 399.

Methyl iso-dithiocarbonate $CO(SMe)_2$. (169°). Formed by warming methyl sulphocyanide with H_2SO_4 (Schmitt a. Glutz, *B.* 1, 166).

Ethyl thiocarbonates *v.* vol. ii. p. 520.

Ethylene thiocarbonates *v.* vol. ii. p. 493.

Ethylene di-ethyl di-thio-di-carbonate $C_2H_4(S.CO_2Et)_2$. Formed by heating $C_2H_4Br_2$ with $KS.CO_2Et$ in alcohol (Welde, *J. pr.* [2] 15, 52). Thick oil, converted by alcoholic potash into $C_2H_4(SH)_2$ and $KO.CO_2Et$.

Isobutyl di-thio-carbonic acid $CH_2Pr.O.CS_2H$.

Salts.—NaA'. Formed from C_4H_9ONa and CS_2. Yellowish white needles, v. e. sol. water and alcohol.—KA'. Needles (from alcohol). S.G. $\frac{15}{}$ 1·371 (Clarke, *B.* 11, 1505). Chlorine gas passed into its aqueous solution forms oily $(CH_2PrO.CS)_2S_2$ (Mylius, *B.* 5, 976).

Ethyl ether EtA'. (228°).

Isobutyl ether $CH_2Pr.O.CS.SCH_2Pr$. (249°). S.G. $\frac{12}{}$ 1·009 (Mylius, *B.* 5, 975).

Isoamyl ether $CH_2Pr.O.CS.SC_5H_{11}$. (265°–270°) (Mylius).

Isoamyl di-thio-carbonic acid $C_5H_{11}.O.CS.SH$. Oil, with unpleasant smell.

Salts.—KA'. Formed from fusel oil, KOH, and CS_2 (Balard, *A. Ch.* [3] 12, 307; Erdmann, *J. pr.* 31, 4; Desains, *A. Ch.* [3] 20, 505; Johnson, *C. J.* 5, 142). Gives a lemon-yellow pp. with $CuSO_4$.—PbA'_2. Plates. Iodine forms oily $(C_5H_{11}O.CS)_2S_2$.

Di-isoamyl *s*-di-thio-carbonate $CO(SC_5H_{11})_2$. (281°) (Schmitt a. Glutz).

Cetyl di-thiocarbonate *v.* vol. i. p. 728.

Iso-butyl-tri-thio-carbonic acid $C_4H_9S.CS_2H$. Formed from C_4H_9SNa and CS_2 (Mylius, *B.* 6, 316). The Na salt crystallises in yellow needles, v. sol. alcohol and ether.

Isobutyl ether $(C_4H_9S)_2CS$. (287°). Got by heating aqueous K_2CS_3 with isobutyl iodide. Yellow oil with faint odour.

Di-isoamyl-tri-thiocarbonate $(C_5H_{11}S)_2CS$. (247°). S.G. ·88 (Husemann, *A.* 126, 297). Oil, with unpleasant smell.

Di-allyl tri-thio-carbonate $(C_3H_5S)_2CS$. (170°–175°). S.G. ·94. Formed from allyl iodide and Na_2CS_3 in the cold (Husemann, *A.* 126, 269). Pungent yellow oil, with offensive odour.

THIOCARBONYL - ACETOACETIC ETHER $CS:CAc.CO_2Et$. [156°–162°]. Formed from thiocarbonyl chloride and acetoacetic ether (Bergreen, *B.* 21, 347). Yellow needles, sl. sol. ether and ligroïn.

THIO-CARBONYL-DI-AMIDO-DI-BENZOIC ACID *v.* *m*-AMIDO-BENZOIC ACID.

THIOCARBONYL - BENZOYL - ACETIC ETHER $CS:CBz.CO_2Et$. [164°]. Formed from $CSCl_2$ and benzoylacetic ether (Bergreen, *B.* 21, 351). Yellow needles, sol. alcohol-chloroform.

THIO-CARBONYL CHLORIDE *v.* *Sulphochloride* of CARBON.

Thio-carbonyl tetrachloride *v.* PER-CHLORO-METHYL-MERCAPTAN.

THIO - CARBONYL - ETHYL - *o* - AMIDO-PHENOL $C_6H_4<\begin{smallmatrix}NEt\\O\end{smallmatrix}>CS$. [112°]. (above 300°). Formed from ethyl-*o*-amido-phenol and $CSCl_2$ (Seidel, *J. pr.* [2] 42, 449, 457). Insol. water and dilute NaOHAq, m. sol. cold alcohol. HClAq at 170° forms ethyl-amido-phenol, CO_2, and H_2S. PCl_5 yields $C_6H_4<\begin{smallmatrix}N\\O\end{smallmatrix}\gg CCl$.

THIO - CARBONYL - METHYL - AMIDO-PHENOL $C_6H_4<\begin{smallmatrix}NMe\\O\end{smallmatrix}>CS$. [128°]. (above 300°). Formed by the action of $CSCl_2$ on methyl-*o*-amido-phenol (Seidel, *J. pr.* [2] 42, 452). Needles, insol. water, sl. sol. cold alcohol.

THIO - CARBONYL - DI - (β) - NAPHTHYL - THIO - UREA $C_{10}H_7.N<\begin{smallmatrix}CS\text{———}\\C(NC_{10}H_7)\end{smallmatrix}>S$. [152°]. Formed from di-(β)-naphthyl-thio-urea and $CSCl_2$ in benzene (Freund a. Wolf, *B.* 25, 1466). Stellate groups of needles, m. sol. hot benzene. Melts at 152° with evolution of gas, forming a solid melting at 224°.

THIO-CARBONYL-DI-*p*-TOLYL-THIO-UREA $C_7H_7.N:C<\begin{smallmatrix}N(C_7H_7)\\S\text{———}\end{smallmatrix}>CS$. [109°]. Formed from di-*p*-tolyl-thio-urea [172°] and $CSCl_2$ in ether (Freund a. Wolf, *B.* 25, 1465). Yellowish needles, v. sol. hot alcohol and ether. Converted by HgO into carbonyl-di-tolyl-thio-urea [112°].

THIOCHRONIC ACID $C_6H_6S_5O_{17}$ *i.e.* $C_6(OH)(SO_4H)(SO_3H)_4$. Formed by adding tetrachloro-quinone to a conc. solution of K_2SO_3 (Hesse, *A.* 114, 313; Graebe, *A.* 146, 40). Yellow trimetric prisms, v. sol. hot water, insol. alcohol. Coloured brownish-red by $FeCl_3$. Reduces $AgNO_3$. Converted into hydroquinone disulphonic acid by heating with water at 135°, or by boiling with HClAq.

Euthiochronic acid $C_6H_4S_2O_{10}$ *i.e.* $C_6(OH)_2O_2(SO_3H)_2$. *Di-oxy-quinone disulphonic acid.* Formed by boiling thiochronic acid with KOHAq. Deliquescent yellow needles, v. sol. water and alcohol. Reduced by tin and HClAq to $C_6H_6S_2O_{10}$, which yields Na_2A''2aq and K_2A''2aq, which are re-oxidised in aqueous solution by air to euthiochronates.—Na_4A^{iv}aq (dried at 150°).—K_4A^{iv}2aq. Minute lemon-yellow prisms, v. sol. water.—K_3HA^{iv}aq. Small orange-red four-sided prisms.—Ba_2A^{iv}4aq. Ochre-yellow pp.—Ag_4A^{iv}: amorphous pp.

(α) - **THIO - CINNAMIC ACID** C_9H_8SO *i.e.* $C_6H_5CH:CH.CO.SH$. Formed from cinnamoyl chloride and $Pb(SEt)_2$, the resulting oily ether being boiled with alcoholic KSH (Engelhardt, *Z.* [2] 4, 359).—KA′. Crystalline.

(β)-Thio-cinnamic acid. *Amide* $C_9H_7S.NH_2$. [112°]. Formed by passing H_2S into a solution of cinnamic nitrile in alcoholic NH_3 (Rossum, *Z.* 1866, 362; Krüss, *B.* 17, 1768). Golden plates.

(α)-**THIO-CINNAMIC ALDEHYDE** $(C_9H_8S)_3$. [167°]. Formed by passing H_2S into oil of cinnamon dissolved in alcoholic HCl (Baumann a Fromm, *B.* 24, 1452). Crystalline, v. e. sol. benzene, sl. sol. alcohol.

(β)-Thio-cinnamic aldehyde $(C_9H_8S)_3$. [213°]. Formed at the same time as the (α)-isomeride. Prisms, v. sl. sol. cold benzene and alcohol.

Thio-cinnamic orthaldehyde. *Phenyl ether* $C_6H_5CH:CH.CH(SPh)_2$. [81°]. Formed by passing dry HCl into a mixture of cinnamic aldehyde and phenyl mercaptan (Baumann, *B.* 18, 885). Needles (from ligroïn).

p-Bromo-phenyl ether $CHPh:CH.CH(S.C_6H_4Br)_2$. [107°]. Needles (from alcohol or ether).

Glycollyl ether $CHPh:CH.CH(S.CH_2.CO_2H)_2$. [143°]. Formed from cinnamic aldehyde and thioglycollic acid (Bongartz, *B.* 21, 481). Plates (from water). Zinc-dust in alkaline solution converts it into $CHPh:CH.CH_2.S.CH_2.CO_2H$ [77°], crystallising from dilute alcohol in plates.

TRI-THIO-CITRIC ETHER $C_3H_5O(CO.SEt)_3$. Formed from tri-phenyl citrate and NaSEt in presence of ether (Seiffert, *J. pr.* [2] 31, 470). Oil, smelling like mercaptan.

THIO-COUMARIN  $C_6H_4\begin{cases}CH:CH\\ \quad\;\; | \\ O\;\;.CS\end{cases}$. [101°].

Formed by heating equal parts of coumarin and P_2S_5 at 120°; the yield is 50 p.c. Also by heating *o*-coumaric acid with P_2S_5. Long yellow needles, v. sol. alcohol, ether, and benzene; insol. water. Sublimable. By heating with aqueous alcoholic KOH it is reconverted into coumarin. Unlike coumarin it readily reacts with hydroxylamine and with phenyl-hydrazine (Tiemann, *B.* 19, 1661).

THIO-CRESOL *v.* Tolyl mercaptan.

THIO-CROCONIC ACID $C_5H_2O_4S$, probably  $SC\begin{cases}C(OH).CO\\ C(OH).CO\end{cases}$. Formed by saturating a warm solution of potassium croconate treated with 2 mols. of HCl, with H_2S.—BaA″ 2aq: brownish-yellow amorphous pp., v. sol. dilute HCl, which after some time changes to reddish-brown crystals with violet reflex, insol. dilute HCl (Nietzki a. Benkiser, *B.* 19, 299).

THIO-CUMINIC ACID. *Amide* $C_{10}H_{13}NS$ *i.e.* $C_3H_7.C_6H_4.CS.NH_2$. Formed by passing H_2S into a solution of cuminic nitrile in alcoholic NH_3 (Czumpelik, *B.* 2, 185). Needles, v. sol. hot alcohol. Converted in alcoholic solution by iodine into $C_{20}H_{22}N_2S$ [45°] crystallising in prisms (Wanstrat, *B.* 6, 322).

THIODICYANDIAMIDINE *v.* Guanyl thiourea.

THIOCYANIC ACID *v.* Sulphocyanic acid.

THIOCYANO- *v.* Sulphocyano-.

DI-THIO-CYANURIC ACID $Cy_3(SH)_2(OH)aq$.

Preparation.—An alcoholic solution of KCyS is mixed with the calculated quantity of HCl, filtered from KCl, and evaporated at 40°. The residue is extracted with strong NH_3Aq and $BaCl_2$ is added to the filtrate. The barium salt gradually separates in globular crystals (Klason, *J. pr.* [2] 33, 121). Yield, very small.

Properties.—White scales (from hot water). Sol. NaOHAq. A solution of the potassium salt gives pps. with $AgNO_3$, $HgCl_2$, and $Pb(OAc)_2$.

Reactions.—1. Conc. HCl at 130° gives cyanuric acid and H_2S.—2. Cold $KMnO_4Aq$ and hot HNO_3Aq form cyanuric acid.—3. *Iodine* forms $(HOCy_3)_2S_4$ as a white crystalline powder.

Salts.—KH_2A'''. Silvery mass of microscopic prisms.—$BaHA'''2aq$.

Tri-thio-cyanuric acid $Cy_3(SH)_3$. Formed by warming powdered $C_3N_3Cl_3$ (1 mol.) with conc. aqueous KSH (4 mols.) (Hofmann, *B.* 18, 2196; Klason, *J. pr.* [2] 33, 116). Minute prisms, when ppd. from dilute solutions; amorphous, from conc. solutions. Nearly insol. hot water, alcohol and ether. Not decomposed at 200°. $FeCl_3$ gives no colour in solutions of the acid, but in conc. solutions of the K salt it gives a white pp. and a yellow solution.

Reactions.—1. HClAq at 130° gives cyanuric acid and H_2S.—2. Alkaline $KMnO_4$ at 20° gives cyanuric acid.—3. Warm HNO_3 forms cyanuric acid.—4. At 360° it gives off CS_2 and some HCyS and leaves melem $C_6H_6N_{10}$.

Salts.—$K_3A'''3aq$.—$K_3H_3A'''_4 6aq$.—NaH_2A'''. Crystals, v. sol. water.—$BaHA'''3aq$. Yellow crystals, ppd. by addition of $BaCl_2$ and NH_3Aq.—$BaH_4A'''_2 2aq$. Prisms, m. sol. water.—$SrHA'''5aq$.—$CaHA'''5aq$. Prisms, m. sol. water.

Methyl ether Me_3A'''. [189°]. Got by heating methyl sulphocyanide with a few drops of HClAq at 100° (Hofmann, *B.* 13, 1351; 18, 2197, 2755, 2774; 19, 2065). Hexagonal crystals. An alcoholic solution of ethylamine at 100° forms $Cy_3(NHEt)(SMe)_2$ [114°] while at 140° it yields $Cy_3(NHEt)_2SMe$ [84°]. Alcoholic NH_3 forms, in like manner, $Cy_3(NH_2)(SMe)_2$ and $Cy_3(NH_2)_2SMe$.

Ethyl ether Et_3A'''. [27°]. (350°). Formed from Cy_3Cl_3 and NaSEt. Colourless tablets (from HOAc) converted by alcoholic NH_3 at 180° into $Cy_3(NH_2)(SEt)_2$ [112°] (crystallising in trimetric forms; $a:b:c = \cdot669:1:\cdot391$, v. sol. ether), accompanied by $Cy_3(NH_2)_2(SEt)$ [165°], which is insol. ether (Klason, *J. pr.* [2] 33, 298).

Amyl ether $(C_5H_{11})_3A'''$. Oil. Yields $Cy_3(NH_2)(SC_5H_{11})_2$ [82°] and $Cy_3(NH_2)_2SC_5H_{11}$ [178°].

Phenyl ether Ph_3A'''. [97°]. Prisms (from HOAc).

p-Tolyl ether $(C_7H_7)_3A'''$. [114°].

THIO-DI-ETHYL-ANILINE *v.* Tetra-ethyl-di-amido-di-phenyl sulphide.

THIO-ETHYL-COUMARIN $C_6H_4\begin{cases}CH:CEt\\ O—CS\end{cases}$. [94°]. Formed by heating (α)-ethyl-coumarin with P_2S_5 at 120° (Aldringen, *B.* 24, 3462). Yellowish-red plates, sol. alcohol. May be sublimed.

THIO-ETHYLENE GLYCOL *v.* Ethylene mercaptan.

THIO-FORMIC ACID H.CO.SH (?) [120°]. Formed by the action of H_2S on lead formate (Wöhler, *A.* 91, 125; Limpricht, *A.* 97, 361), but not from P_2S_5 and formic acid (Hurst, *A.* 126, 68). Small transparent crystals (from alcohol) with alliaceous odour, insol. water. May be sublimed. According to Nicol (*Pr. E.* 10, 425) a solution of thioformic acid, got from

PbA'_2 and H_2S, rapidly decomposes, yielding formic acid.

Salts.—H.CO.SK. Formed from $CHCl_3$ and alcoholic K_2S (Nicol, *T. E.* 29, 531). Needles, sol. water and alcohol, nearly insol. dilute alcohol. $AgNO_3$ added to its aqueous solution forms a white pp., turning black on standing. HNO_3 yields S and formic acid. HgO also gives formic acid.—$(H.CO.S)_2Pb$.

Anilide H.CS.NHPh. *Thioformanilide.* [137°]. Formed from dry phenyl carbamine and H_2S (Hofmann, *B.* 10, 1095, 1238). Formed also by passing dry H_2S over di-phenyl-formamidine NPh:CH.NHPh at 150° (Bernthsen, *A.* 192, 35). Prepared by warming formamidine (5 pts.) with P_2S_5 (3 pts.), the yield being 60 p.c. of the theoretical (Hofmann, *B.* 11, 338). Thin plates (from water), partially decomposed on distillation into H_2S and phenyl carbamine. Its solution tastes bitter. Decomposed by hot KOHAq into aniline, H_2S, and formic acid. Heated in a sealed tube at 180° it yields $C_{14}H_{12}N_2S$ [140°] v. sol. alcohol (Nicol, *B.* 15, 211). NaOEt and EtBr yield oily CH(SEt):NPh (c. 235°) (Wallach a. Wüsten, *B.* 16, 145).

o-Toluide $H.CS.NHC_7H_7$ [96°]. Got by heating formyl-toluide with P_2S_5 (Senier, *C. J.* 47, 762).

p-Toluide. Yellow needles.

Xylide $HCS.NHC_6H_3Me_2$. [105°]. Small needles (from alcohol) (Gudeman, *B.* 21, 2549).

Thio-orthoformic acid. *Ethyl ether* $CH(SEt)_3$. Formed by boiling chloroform with aqueous NaSEt (Gabriel, *B.* 10, 186; Claesson, *J. pr.* [2] 15, 174). Oil, with nasty smell, partly decomposed on boiling. Oxidised by HNO_3 to ethane sulphonic acid. Fuming HClAq yields formic acid and mercaptan

Benzyl ether $CH(SC_7H_7)_3$. [98°]. Formed from $NaSC_7H_7$ and chloroform (Dennstedt, *B.* 11, 2265). White crystals.

Phenyl ether $CH(SPh)_3$. [39·5°]. Trimetric tables. Oxidised by potassium permanganate to $PhS.CH(SO_2Ph)_2$ [176°] (Laves, *B.* 23, 1416; 25, 347).

Reference.—CHLOROFORMIC ACID.

THIO-FORMIC ALDEHYDES

Thio-formic paraldehyde $(CH_2S)_3$. *Methylene sulphide.* Mol. w. 138. [216°]. V.D. 5·08 (obs.).

Formation.—1. By heating Na_2S with methylene iodide (Husemann, *A.* 126, 293).—2. By reducing CS_2 with Zn and HClAq (Girard, *A.* 100, 306).—3. By the action of H_2S on formic aldehyde or trioxymethylene.

Preparation.—By saturating a mixture of formic aldehyde (2 vols.) and conc. HClAq (4 vols.) with H_2S (Baumann, *B.* 23, 67).

Properties.—Prisms, smelling like onions. Insol. cold water, sl. sol. alcohol and ether, m. sol. benzene and CS_2. May be sublimed. Oxidised by $KMnO_4$ to a trisulphone and also $C_3H_6S_3O_5$ crystallising in colourless needles.—Forms: $C_3H_6S_3 2AgNO_3$. — $C_3H_6S_3AgNO_3\,\frac{3}{4}aq.$ — $C_3H_6S_3HgCl_2$. — $(C_3H_6S_3)_2 2PtCl_2$. — $(C_3H_6S_3)_2PtCl_4$ (Hofmann, *B.* 2, 152; 3, 584; Girard, *C. R.* 70, 625).

Thio-formic orthaldehyde.

Ethyl ether $CH_2(SEt)_2$. (184°) (C.); (180°) (F.). S.G. ^{22} ·987. Formed from CH_2I_2 and NaSEt (Claesson, *J. pr.* [2] 15, 176). Liquid with unpleasant smell. Oxidised by HNO_3 to ethane sulphonic acid. $KMnO_4$ and H_2SO_4 yield $CH_2(SO_2C_2H_5)_2$ (Fromm, *A.* 253, 155).

Thio-formic metaldehyde $(CH_2S)_n$. [176°]. Formed, as a white amorphous substance, on warming an aqueous or alcoholic solution of hexamethylene-amine saturated with H_2S (Wohl, *B.* 19, 2344). Insol. most solvents. Decomposed when heated above its melting-point.

Di-thio-formic paraldehyde $(C_3H_6S_2O)_2$ aq. *Dithioglyceric aldehyde.* [82°]. (180°–185°). Formed by passing H_2S into a solution obtained by electrolysis of dilute glycerin (Renard, *A. Ch.* [5] 17, 307). Amorphous waxy mass, sol. warm water, insol. alcohol and ether.

(*a*)-**THIO-FURFURALDEHYDE** $(C_5H_4SO)_2$. [128°]. Formed, together with the (*β*)-isomeride, by passing H_2S into a solution of furfuraldehyde (10 g.) in alcohol (100 c.c.) and HClAq (20 c.c.) at −5° (Baumann a. Fromm, *B.* 24, 3593). Crystals, v. e. sol. alcohol and chloroform, insol. water.

(*β*)-**Thio-furfuraldehyde** $(C_5H_4SO)_3$. [229°]. Needles, v. sl. sol. alcohol, v. sol. chloroform.

Thio-furfuraldehyde $(C_4H_5SO)_n$ [$n = 20$ to 24]. Mol. w. (by Raoult's method) 2182. Formed by mixing an alcoholic solution of furfuraldehyde with alcoholic ammonium sulphide (Cahours, *A.* 69, 85; B. a. F.). White crystalline powder, softens at 80° and is melted at 91°. Thiofurfuraldehyde is decomposed by warm aniline, yielding furfuraldehyde and H_2S (Schiff, *B.* 19, 2153).

THIO-GLYCERIN *v.* GLYCERIN.

THIO-GLYCOL *v.* ETHYLENE MERCAPTAN.

THIO-GLYCOLLIC ACID $CH_2(SH).CO_2H$. *Sulphydro-acetic acid.*

Formation.—1. By reducing the compound $ClSO_2.CHCl.COCl$ with tin and HClAq (Siemens, *B.* 6, 659).—2. By adding $CH_2Cl.CO_2H$ (1 mol.) to conc. KSHAq (2 mols.) (Claesson, *A.* 187, 113).—3. By the action of H_2S on glyoxylic acid in presence of Ag_2O (Böttinger, *A.* 198, 215).—4. By boiling thiohydantoïn with baryta-water (Andreasch, *B.* 12, 1385).—5. Together with HSCy, by the decomposition of rhodanic acid $C_3H_3NS_2O$ with baryta-water (Ginsberg a. Bondzynski, *B.* 19, 113).

Properties.—Oil, miscible with water, alcohol, and ether. Decomposes when quickly heated. Very dilute $FeCl_3$ gives a fugitive indigo-blue colour, changed by a few drops of NH_3Aq to dark red and then to violet. Excess of $FeCl_3$ oxidises it to di-sulphido-di-acetic acid $S_2(CH_2.CO_2H)_2$, which is also readily formed by atmospheric oxidation of the alkaline solution. A solution of the K salt added to $CuSO_4$ gives a bluish-black pp. reduced by further addition of the K salt to the white cuprous salt $Cu_2(S.CH_2.CO_2H)_2$. HCl passed through a mixture of thioglycollic acid and acetoacetic ether gives rise to crystalline $CO_2Et.CH_2.CMe(S.CH_2.CO_2H)_2$ [96°] (Bongartz, *B.* 21, 485). Acetyl-propionic acid forms, in like manner, $CO_2H.CH_2.CH_2.CMe(S.CH_2.CO_2H)_2$ [154°]. Aldehydes react, forming the compound $CRH(S.CH_2.CO_2H)_2$, compounds which are produced either on standing, on warming, or on treatment with $ZnCl_2$ or dry HCl (Bongartz, *B.* 19, 1931; 21, 479). Such compounds obtained by using acetic, benzoic, cinnamic, *o*-oxy-benzoic, and *o*-, *m*-, and *p*-nitro-benzoic aldehydes melt at 108°, 124°, 146°, 148°, 123°, 130°, and 162° respectively. Thioglycollic acid reacts with ketones in presence of $ZnCl_2$ or HCl, forming acids $CRR'(S.CH_2.CO_2H)_2$: such compounds obtained from acetone, acetophenone, and benzophenone melt at 135°, 139°, and 164° respectively.

Salts. — KHA″aq (from water). — KHA″ (from alcohol). Decomposes K_2CO_3, forming $CH_2(SK).CO_2K$.—BaA″ 3aq: crystalline pp.— $BaH_2A''_2$: gummy.—CdA″.—$Hg(S.CH_2.CO_2H)_2$. Needles or flat prisms, v. sol. hot water and alcohol.—$Hg_2(S.CH_2.CO_2)_4BaH_2$. Minute crystals.—$Hg_3(S.CH_2.CO_2)_6AlH_3$. — $Hg_2MnH_2A''_4$. — $HgPbA''_2$.—HgA″.—PbA″.—$Bi(HA'')_3$. [c. 33°]. Yellow pp.—$Cu_2H_2A''_2$. White pp.—$Cu_2BaA''_2$.—Ag_2A''.—$Ag_2(NH_4)A''(NO_3)$.—$Ag_2HgA''_2$.

Ethyl ether EtA′. Formed by boiling thioglycollic acid with alcohol and a little H_2SO_4 (Claesson, *A.* 187, 116). Oil with nasty smell. Slowly decomposed by boiling into H_2S and $S(CH_2.CO_2Et)_2$. Alcoholic $HgCl_2$ ppts. $ClHg.S.CH_2.CO_2Et$, converted by excess of the ether into $Hg(S.CH_2.CO_2Et)_2$ (Wislicenus, *A.* 146, 145).

Ethyl derivative $CH_2(SEt).CO_2H$. Formed by mixing $CH_2Cl.CO_2Et$ with NaSEt and alcohol (Claesson, *B.* 8, 120). Liquid, v. sol. alcohol and ether, m. sol. water. Decomposed by heat, but may be distilled with steam. — KA′.—BaA'_2. — CaA'_2.—MgA'_2 3aq. — ZnA'_2 2aq. —CdA'_2 aq. [85°]. – CoA'_2 2aq. [90°].—NiA'_2 2aq. —CuA'_2 2aq. – AgA′aq. Crystalline pp.

Ethyl ether of the ethyl derivative $CH_2(SEt).CO_2Et$. (188°). S.G. ± 1·0169. Oil. Converted by EtI at 120° into crystalline $CH_2(SEt_2I).CO_2Et$.

Ethyl ether of the isoamyl derivative $CH_2(SC_5H_{11}).CO_2Et$. (230°). S.G. ^{4} ·9797. Oil.

Phenyl derivative v. PHENYL-THIO-GLYCOLLIC ACID.

Benzyl derivative $CH_2Ph.S.CH_2.CO_2H$. [59°]. Formed from $CH_2Cl.CO_2H$ and benzyl mercaptan (Gabriel, *B.* 12, 1641). Flat tables. Yields EtA′ (275°–290°) and the amide $CH_2Ph.S.CH_2.CONH_2$ [97°] crystallising in flat plates.

Phenyl-phenyl derivative $C_6H_4Ph.S.CH_2.CO_2H$. [170°]. Crystals.

Amide $CH_2(SH).CO.NH_2$. A product of the passage of H_2S through an alcoholic solution of chloro-acetamide containing a little NH_3 (Schulze, *Z.* 1865, 73). Groups of small prisms.

Ethyl derivative of the amide $CH_2(SEt).CONH_2$. [44°]. Formed from $CH_2(SEt).CO_2Et$ and ammonia. Thin prisms.

Reference.—NITROSO-THIO-GLYCOLLIC ACID.

THIO-GLYCOLLIC ORTHALDEHYDE. *Ethyl derivative of the ether* $CH_2(SEt).CH(OEt)_2$. (169°). Formed from $CH_2Cl.CH(OEt)_2$ and NaSEt (Autenrieth, *B.* 24, 162). Volatile in steam.

Phenyl derivative of the ethyl ether $CH_2(SPh).CH(OEt)_2$. (273°). Got in like manner.

THIO-HYDANTOÏC ACID $C_3H_6N_2SO_2$ *i.e.* $NH_2.CS.NH.CH_2.CO_2H$ or $NH_2.C(NH).S.CH_2.CO_2H$. Formed by heating sodium chloro-acetate in aqueous solution with thio-urea (Maly, *A.* 189, 380). Crystalline powder, sl. sol. water, v. sol. acids and alkalis. Decomposed by heat. Converted into thio-hydantoïn by warming with Na_2CO_3Aq or HClAq.

THIOHYDANTOÏN $C_3H_4N_2SO$ *i.e.*

$$CS\begin{cases}NH.CH_2\\NH.CO\end{cases} \text{ or } C\begin{cases}S\\NH.CH_2\\NH—CO\end{cases}.$$

Formation.—1. By heating thio-urea with chloro-acetic acid or chloro-acetamide (Volhard, *A.* 166, 383; Mulder, *B.* 8, 1264; Maly, *A.* 168, 133; *B.* 10, 1853; Claesson, *B.* 10, 1352).—2. By heating thioglycollic acid (2 mols.) with cyanamide (1 mol.) in aqueous solution (Andreasch, *B.* 13, 1421; *M.* 1, 442).

Preparation.—Thio-urea (50 g.) dissolved in water (500 c.c.) is mixed with chloro-acetic acid (62 g.) in water (50 c.c.), heated to 90°, cooled, and mixed with the calculated quantity of NaOH (Andreasch, *M.* 8, 414).

Properties.—Long needles (from hot water), insol. alcohol and ether. Decomposes about 200°. Since it cannot be desulphurised by HgO, Liebermann (*A.* 207, 132) suggests that it does not contain the group CS.

Reactions.—1. *Chlorine* passed into its cooled solution in HClAq forms thio-oxy-hydantoïn (Kramps, *B.* 13, 788).—2. Br forms di-bromo-thio-hydantoïn. — 3. $KClO_3$ and HCl yield $C_3H_5KN_2SO_5$, crystallising in monoclinic tables, S. 1·7 at 22°; 23·3 at 100°, converted by nitrous acid into $SO_3H.CH_2.CO_2H$, and by baryta-water into sulpho-acetic acid and urea (Andreasch, *B.* 13, 1423; *M.* 4, 131).—4. Baryta-water forms thioglycollic acid and dicyandiamide. — 5. Boiling HClAq forms thiocarbimido-acetic acid.

Salts.—$Ag_2C_3H_2N_2SO$.—$B'_2H_2SO_4$. Plates. —$B'HNO_3$.– B′HCl.– $B'H_2C_2O_4$ aq. Prisms.— $B'_2H_2PtCl_6$.—$B'C_6H_3N_3O_7$. Minute yellow needles.

References.—DI-BROMO- and NITROSO-THIO-HYDANTOÏN.

DI-THIO-HYDROQUINONE $C_6H_4(SH)_2$. [98°]. Formed by reducing benzene *p*-disulphonic chloride with tin and HClAq (Körner a. Monselise, *G.* 6, 142). Formed also from $(C_6H_4(NH_2))_2S_2$ by diazotisation, treatment with potassium xanthate, and saponification of the product with alcoholic potash (Leuckart, *J. pr.* [2] 41, 205). Six-sided plates, slowly oxidised by air.

THIO-ISATYDE *v.* ISATYDE.

THIO-LACTIC ACID $CH_3.CH(SH).CO_2H$. *α-Sulphydro-propionic acid.*

Formation.—1. From α-chloro-propionic acid and KHS (Schacht, *A.* 129, 1; Lovén, *J. pr.* [2] 29, 368).—2. By the action of H_2S on silver α-chloro-propionate or silver pyruvate (Böttinger, *A.* 188, 320; *B.* 9, 404, 804, 1061; 11, 1561; 18, 486).

Preparation.—By saturating a solution of pyruvic acid with H_2S, and adding conc. HClAq and zinc (Lovén).

Properties.—Syrup, miscible with water, alcohol, and ether. May be distilled *in vacuo*. Its odour is unpleasant. $FeCl_3$ gives a transient indigo colour, and then oxidises it to sulphido-dipropionic acid. $CuSO_4$ gives a violet solution; a smaller quantity of $CuSO_4$ ppts. the cuprous salt. Cobalt acetate and air gives a brown colour.

Salts.—BaA'_2 (at 130°). Gummy mass.— $Hg(S.CHMe.CO_2H)_2$. — $Hg(S.CHMe.CO_2K)_2$ 2aq. $Hg(S.CHMe.CO_2)_2Ba$ 2½aq. — $AgS.CHMe.CO_2H$.

—$Bi(S.CHMe.CO_2H)_3$. — $Pt(S.CHMe.CO_2H)_2$. — $CuS.CHMe.CO_2H$. Yellow pp.—$PbC_3H_4O_2S$.

Ethyl ether EtA′. Oil. Yields $CuS.CHMe.CO_2Et$ as a yellowish powder.

THIO-DILACTYLIC ACID *v.* SULPHIDO-DI-PROPIONIC ACID.

THIO-MALIC ACID $C_4H_6SO_4$. Formed from bromo-succinic acid and aqueous KSH at 110° (Carius, *A.* 129, 6). Deliquescent mass, oxidised by dilute HNO_3 to sulpho-succinic acid.—BaA″.—Ag_2A''. Bulky pp., readily blackening.

THIO-MESITOL *v.* TRI-METHYL-PHENYL MERCAPTAN.

THIO-DI-METHYL-ANILINE *v.* TETRA-METHYL-DI-AMIDO-DI-PHENYL SULPHIDE.

THIO-METHYL-COUMARILIC ETHER $C_{12}H_{12}SO_2$ *i.e.* $C_6H_4<\!\begin{matrix}CMe\\O\end{matrix}\!>C.CO.SEt$. [91°]. Formed from methyl-coumarilic ether and P_2S_5 (Hantzsch, *B.* 19, 2400). Yellow needles (from alcohol), v. sol. ether.

THIO-(a)-METHYL-COUMARIN $C_{10}H_8SO$ *i.e.* $C_6H_4<\!\begin{matrix}CH:CMe\\O-CS\end{matrix}$. [122°]. Formed by heating (a)-methyl-coumarin with P_2S_5 at 120° (Aldringen, *B.* 24, 3460). Yellow needles, insol. water, v. sol. alcohol. Converted by alcoholic potash into (a)-methyl-coumarin.

THIO-METHYL-DI-PHENYL-AMINE *v.* METHYL-IMIDO-DI-PHENYL SULPHIDE.

THIO-METHYL-URACIL $C_5H_6N_2SO$ *i.e.*  $CS<\!\begin{matrix}NH.CMe\\NH.CO\end{matrix}\!>CH$ (?). S. ·054 at 21°. Formed by the action of alcoholic potash on the needles which separate after some days from a solution of thio-urea (1 mol.) and acetoacetic ether (1 mol.) in alcohol to which a little HCl has been added (Nencki a. Sieber, *J. pr.* [2] 25, 72; List, *A.* 236, 1; Behrend, *B.* 19, 219). Plates, v. sl. sol. ether. Decomposed at 280°.

Reactions.—1. The K salt reacts with EtI forming $C_5H_5N_2SOEt$ [145°], and with MeI forming $C_5H_5N_2SOMe$ [220°], which yields $C_6H_7AgN_2SO$. — 2. *Chloro-acetic ether* forms $C_5H_5N_2SO(CH_2.CO_2Et)$ [143°], which yields $C_5H_5N_2SO(CH_2.CO_2H)$ [204°]. — 2. Br forms methyl-uracil, and finally di-oxy-methyl-uracil. Cl acts in like manner, forming $C_5H_6Cl_2N_2O_3$. —3. On warming with lead hydrate in strongly alkaline solution it is converted into methyl-uracil. Conc. HClAq at 150°, conc. NH_3Aq at 150°, and Ac_2O at 185° also form methyl-uracil.

Salts. — $C_5H_4Ag_2N_2SO$. — $C_5H_4CuN_2SO$. — $(C_5H_5N_2SO)_2Hg$. — $C_5H_5N_2NaSO$ 2aq. — $C_5H_5N_2KSO$ ½aq.

THIONAMIC ACID. H. Rose (*P.* 33, 235; 42, 415) found that SO_2 and NH_3 combined in equal volumes, when dry NH_3 was mixed with excess of dry SO_2, to form a yellowish white solid, which quickly decomposed in solution, or moist air, giving $(NH_4)_2SO_4$ and ammonium salts of other sulphur oxyacids. Rose concluded that the substance was $SO_2.NH_3$ from the fact that it was formed by combining equal volumes of the two gases; if this empirical formula is accepted the compound may be $SO_2.NH_2.H$ or $SO.OH.NH_2$. When dry SO_2 was mixed with excess of dry NH_3, Rose found that 1 vol. SO_2 combined with 2 vols. NH_3; the product—an amorphous, white solid—may be $SO_2.NH_2.NH_4$ or $SO.ONH_4.NH_2$.

M. M. P. M.

THIONAMIDE. By passing NH_3 into cooled S_2Cl_2 Schiff (*A.* 102, 111) obtained a white solid which was decomposed by warm water to $(NH_4)_2SO_3Aq$. The solid contained NH_4Cl; Schiff regarded it as a mixture of this salt with $SO(NH_2)_2$; he did not attempt to separate the supposed thionamide from NH_4Cl.

M. M. P. M.

(a)-THIO-NAPHTHOIC ACID.

Amide $C_{10}H_7CS.NH_2$. [126°]. Formed from (a)-naphthoic nitrile and alcoholic ammonium sulphide at 30°-35° (Hofmann, *B.* 1, 40; Bamberger, *B.* 21, 54). Crystals. v. sol. alcohol.

Tetrahydride of the amide  $\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}\!>C_6H_3.CS.NH_2$. Formed by digesting a solution of tetrahydride of (a)-naphthonitrile in alcoholic ammonia saturated with H_2S for some days at 30°-40° (Bamberger a. Bordt, *B.* 22, 629). Dark-yellow oil.

(β)-**Thio-naphthoic acid.** *Amide* $C_{10}H_7.CSNH_2$. [149°]. Formed from (β)-naphthonitrile and ammonium sulphide at 35°-40° (Bamberger a. Bockmann, *B.* 20, 1115). Needles, v. sol. alcohol. Dissolves in hot water, being slowly converted into the nitrile.

THIO-NAPHTHOL *v.* NAPHTHYL MERCAPTAN.

THIO-DI-NAPHTHYL-AMINE *v.* IMIDO-DI-NAPHTHYL SULPHIDE.

THIONATES. Salts of the *thionic acids* (*q. v.*, p. 698). Four series of thionates are known; a fifth probably exists: $M_2S_2O_6$ = dithionates; $M_2S_3O_6$ = trithionates; $M_2S_4O_6$ = tetrathionates; $M_2S_5O_6$ = pentathionates; and probably $M_2S_6O_6$ = hexathionates. The thionates are formed by the action of alkalis on the liquid obtained by passing H_2S into saturated SO_2Aq; also by the oxidation of sulphites, thiosulphates, and mixtures of these, and in other reactions (*cf.* THIONIC ACIDS, p. 698). For general qualitative reactions of thionates and thiosulphates *v.* Debus (*C. J.* 53, 298).

DITHIONATES, $M^I_2S_2O_6$, $M^{II}S_2O_6$, and $M^{III}_2(S_2O_6)_3$. (*Hyposulphates.*) The alkali salts are formed by the interaction of a dilute solution of I in KIAq and dilute $NaHSO_3Aq$ (Spring a. Bourgeois, *Bl.* [2] 46, 151; Sokoloff a. Mattscheffski, *B.* 14, 2058); also by the reaction of $KMnO_4Aq$ on thiosulphates in acetic acid solution, or on sulphites or trithionates (Hönig a. Zatzek, *M.* 4, 738; Fordos a. Gélis, *J. Ph.* [3] 36, 113). The Ba salt is formed by passing SO_2 into water holding MnO_2 in suspension, filtering, and adding BaOAq (for more details *v.* DITHIONIC ACID, p. 698); most of the other dithionates are obtained by the interaction of BaS_2O_6Aq and sulphates; several have been prepared by digesting $H_2S_2O_6Aq$ with metallic hydroxides. The dithionates are sol. water; the salts of the alkali and alkaline earth metals are not readily decomposed either in solution or as solids; solutions of most of the other salts are decomposed by heat, giving off SO_2 (*v.* Klüss, *A.* 246, 179, 284; Geuther, *A.* 226, 232).

Dithionates give off SO_2 when heated to redness, leaving normal sulphates; thus $M_2S_2O_6 = SO_2 + M_2SO_4$; this reaction is characteristic; so also is the reaction of H_2SO_4Aq or HClAq with boiling solutions of dithionates, whereby H_2SO_4Aq is formed and SO_2 is given off, without separation of S.

Ammonium dithionate $(NH_4)_2S_2O_6$. Obtained by decomposing the Ba salt in solution by $(NH_4)_2SO_4$Aq, filtering and crystallising. S.G. 1·704 (Topsoë, *C. C.* 4, 76). Klüss (*A.* 246, 179, 284) gives formula $2Am_2S_2O_6$.aq, and says the salt crystallises in monoclinic needles. Very sol. water; insol. alcohol. Aqueous solution may be boiled without change. Forms *double salts* with AmCl (Fock a. Klüss, *B.* 24, 3017); also with the dithionates of Al, Cd, Co, Cu, Fe, Mn, Ni, and Zn (K., *l.c.*).

Barium dithionate BaS_2O_6. 2aq. Formed by passing SO_2 into water at c. 0° holding coarsely-powdered MnO_2 in suspension, till the MnO_2 is dissolved ($MnO_2 + SO_2 + Aq = MnSO_4Aq$; and also $MnO_2 + 2SO_2 + Aq = MnS_2O_6Aq$), filtering if necessary, adding BaOAq to alkaline reaction ($MnS_2O_6Aq + BaO_2H_2Aq = BaS_2O_6Aq + MnO_2H_2$), filtering from MnO_2H_2, evaporating, and recrystallising from water (*cf.* Stas, *Chem. Proport.* 117). White prisms; S. 24·75 at 18°, 90·9 at 100°, 100·6 at 102° = b.p. of saturated solution; insol. alcohol. The crystals effloresce in air, losing $2H_2O$; a hydrate with $4H_2O$ is obtained by slow evaporation (*v.* Heeren, *P.* 7, 55; Gay-Lussac, *A. Ch.* [2] 10, 312; Baker, *C. N.* 36, 203; *cf.* Spring a. Bourgeois, *Bl.* [2] 46, 151. For crystalline form *v.* Senarmont, *J.* 1857. 142; Rammelsberg, *P.* 58, 295; von Lang, *W. A. B.* 45 [2] 27). Schiff (*A.* 105, 239) described *double salts* with MgS_2O_6 and $Na_2S_2O_6$ (*cf.* Kraut, *A.* 118, 95); Bodländer (*Chem. Zeit.* 14, 1140) described a double salt with $Rb_2S_2O_6$; and Klüss (*A.* 246, 179, 284) double salts with $Ag_2S_2O_6$ and $Tl_2S_2O_6$.

Many of the other dithionates are prepared from the Ba salt.

Potassium dithionate $K_2S_2O_6$. Prepared from a solution of the Ba salt by adding an equivalent quantity of K_2SO_4 in solution, warming, filtering, and evaporating; also by boiling K_2SO_3Aq with MnO_2 filtering, and separating from K_2SO_4 by fractional crystallisation (K_2SO_4 is much less sol. water than $K_2S_2O_6$). White, hexagonal crystals; unchanged in air; decrepitates when heated and then gives off SO_2 and leaves K_2SO_4; S.G. 2·277 (Topsoë, *Bl.* [2] 19, 246). The crystals rotate the plane of polarisation of light; an aqueous solution is optically inactive (Pape, *P.* 139, 224). S. c. 6 at ordinary temperature, c. 66 at 100°; insol. alcohol (Heeren, *P.* 7, 55).

Sodium dithionate $Na_2S_2O_6$. 2aq. Prepared similarly to the K salt. Also formed, according to Bunte (*B.* 7, 646), by heating $Na.Et.S_2O_3$ for some time at 100° (Et_2S_2 distils off). Large, lustrous, rhombic prisms; unchanged in air, S.G. 2·175 at 11° (Baker, *C. N.* 36, 203). S. 47·6 at 16°; 90·9 at 100°; insol. alcohol. Solution is slowly reduced by sodium-amalgam to Na_2SO_3Aq (Spring, *B.* 7, 1161). Kraut (*A.* 117, 97) described a hydrate with $6H_2O$.

Dithionates of the following metals have also been described (the figures indicate the references): Al (1) (3); Be (3); Bi (3); Cd (1) (2) (4); Ca (1) (4) (5); Cr (3); Co (1) (2) (3) (4); Cu (3); Fe (1) (3) (4); Pb (1) (4) (5); Li (2) (4); Mg (1) (4) (5); Mn (4); Hg (1) (2) (3); Ni (2) (4) (5); Rb (6); Ag (1) (2) (4) (5); Sr (2) (4); Tl (3); Sn (3); U (3); Zn (1) (2) (4).

(1) Heeren, *P.* 7, 72, 171; (2) Rammelsberg, *P.* 58, 298; (3) Klüss, *A.* 246, 179, 284; (4) Topsoë, *C. C.* 4, 76; (5) Baker, *C. N.* 36, 203; (6) Piccard, *J. pr.* 86, 456.

TRITHIONATES $M^I_2S_3O_6$ and $M^{II}S_3O_6$. The alkali salts are formed by digesting conc. $MHSO_3$Aq with S at 50°–60° ($6MHSO_3Aq + 2S = 2M_2S_3O_6Aq + M_2S_2O_3Aq + 3H_2O$)(Pelouze, *A. Ch.* [3] 79, 85); also by heating dilute $MHSO_3$Aq, or keeping the solution for a long time in a closed tube (Saint-Pierre, *C. R.* 62, 632); by passing SO_2 into $M_2S_2O_3$Aq ($2M_2S_2O_3Aq + 3SO_2 = 2M_2S_3O_6Aq + S$); by passing SO_2 into M_2SAq (Chancel a. Diacon, *J. pr.* 90, 35; Rathke, *J. pr.* 95, 11); by the interaction of I and a mixture of M_2SO_3 and $M_2S_2O_3$ in solution ($M_2SO_3Aq + M_2S_2O_3Aq + I_2 = M_2S_3O_6Aq + 2MIAq$) (Spring, *B.* 7, 1157); by the interaction of boiling water on $AgKS_2O_3$ or $HgNa_2(S_2O_3)_2$, whereby $K_2S_3O_6$Aq or $Na_2S_3O_6$Aq is formed, along with Ag_2S or HgS (Spring, *l.c.*); by reacting on M_2SO_3Aq with S_2Cl_2 (Spring, *B.* 6, 1108); by decomposing $M_2S_2O_3$Aq by a non-oxidising acid, *e.g.* by H_2SO_4 (Spring a. Levy, *Bull. de l'Acad. roy. de Belge*, 42, 108); by heating $(NH_4)_2SO_4$ with P_2S_5, Spring (*B.* 7, 1158) obtained a little $(NH_4)_2S_3O_6$, along with much $(NH_4)_2S_2O_3$, some NH_4 polysulphides, and P compounds; $K_2S_3O_6$ is also obtained from Wackenroder's solution.

The trithionates are soluble in water; they very readily decompose; heated with water they give off SO_2, deposit S, and form sulphates in solution. Addition of excess of $CuSO_4$Aq to solution of a trithionate causes ppn. of CuS and evolution of SO_2 (Spring, *B.* 6, 1108).

SELENOTRITHIONATES $M_2SeS_2O_6$ are described as *dithio-triselenates* under SELENATES (p. 434).

Potassium trithionate $K_2S_3O_6$. A conc. solution of $K_2S_2O_3$ is formed by dissolving the salt in 8 pts. water and 1 pt. alcohol till the alcohol separates from the aqueous solution; SO_2 is passed into this solution at 25°–30°, solid $K_2S_2O_3$ being added from time to time, till the liquid is yellow and smells of SO_2; the crystals that separate are dissolved in water at 60°–70°, the solution is filtered from S, mixed with eight times its volume of 84 p.c. alcohol, warmed gently, and allowed to crystallise (Plessy, *A. Ch.* [3] 20, 162; for other methods of preparation *v.* Langlois, *A. Ch.* [2] 79, 77; Rathke, *J.* 1864. 164; Chancel a. Diacon, *C. R.* 56, 710). White rhombic needles (Baker, *C. N.* 36, 203). Very sol. water, insol. alcohol. Aqueous solution gives K_2SO_4Aq, SO_2, and S when heated. Debus (*C. J.* 53, 313) found that $K_2S_3O_6$Aq slowly changes at the ordinary temperature, giving K_2SO_4Aq, $K_2S_4O_6$Aq, and $K_2S_5O_6$Aq without separation of S. According to C. a. D. (*l.c.*), $K_2S_3O_6$Aq interacts with K_2S_2Aq to give only $K_2S_2O_3$Aq; with H_2S the products are K_2SO_4Aq, $K_2S_2O_3$Aq, and S (Debus, *C. J.* 53, 329). Sodium-amalgam reacts readily, producing $KNaS_2O_3$ and $KNaSO_3$ (Spring, *B.* 7, 1161).

The other trithionates that have been isolated are those of Ba (Kessler, *P.* 74, 253); Pb (K., *l.c.*; Chancel a. Diacon, *C. R.* 56, 710); Na (K., *l.c.*; Rathke, *J. pr.* 95, 13; Villiers, *C. R.* 106, 1356); and Zn (Fordos a. Gélis, *A. Ch.* [3] 22, 66).

TETRATHIONATES $M^I_2S_4O_6$ and $M^{II}S_4O_6$. The alkali salts are formed by triturating $M_2S_2O_3$ with I, adding a little water and pouring into alcohol (von Klobukoff, *B.* 18, 1869; Eliasberg, *B.* 19, 322; Fock a. Klüss, *B.* 23, 2429); the Pb salt is formed by the prolonged interaction of I and PbS_2O_3, also by the interaction of H_2SO_4Aq and a mixture of PbS_2O_3 with PbO_2 (Chancel a. Diacon, *J. pr.* 90, 55); tetrathionates are also formed, according to Spring a. Levy (*Bull. de l'Acad. roy. de Belge*, 42, 108), by the interaction of thiosulphates and ferrous or cuprous salts, $KMnO_4Aq$, hypochlorites, or $KClO_3$ dissolved in H_2SO_4Aq. $K_2S_4O_6$ is obtained by neutralising Wackenroder's solution by $KC_2H_3O_2$ (*v.* Debus, *C. J.* 53, 278; *cf.* Curtius a. Henkel, *J. pr.* [2] 37, 137). The tetrathionates are e. sol. water, but insol. alcohol; aqueous solutions are generally decomposed on evaporation.

Potassium tetrathionate $K_2S_4O_6$. Formed by adding I, little by little, to conc. $K_2S_2O_3Aq$ till a permanent reddish-brown colour is produced, dissolving the crystals that separate in warm water, filtering from S, adding alcohol till the pp. that forms is re-dissolved, and allowing to crystallise (Kessler, *P.* 74, 253). Spontaneous decomposition of conc. $K_2S_5O_6Aq$ gives $K_2S_4O_6$ and S (Debus, *C. J.* 53, 311). Perfectly dry $K_2S_4O_6$ can be kept unchanged in a dry atmosphere; but in ordinary air, after a time, SO_2 is formed; an aqueous solution of $K_2S_4O_6$ slowly changes to $K_2S_3O_6Aq$, $K_2S_5O_6Aq$, K_2SO_4Aq, and SO_2 (D., *l.c.*). BrAq reacts to form H_2SO_4Aq, S, and KBr; but if the BrAq is added very gradually the S that is formed combines with residual $K_2S_4O_6$ to form $K_2S_5O_6$; similarly, if a little K_2SO_4 is added to $K_2S_4O_6Aq$, and H_2S is then passed in, K_2SO_4 and S are formed, and the S combines with unchanged $K_2S_4O_6$ to form $K_2S_5O_6$ (D., *l.c.* p. 315). Sodium-amalgam forms $KNaS_2O_3Aq$ (Spring, *B.* 7, 1161).

The other tetrathionates that have been isolated are those of Ba (Lewes, *C. J.* 39, 69; Fordos a. Gélis, *A. Ch.* [3] 22, 66; Curtius a. Henkel, *J. pr.* [2] 37, 137); Cd (Kessler, *P.* 74, 253); Cu (Chancel a. Diacon, *C. R.* 56, 510); Fe (F. a. G.); Pb (K.; C. a. D.); Na (K.; von Klobukoff, *B.* 18, 1869); Sr (K.); and Zn (F. a. G.).

PENTATHIONATES $M^I_2S_5O_6$ and $M^{II}S_5O_6$. Wackenroder, in 1845 (*A.* 60, 189), asserted that the liquid formed by passing H_2S into SO_2Aq contained pentathionic acid $H_2S_5O_6$; other chemists confirmed his results, and prepared a few salts of the acid (*v.* Lenoir, *A.* 62, 253; Fordos a. Gélis, *A. Ch.* [3] 22, 66; Kessler, *P.* 74, 257; Ludwig, *Ar. Ph.* [2] 85, 9; Chancel a. Diacon, *C. R.* 56, 710). At a later time the existence of pentathionates was denied, chiefly by Spring (*B.* 12, 2254; 13, 924; 15, 2618), but upheld by Kessler (*B.* 13, 424; *v.* also Takatmatsu a. Smith, *B.* 13, 1976). In 1881 Lewes (*C. J.* 39, 68) seemed to have isolated BaS_5O_6 and $K_2S_5O_6$, but Spring failed to confirm his results. Shaw, however (*C. J.* 43, 357), repeated Lewes's experiments, and obtained $K_2S_5O_6$. In 1888 Debus (*C. J.* 53, 278) made an elaborate investigation of Wackenroder's solution, and prepared $K_2S_5O_6$ therefrom. Curtius a. Henkel (*J. pr.* [2] 37, 137) assert that Wackenroder's solution contains acid tetrathionates, in which the ratio of S to Ba is greater than 4S:Ba, and that these have been mistaken for pentathionates. But Debus's experiments seem to have settled the dispute in favour of the existence of pentathionates. Ammoniacal $AgNO_3Aq$ gives very distinct brown colouration, followed by a black pp. with pentathionates; this reaction distinguishes them from salts of other S oxyacids (*v.* Debus, *l.c.*, p. 297).

Potassium pentathionate $2K_2S_5O_6.3aq$. Debus (*C. J.* 53, 294) prepared this salt from *Wackenroder's solution* (*v.* p. 698) by adding 16·66 g. $KC_2H_3O_2$ (previously fused) to 43 c.c. of the solution of S.G. 1·343; the $KC_2H_3O_2$ was dissolved in as little water as possible acidulated with a few drops of acetic acid; the solution was placed in a large flat dish in a current of air until the liquid had evaporated; the crystalline residue (weighing 26 g.) was repeatedly pressed between filter-paper, and then dissolved in 50 c.c. water + 1 c.c. H_2SO_4, at 40°; the minute quantity of S that separated (c. ·005 g.) was filtered off, and the filtrate was allowed to crystallise in a flat dish. The crystals that separated (18·75 g.) were a mixture of $K_2S_4O_6$ and $K_2S_5O_6$; they were dried by placing them on blotting paper, and the crystals of pentathionate were picked out (5·75 g. were obtained), crystallised twice from water acidulated with a little H_2SO_4Aq, and dried over H_2SO_4. The crystals of pentathionate form four-sided rhombic plates, or six-sided star-like plates; those of tetrathionate form six-sided prisms, with pyramids only on one end, and with the side on which they rest much developed. Lewes (*C. J.* 39, 75) described three salts: $K_2S_5O_6$, $K_2S_5O_6.H_2O$, and $K_2S_5O_6.2H_2O$; Debus's salt was $2K_2S_5O_6.3H_2O$. According to Fock a. Klüss (*B.* 23, 2428), this is the only salt that exists (*cf.* D., *l.c.*, p. 297). The salt can also be obtained by passing H_2S into $K_2S_4O_6Aq$ acidulated with H_2SO_4Aq (D., *l.c.*, p. 315).

Crystals of $2K_2S_5O_6.3H_2O$ begin to decompose, when kept in a stoppered bottle, after a month or so, giving eventually a yellow, pulpy mass of $K_2S_4O_6$, S, and water; the decomposition is caused by water in the interstices of the crystals. By powdering finely, washing with dilute alcohol, and placing over H_2SO_4, Debus (*l.c.* p. 295) kept the salt unchanged for two or three years. $2K_2S_5O_6.3H_3O$ dissolves in c. 2 parts water, forming a clear, neutral solution, which soon decomposes with separation of S and formation of $K_2S_4O_6Aq$ (D., *l.c.*, p. 311); addition of a drop of dilute KOHAq to the solution causes separation of S (p. 291); H_2S ppts. much S, and $K_2S_3O_6$ and $K_2S_2O_3$ are formed in the solution (p. 328); SO_2 produces $K_2S_3O_6Aq$ and $K_2S_2O_3Aq$ (p. 332); the salt is insoluble in alcohol.

Barium pentathionate $BaS_5O_6.3aq$; obtained by Lewes (*C. J.* 39, 68) by partially neutralising Wackenroder's solution by BaOAq, crystallising over H_2SO_4, pouring off from BaS_4O_6, and again crystallising.

Copper pentathionate $CuS_5O_6.4aq$; obtained by Debus (*l.c.*, p. 300) in blue, prismatic crystals, by adding $Cu(C_2H_3O_2)_2Aq$ to Wackenroder's solution and allowing to evaporate. Debus probably obtained *zinc pentathionate*, but not in a pure state (*l.c.*, p. 299).

HEXATHIONATES. By adding $KC_2H_3O_2Aq$ to the mother-liquor from $K_2S_4O_6$ and $K_2S_5O_6$ (*v. supra*), evaporating in a current of air, dis-

solving in water with a little H_2SO_4Aq, allowing to evaporate in portions, and collecting the crystals separately, Debus (*C. J.* 53, 301) obtained a salt in which the ratio of S to O was almost 6S:6O, as required by *potassium hexathionate*.

M. M. P. M.

THIONESSAL *v.* Tetra-phenyl-thiophene.

THIONIC ACIDS. The acids $H_2S_xO_6$, where $x = 2, 3, 4, 5$, and probably 6, are generally called thionic acids, and are distinguished as *di-*, *tri-*, &c., thionic acid. The acids are known only in aqueous solutions; most of these solutions readily oxidise to H_2SO_4Aq. Dithionic acid is produced by the action of certain oxidisers on H_2SO_3Aq; dithionates are formed by oxidising sulphites and thiosulphates; trithionates are formed when mixtures of sulphites and thiosulphates are oxidised, also when SO_2Aq interacts with alkali thiosulphates; tetrathionates result by the action of certain oxidisers on thiosulphates. These processes may be represented diagrammatically as follows (the actual reactions are much more complex):

(1) $2H_2SO_3Aq + O = H_2S_2O_6Aq + H_2O$;

(2) $2M_2SO_3Aq + O = M_2S_2O_6Aq + M_2O$;
$M_2S_2O_3Aq + 3O = M_2S_2O_6Aq$;

(3) $M_2SO_3Aq + M_2S_2O_3Aq + O = M_2S_3O_6Aq + M_2O$;
$2M_2S_2O_3Aq + 3SO_2Aq = 2M_2S_3O_6Aq + S$;

(4) $2M_2S_2O_3Aq + O = M_2S_4O_6Aq + M_2O$.

After passing H_2S for a long time into nearly saturated H_2SO_3Aq, the solution contains $H_2S_3O_6$, much $H_2S_4O_6$, $H_2S_5O_6$, and probably $H_2S_6O_6$, along with H_2SO_4, dissolved colloidal S, and a little S in suspension. This solution is known as *Wackenroder's solution* (Wackenroder, *A.* 60, 189 [1845]). It has been examined by many chemists; a very thorough investigation was made by Debus in 1888 (*C. J.* 53, 278; where references will be found to other memoirs). The solution examined by Debus was prepared by passing a slow current of H_2S into 480 c.c. nearly saturated SO_2Aq at a little above 0° for two hours, keeping in a stoppered bottle for forty-eight hours at the ordinary temperature, passing in H_2S for two hours, after forty-eight hours again passing in H_2S, and repeating these treatments until the liquid no longer smelled of SO_2 after standing for a couple of hours at the ordinary temperature (about two weeks were required before the action was completed). The liquid thus obtained contains a large quantity of S, partly as a hard brittle solid, partly as a soft and gummy mass, and partly in suspension in minute particles which pass through filter paper; the liquid remains milky after filtration, and does not become clear on standing for two or three weeks (regarding the variety of S in solution, *v.* Sulphur, *Allotropic forms of*, p. 608). Debus (*l.c.*, p. 348) thinks that the product of the direct interaction of SO_2Aq and H_2SAq is $H_2S_4O_6$ ($3SO_2Aq + H_2SAq = H_2S_4O_6Aq$); that part of this $H_2S_4O_6$ reacts with excess of SO_2Aq to form $H_2S_3O_6Aq$ and $H_2S_2O_3Aq$ (? $H_2S_4O_6Aq + H_2SO_3Aq = H_2S_3O_6Aq + H_2S_2O_3Aq$), and that part of the $H_2S_4O_6Aq$ reacting with $H_2S_2O_3Aq$ forms $H_2S_5O_6Aq$ (? $H_2S_4O_6Aq + H_2S_2O_3Aq = H_2S_5O_6Aq + H_2SO_3Aq$) (D., *l.c.*, p. 333); that the H_2S reacts with $H_2S_4O_6Aq$ to form H_2O and S, part of the S combining, as it is formed, with $H_2S_3O_6Aq$ to form $H_2S_4O_6Aq$, $H_2S_5O_6Aq$ and $H_2S_6O_6Aq$, and part remaining in solution as colloidal S. If H_2S is passed into Wackenroder's solution, more $H_2S_5O_6$ is formed; and if the passage of H_2S is continued until all reaction ceases the thionic acids are decomposed, and the final products are S and H_2O, so that the equation $SO_2Aq + 2H_2SAq = 3S + 2H_2OAq$ correctly represents the interaction of SO_2Aq with H_2SAq so far as the final products are concerned (*v.* D., *l.c.*, p. 351).

Solutions of the thionic acids more or less rapidly decompose, the final products being H_2SO_4Aq, SO_2Aq, and S; oxidisers such as Cl or HNO_3Aq—in some cases air is sufficient—convert them into H_2SO_4Aq; reducers, such as Na amalgam, produce $H_2S_2O_3Aq$, sometimes also H_2SO_3Aq, and in some cases H_2SAq. None of the acids has been isolated apart from water; salts of all are known (*v.* Thionates, p. 695). The acids are all dibasic.

Regarding the constitution of the thionic acids *v.* Mendeléeff, *B.* 3, 870; Michaelis, *A.* 170, 31; Spring, *B.* 6, 1108; Debus, *C. J.* 53, 351.

Dithionic acid $H_2S_2O_6Aq$. (*Hyposulphuric acid.*) A solution of this acid is formed by suspending coarsely-powdered MnO_2 in water, and passing in SO_2 while the liquid is kept at c. 0°; filtering, adding BaOAq to alkaline reaction, and filtering from $BaSO_4$ and MnO_2H_2; evaporating, crystallising out $BaS_2O_6.2aq$, and decomposing this salt in solution by the equivalent quantity of H_2SO_4Aq; filtering from $BaSO_4$, and evaporating *in vacuo* till a liquid of S.G. 1·347 is obtained ($MnO_2 + 2SO_2Aq = MnS_2O_6Aq$; $MnO_2 + SO_2Aq = MnSO_4Aq$) (Spring a. Bourgeois, *Bl.* [2] 46, 151). If evaporation is continued beyond this concentration, H_2SO_4Aq and SO_2 are formed; the same decomposition occurs when $H_2S_2O_6Aq$ is evaporated by heat. $H_2S_2O_6Aq$ is reduced by Zn and HClAq to H_2SO_3Aq at 0° (Otto, *A.* 147, 187); it is oxidised to H_2SO_4Aq by Cl, HNO_3, $KClO_3$ and HCl &c.; it slowly oxidises in air (*cf.* Dithionates, p. 695). Thomsen (*Th.* 2, 259) gives the following heats of formation of $H_2S_2O_6Aq$:—$[S^2,O^5,Aq] = 211,080$; $[2SO^2,O,Aq] = 68,920$; $[2SO^2Aq,O] = 53,520$; for the heat of oxidation of $H_2S_2O_6Aq$ to H_2SO_4Aq he gives ($S_2O_5Aq + O = 2SO_3Aq$) $[S^2O^5Aq,O] = 73,740$.

Trithionic acid $H_2S_3O_6Aq$. A dilute solution of this acid is formed by decomposing $K_2S_3O_6Aq$ by the equivalent quantity of $HClO_4Aq$ or H_2SiF_6Aq, and filtering from $KClO_4$ or K_2SiF_6 (Langlois, *C. R.* 10, 461; 62, 842; Kessler, *P.* 74, 250). The dilute solution cannot be evaporated, even *in vacuo*, without partial decomposition, with formation of SO_2 and S; when heated it rapidly changes to H_2SO_4Aq, SO_2 and S. The dilute solution is colourless and odourless, and has a sour and bitter taste (*cf.* Trithionates, p. 696). The K salt, from which the acid solution is obtained, may be prepared by dissolving $K_2S_2O_3$ in water containing one-eighth part of alcohol, adding the salt till the alcohol separates from the aqueous solution, passing in SO_2, with addition from time to time of a little $K_2S_2O_3$, temperature being kept at 25°-30°, till the liquid is yellow and smells of SO_2, setting aside till crystals separate, and re-crystallising from warm water (filtering from separated S) (Plessy, *A. Ch.* [3] 11, 182).

Tetrathionic acid $H_2S_4O_6Aq$. PbS_4O_6Aq is decomposed by the equivalent quantity of H_2SO_4Aq (not by H_2S, which reacts with $H_2S_4O_6$), and the filtrate from $PbSO_4$ is concentrated on the water-bath, and then *in vacuo* over H_2SO_4 (Fordos a. Gélis, *C. R.* 115, 920). PbS_4O_6 may be prepared by pouring a solution of 2 pts. $Na_2S_2O_3.5H_2O$ in much warm water into a dilute warm solution of 3 pts. lead acetate, and thoroughly washing the ppd. PbS_2O_3 with warm water, adding water enough to partially dissolve the PbS_2O_3, then adding 1 pt. I, and letting stand for some days, with frequent shaking, filtering from PbI_2, evaporating and crystallising ($2PbS_2O_3 + 2I + Aq = PbS_4O_6Aq + PbI_2$).

$H_2S_4O_6Aq$ is colourless and odourless; it has a sour taste. Dilute $H_2S_4O_6Aq$ may be boiled without change, but the conc. solution decomposes to H_2SO_4Aq, SO_2, and S. Dilute HClAq or H_2SO_4Aq does not interact with cold $H_2S_4O_6Aq$; on warming H_2S is given off; HNO_3Aq or Cl rapidly oxidises $H_2S_4O_6Aq$ to H_2SO_4Aq (*cf.* Tetrathionates, p. 696). Thomsen (*Th.* 2 262) gives the following data for H.F.:— $[S^4,O^5,Aq] = 192,430$; $[2SO^2,S^2,O,Aq] = 50,270$; $[2SO^2Aq,S^2,O] = 34,870$; $[2S^2O^2Aq,O] = 53,490$.

Pentathionic acid $H_2S_5O_6Aq$, and Hexathionic acid $H_2S_6O_6Aq$. These acids very probably exist in *Wackenroder's solution* (*v. supra*, p. 698), as salts of $H_2S_5O_6$, and probably also of $H_2S_6O_6$, have been obtained from that solution; solutions of the acids have not been isolated (*v.* Pentathionates, p. 697, and Hexathionates, p. 697).

M. M. P. M.

THIONINE. The group 
$\begin{array}{l} S\text{————}C_6H_3 \\ C_6H_3(NH_2).N\text{——} \end{array}\!\!>NH$

i.e. 
$C_6H_3(NH_2)\!<\!\begin{array}{c}S\\N\end{array}\!\!>\!C_6H_3{:}NH$ (Bernthsen a. Goske, *B.* 20, 931).

THIONOL $C_{12}H_7NSO_2$ *i.e.* 
$\begin{array}{l} S\text{————}C_6H_3 \\ C_6H_3(OH).N\text{——} \end{array}\!\!>O.$

Formed by heating imido-di-phenyl sulphide with dilute H_2SO_4 at 150°-160° (Bernthsen, *A.* 230, 188). Brownish-red powder, which acquires green lustre on rubbing. Insol. cold water, sol. acids and alkalis, forming a violet solution. Yields di-oxy-imido-diphenyl sulphide (*q. v.*) on reduction.—$B'_2H_2SO_4$. Green needles.—$B'BaO$ (dried at 100°). Plates with green lustre.—$B'Ag_2O$ (dried at 100°). Brown amorphous pp.

THIONOLINE *v.* Oxy-amido-imido-diphenyl sulphide.

THIONURIC ACID $C_4H_5N_3SO_6$ *i.e.* 
$CO\!<\!\begin{array}{l}NH.CO\\NH.CO\end{array}\!\!>\!CH.NH.SO_3H$. Formed by the simultaneous action of NH_3 and SO_2 on alloxan in aqueous solution (Liebig a. Wöhler, *A.* 26, 268, 314, 331). Formed also by warming nitroso-barbituric acid with ammonium sulphite (Baeyer, *A.* 127, 210). Crystalline mass of needles, v. sol. water. Decomposed by boiling water into uranil and H_2SO_4. Reduces ammoniacal $AgNO_3$ to a mirror.—$(NH_4)_2A''aq$. Four-sided tables, sl. sol. cold water. At 200° it yields $(NH_4)_2SO_4$ and xanthinine (Finck, *A.* 132, 298).—$(NH_4)HA''$. White needles.—CaA''. Prisms.—$PbA''aq$.

THIONYL-*m*-AMIDO-BENZOIC ACID $SO{:}N.C_6H_4.CO_2H$.

Methyl ether MeA'. [57°]. (212° at 100 mm.). Formed from methyl *m*-amido-benzoate and $SOCl_2$ (Michaelis, *A.* 274, 250). Yellow crystalline mass, v. sol. ether and benzene.

Ethyl ether EtA'. Oil.

THIONYL-DIAMIDO-DI-PHENYL-ETHYLENE $C_2H_4(C_6H_4.N{:}SO)_2$. [202°]. Formed from di-amido-stilbene and $SOCl_2$ (Michaelis, *A.* 274, 265). Red needles, m. sol. benzene and $CHCl_3$.

THIONYL-AMIDO-PHENOL. *Ethyl derivative* $C_6H_4(OEt).N{:}SO$. [32°]. (220° at 200 mm.). Formed from *p*-amido-phenetol and $SOCl_2$ (Michaelis, *A.* 274, 246). Light-yellow needles, v. sol. ether. Slowly decomposed by water.

THIONYL-AMYLAMINE $SO{:}NC_5H_{11}$. (87° at 60 mm.). Formed from amylamine (103°) in ether and $SOCl_2$ (Michaelis, *A.* 274, 191). Oil, decomposed by water.

THIONYL-ANILINE $C_6H_5N{:}SO$. (200°). S.G. ^{15} 1·236. Formed from aniline in benzene solution and $SOCl_2$ (Michaelis, *B.* 23, 3480; 24, 745). Liquid with peculiar odour, sol. alcohol. Converted by alkalis into aniline and sulphite. Chlorine forms tri-chloro-aniline [78°]. Conc. HClAq also forms aniline and SO_2. The compound $C_6H_2Br_3N{:}SO$ [75°] is formed from tri-bromo-aniline in benzene and $SOCl_2$. The compounds [1:2]$C_6H_4Cl.N{:}SO$ [−8°], [1:3] $C_6H_4Cl.N{:}SO$ (233°) and [1:4] $C_6H_4Cl.N{:}SO$ [36°] (237°) are formed in like manner. *o*-, *m*-, and *p*- Thionyl-bromo-anilines melt at 4°, 32°, and 61° respectively (Michaelis, *A.* 274, 221). Thionyl-tetra-bromo-aniline melts at 78°. Thionyl-*p*-iodo-aniline [54°] and [4:2:1] $C_6H_3I_2N{:}SO$ [74°] are also crystalline.

Reference.—Nitro-thionyl-aniline.

THIONYL BROMIDE $SOBr_2$ *v.* Sulphur oxybromides, p. 617.

THIONYL-ISOBUTYLAMINE C_4H_9NSO *i.e.* $CHMe_2.CH_2.N{:}SO$. (116°). Formed from $SOCl_2$ and isobutylamine in ether (Michaelis, *A.* 274, 191). Liquid, with pleasant smell.

THIONYL CHLORIDE $SOCl_2$ *v.* Sulphur oxychlorides, p. 617.

THIONYL-CUMIDINE $C_6H_4Pr.N{:}SO$. (158°). Got from $SOCl_2$ and the cumidine obtained from isopropyl-benzene by nitration and reduction (Michaelis, *A.* 274, 239). Oil, not decomposed by boiling water.

Thionyl-ψ-cumidine $C_6H_2Me_3.N{:}SO$. [−10°]. (246°). Oil, v. sol. alcohol and ether.

THIONYL-ETHYLAMINE $EtN{:}SO$. (73°). Formed by adding $SOCl_2$ to an ethereal solution of ethylamine cooled below 0° (Michaelis, *B.* 24, 756).

THIONYL-MESIDINE $C_6H_2Me_3.N{:}SO$. [−11°]. (241°). S.G. ^{14} 1·121. Volatile with steam (Michaelis, *A.* 274, 240).

THIONYL-METHYLAMINE $MeN{:}SO$. (59°). Liquid (Michaelis, *A.* 274, 187).

THIONYL-METHYL-ANILINE $SO(C_6H_4.NHMe)_2$. [154°]. Formed from $SOCl_2$ and methyl-aniline in ethereal solution in presence of $AlCl_3$ (Michaelis a. Godchaux, *B.* 23, 3019). Colourless needles, v. sol. alcohol. Yields a nitrosamine $SO(C_6H_4.NMe.NO)_2$. [171°].

THIONYL-(α)-NAPHTHYLAMINE $C_{10}H_7.N{:}SO$. [33°]. (226° at 100 mm.). Formed from (α)-naphthylamine in benzene and $SOCl_2$ (Michaelis, *A.* 274, 253). Reddish yellow needles, slowly converted by water into naphthylamine sulphite.

Thionyl-(β)-naphthylamine [53°]. Needles. The thionyl derivative of bromo-(β)-naphthylamine [63°] melts at 118°.

THIONYL-*o*-NITRO-ANILINE $C_6H_4N_2SO_3$ *i.e.* $C_6H_4(NO_2)$.N:SO. [62°], the *m-* compound melts at 63°, while the *p*-isomeride melts at 70° (Michaelis, *A.* 274, 225).

THIONYL-NITRO-MESIDINE $C_9H_{10}N_2SO_3$ *i.e.* $C_6HMe_2(NO_2)$.N:SO. [77°]. Got from nitro-mesidine [74°] (Michaelis, *A.* 274, 241). Light yellow needles, v. e. sol. benzene.

Thionyl-di-nitro-mesidine. [127°]. Formed from di-nitro-mesidine [193°].

THIONYL-NITRO-NAPHTHYLAMINE $C_{10}H_6(NO_2)$.N:SO. Nitro-naphthylamines [191°] and [119°] yield thionyl derivatives melting at 89° and 135° respectively (Michaelis, *A.* 274, 258).

THIONYL-NITRO-TOLUIDINE $C_7H_6N_2SO_3$ *i.e.* $C_6H_3Me(NO_2)$.N:SO. The compounds from (2,1,4)-nitro-toluidine [75°] and (3,1,4)-nitro-toluidine [114°] melt at 44° and 39° respectively (Michaelis, *A.* 274, 232).

DI-THIONYL-PHENYLENE-DIAMINE $C_6H_4(N:SO)_2$. The *m-* and *p-* compounds melt at 44° and 116° respectively (Michaelis, *A.* 274, 261).

THIONYL-PHENYLETHYL-AMINE $PhCH_2.CH_2.N:SO$. (172° at 25 mm.). Liquid, decomposed by water into SO_2 and base. SO_2 passed into its ethereal solution forms amorphous $PhCH_2.CH_2.NH.SO_2H$, whence benzoic aldehyde yields $PhCH_2.CH_2.N(SO_2H).CHPh.OH$ [114°] (Michaelis, *B.* 26, 2167).

THIONYL-PHENYL-HYDRAZINE *v.* Action of $SOCl_2$ on PHENYL-HYDRAZINE.

THIONYL-PHENYL-PROPYLAMINE $CH_2Ph.CH_2.CH_2.N:SO$. Formed from phenyl-propylamine hydrochloride and $SOCl_2$ (Michaelis a. Jacobi, *B.* 26, 2161). SO_2 passed into its ethereal solution forms the amorphous compound $NH(SO_2H).C_3H_6Ph$, which reacts with benzoic aldehyde forming $SO_2H.N(CHPh.OH).C_3H_6Ph$ [106°].

THIONYL-PROPYLAMINE PrN:SO. (104°). Smells like bleaching-powder (Michaelis, *A.* 274, 190).

THIONYL-TOLUIDINE $C_6H_4Me.N.SO$. Formed from toluidine and $SOCl_2$. The *o-* compound is liquid (184° at 100 mm.). The *m-* compound is liquid (220°). The *p-* isomeride [7°] (c. 224°) may be crystallised by cooling (Michaelis a. Herz, *B.* 23, 3482; 24, 753; *A.* 274, 231). The thionyl derivatives of (3,1,4)- and (5,1,2)-bromo-toluidines melt at 47° and 50° respectively.

THIO-ORCIN $C_6H_3Me(SH)_2$. [35°]. Formed by reducing $C_6H_3Me(SO_2Cl)_2$ with tin and HClAq (Gabriel, *B.* 12, 1640).—$PbC_7H_6S_2$.

THIONYL-XYLIDINE $C_6H_3Me_2N:SO$. The (1,2,4)- compound [−9°] (131° at 20 mm.), (1,3,4)- compound (238°), and (1,4,2)- isomeride [−8°] (119° *in vacuo*) are all oily (Michaelis, *A.* 274, 237). Thionyl-fluoro-xylidine (144° at 45 mm.) is also an oil.

THIO-OXALIC ACID. *Ethyl ether* $C_6H_{10}SO_3$ *i.e.* $CO_2Et.CO.SEt$. (217° cor.). S.G. $\frac{0}{0}$ 1·145. Formed by the action of $Cl.CO.CO_2Et$ on mercaptan (Morley a. Saint, *C. J.* 43, 400). Colourless liquid with faint odour like garlic. Decomposed by KOHAq into mercaptan, alcohol, and oxalate. Alcoholic KOH (1 mol.) forms EtSH and $CO_2Et.CO_2K$. Water slowly decomposes it, forming oxalic acid, alcohol, and mercaptan. Dry NH_3 forms mercaptan and $CO_2Et.CONH_2$.

(β)-Thio-oxalic acid $NH_2.CS.CO_2H$. The salt $C_2H_2KNSO_2$ is formed by the action of cold conc. KOHAq on the ethers. It crystallises in needles, v. sol. water and decomposed by evaporating. The free acid is unstable.

Amide of the methyl ether. $NH_2.CS.CO_2Me$. [86°]. Formed by passing dry H_2S into $Cy.CO_2Me$ (Weddige, *J. pr.* [2] 7, 79; 9, 133; 10, 193). Light-yellow crystals, sol. water, alcohol, and ether.

Amide of the ethyl ether $NH_2.CS.CO_2Et$. Mol. w. 133. [64°]. Formed in like manner. Lemon-yellow crystals. Re-converted by boiling with alcohol and $Pb(OH)_2$ into cyanoformic ether. Methylamine and ethylamine form the crystalline compounds $CO(NHMe).CS.NH_2$ and $CO(NHEt).CS.NH_2$ respectively.

Amide of the isobutyl ether $NH_2.CS.CO_2C_4H_9$. [58°]. Lemon-yellow crystals, sl. sol. water.

Di-amide $CO(NH_2).CS.NH_2$. Formed from $CO_2Et.CS.NH_2$ and alcoholic ammonia (Weddige, *J. pr.* [2] 9, 137). Lemon-yellow needles (from alcohol), sl. sol. water.

Di-thio-oxalic acid. *Amide* $CS(NH_2).CS(NH_2)$. *Hydrogen rubeanide.* Mol. w. 120. Formed, together with yellow $Cy.CS.NH_2$, by combination of cyanogen with H_2S (Wöhler, *P.* 3, 177; Völckel, *A.* 38, 315). Formed also by passing cyanogen into an alcoholic solution of NaSH and ppg. by HCl (Wollner, *J. pr.* [2] 29, 129; Ephraim, *B.* 22, 2305). Prepared by passing H_2S into an ammoniacal solution of $CuSO_4$ which has been decolourised by KCy (Formánek, *B.* 22, 2655). Small yellowish-red crystals, sl. sol. water, sol. alcohol and ether. Dilute KOHAq forms oxalic acid, conc. KOHAq forms KCy and KCyS. Boiling HClAq forms oxalic acid. MeI and MeOH at 150° form SMe_3I. Alcoholic hydroxylamine hydrochloride (2 mols.) forms $C_2(NH_2)_2(NOH)_2$ and H_2S. Benzoic aldehyde, acting on a boiling solution, forms a compound [209°] which is apparently $\mathrm{CHPh}{<}\genfrac{}{}{0pt}{}{\mathrm{S}}{\mathrm{N}}{\geqslant}\mathrm{C.C}{\leqslant}\genfrac{}{}{0pt}{}{\mathrm{S}}{\mathrm{N}}{>}\mathrm{CHPh}$ (Ephraim, *B.* 24, 1027).—$PbC_2H_2N_2S_2$: orange pp. (Wallach, *B.* 13, 528). Yields PbS on boiling with water.

Anilide CS(NHPh).CS(NHPh). [133°]. Formed from oxanilide by successive treatment with PCl_5 and H_2S (Wallach, *B.* 13, 527). Golden plates.

Di-methyl-di-amide CS(NHMe).CS(NHMe). [140°]. Formed from thiocyanic acid, alcohol, and methylamine (Wallach, *A.* 262, 360). Yellow crystals, sl. sol. alcohol. Converted by NaOEt and propyl chloride into $C(NMe)(SC_3H_7).C(NMe)(SC_3H_7)$ (170°–175°).

Di-ethyl-di-amide CS(NHEt).CS(NHEt). [58°]. Formed in like manner. Yellowish-red crystals, insol. water. Converted by NaOEt and EtI into C(NEt)(SEt).C(NEt)(SEt) (126°–129°).

Di-amyl-di-amide $CS(NHC_5H_{10}).CS(NHC_5H_{10})$. [60°]. Formed from thiocyanic acid, alcohol, and amylamine (Wallach, *A.* 262, 362). Red prisms.

Di-benzyl-diamide $CS(NHCH_2Ph).CS(NHCH_2Ph)$. [115°]. Formed from thiocyanic acid, alcohol, and benzylamine. Yellowish-red crystals, sl. sol. warm alcohol.

Hexa-thio-ortho-oxalic acid. *Ethyl ether* $C_2(SEt)_6$. Formed from C_2Cl_6 and NaSEt (Claesson, *J. pr.* [2] 15, 212). Heavy oil.

THIO-OXY- *v.* SULPHYDRO-.

THIO-PARABANIC ACID. *Methyl derivative v.* METHYL-THIO-PARABANIC ACID.

Allyl derivative $C_6H_6N_2SO_2$ *i.e.*  $CS{<}{\genfrac{}{}{0pt}{}{NH.CO}{N(C_3H_5)}}{>}CO$. *Oxalyl-thio-sinamine.* [90°]. Formed by warming the dicyanide of allyl-thio-urea with dilute H_2SO_4 (Maly, *Z.* 1869, 260). Lemon-yellow needles, m. sol. cold water.

THIOPHENE C_4H_4S *i.e.*  $S{<}{\genfrac{}{}{0pt}{}{CH:CH}{CH:CH}}$ (84° cor.). V.D. 3·0 (calc. 2·9). S.G. ^{23} 1·062; $\frac{4}{0}$ 1·0884; $\frac{15}{4}$ 1·0705 (R. Schiff, *B.* 18, 1601). S.V. 84·9. R_∞ 41·4 (Nasini a. Scala, *G.* 17, 70). H.C.p. 670,900 (Berthelot a. Matignon, *C. R.* 111, 10; *Bl.* [3] 4, 252). H.F. –14900. *Critical temperature* 317° (Pawlewski, *B.* 21, 2141). *Critical pressure* 47·7 atmospheres. Occurs in coal-tar benzene to the extent of about ·5 p.c. (V. Meyer, *B.* 16, 1471).

Formation.—1. In small quantity by passing acetylene through boiling sulphur (V. Meyer a. Sandmeyer, *B.* 16, 2176).—2. By heating succinic anhydride with P_2S_5.—3. By heating sodium succinate with P_2S_3, the yield being 50 p.c. of the theoretical amount (Volhard a. Erdmann, *B.* 18, 454). It is not formed by heating *s*-di-bromo-succinic acid with P_2S_3 or P_2S_5 (Ossipoff, *J. R.* 20, 245).—4. By heating erythrite with P_2S_5 (Paal a. Tafel, *B.* 18, 688).—5. From its (*α*)-carboxylic acid, which is obtained by heating mucic acid with BaS (Paal a. Tafel, *B.* 18, 456).—6. In small quantities by passing Et_2S through a red-hot tube (Meyer, *B.* 18, 217).—7. In small quantities by passing ethylene, coal-gas, or ligroïn-vapour over heated iron pyrites.—8. In small quantities by heating P_2S_5 with crotonic acid, with *n*-butyric acid, with paraldehyde, or with ether (Meyer).

Isolation.—20 pts. commercial 'pure' benzene is shaken for four hours with 1 pt. of H_2SO_4. The acid is diluted with two or three times its weight of water and treated at once with steam. Nearly pure thiophene passes over. Yield, about 3½ p.c. by volume of the H_2SO_4 used (Schulze, *B.* 18, 497).

Properties.—Liquid with faint odour, not decomposed below 335°. Not solid at –20°. Greatly resembles benzene. Oxidised by HNO_3 with great violence. On shaking with isatin and H_2SO_4 it yields a blue colouring matter (indophenine). Not affected by boiling with sodium. Benzene that contains thiophene gives a bright-blue colour to H_2SO_4 containing nitrous acid. Thiophene (10 g.) shaken with alcohol (100 g.), cold saturated $HgCl_2$ solution (1,000 g.), and NaOAc (70 g.) dissolved in water (130 g.) forms a white pp. containing $C_4H_3(HgCl)S$, which crystallises from alcohol in white plates [183°], and $C_4H_2(HgCl)_2S$, a white powder, insol. alcohol (Volhard, *A.* 267, 172). The compound $C_4H_3(HgCl)S$ is converted by AcCl into *α*-thienyl methyl ketone and by I into di-iodo-thiophene. Thiophene combines with $CHPh_3$ and with di-bromo-di-(*β*)-naphthyl oxide (Liebermann, *B.* 26, 853).

Reactions.—1. *Chloral* and H_2SO_4 yield $CCl_3.CH(C_4H_3S)_2$.—2. BzCl and $AlCl_3$ form thienyl phenyl ketone.—3. *Phenyl-glyoxylic acid* and H_2SO_4 form $C_{12}H_8NSO_2$, which dissolves in chloroform with crimson, and in H_2SO_4 with purple colour.—4. Cl and Br yield chloro- and bromo- derivatives.—5. H_2SO_4 forms a brown solution containing a sulphonic acid, and slowly decomposes the thiophene, forming H_2S, SO_2 and an amorphous pp.—6. H_2SO_4 and KNO_2 form a compound called 'nitroso-dithiophene'  $HO.N{<}{\genfrac{}{}{0pt}{}{C_4H_2S}{C_4H_2S}}{>}O$ (?), ppd. by water as a dark insoluble powder (Liebermann, *B.* 20, 3231).—7. Passed with PCl_3 through a red-hot tube it forms $C_4H_3S.PCl_2$ (218°) which is decomposed by water into $C_4H_3S.P(OH)_2$ [70°] and is converted by Cl into $C_4H_3S.PCl_4$, which is converted by SO_2 into $C_4H_3S.POCl_2$ (259°) and by water into $C_4H_3S.PO(OH)_2$ [159°] (Sachs, *B.* 25, 1514).—8. *Diazobenzene chloride* and $AlCl_3$ forms (*β*)-phenyl-thiophene [57°] (Möhlau a. Berger, *B.* 26, 2001).

THIOPHENE (*α*)-CARBOXYLIC ACID

$C_5H_4SO_2$ *i.e.*  $S{<}{\genfrac{}{}{0pt}{}{CH\!-\!\!-\!\!-\!CH}{C(CO_2H):CH}}$ *Thiophene 'β'-carboxylic acid.* [126·5°]. (260° cor.). H.F. 85,400. H.C.p. 591,900 (Stohmann, *J. pr.* [2] 43, 12). Formed by adding sodium-amalgam to a mixture of $Cl.CO_2Et$ with (*α*)-iodothiophene, with di-iodo-thiophene, or with di-bromo-thiophene (Nahnsen, *B.* 17, 2192; 18, 2304; Bonz, *B.* 18, 2306). Formed also by heating mucic acid with BaS for 6 hours at 205°, the yield being 12 p.c. of the theoretical (Paal a. Tafel, *B.* 18, 456). Obtained by oxidation of (*α*)-ethyl-thiophene (Schleicher, *B.* 18, 3017), of (*α*)-propyl-thiophene (Ruffi, *B.* 20, 1740), of thienyl methyl ketone (Peter, *B.* 17, 2645; 18, 542), and of thienyl ethyl ketone (Ernst, *B.* 20, 518) with alkaline $KMnO_4$.

Properties.—Slender white needles (from water) or long flat needles (by sublimation), v. sol. hot water, sl. sol. cold, v. e. sol. alcohol and ether, m. sol. chloroform, sl. sol. ligroin. Gives a blue colour on warming with isatin and H_2SO_4 (indophenine reaction). Yields thiophene on distilling with lime. Yields a di-bromo- derivative [211°].

Salts.—BaA'_2 2aq. Small crystals. S. 22·19 at 14·5°.—CaA'_2 3aq. S. 18·5 at 18·5°.—ZnA'_2 (dried). S. 14 at 15°.—PbA'_2 (dried) ·5 at 18·5°.—AgA': plates or needles. S. ·195 at 11°.

Ethyl ether EtA'. (218° cor.). S.G. ^{22} 1·1155. Liquid, smelling like benzoic ether.

Chloride $C_4H_3S.COCl$. (190° uncor.). Liquid, smelling like benzoyl chloride.

Amide $C_4H_3S.CONH_2$. [174°] (Meyer, *A.* 236, 210). Prisms, m. sol. ether. Phenyl thiocarbimide forms $C_4H_3S.CO.NH.CO.NHPh$. [206°]

Anilide $C_4H_3S.CONHPh$. [140°]. Formed by the action of phenyl cyanate on thiophene in presence of $AlCl_3$ (Leuchart a. Schmidt, *B.* 18, 2340). Iridescent plates.

Amidoxim $C_4H_3S.C(NOH).NH_2$. [92°]. Formed by the action of hydroxylamine on the nitrile (Meyer, *A.* 236, 213). Long prisms (from benzene).

Nitrile (192°) (D.); (200° cor.) (Peter, *B.* 18, 543). Formed by distilling thienyl-glyoxylic acid with aqueous hydroxylamine (Douglas, *B.* 25, 1311).

Tetrahydride

$S\left\langle\begin{matrix}\mathrm{CH(CO_2H).CH_2}\\ \mathrm{CH_2{-\!-\!-}CH_2}\end{matrix}\right.$ [51°]. H.F. 114,900. H.C.p. 700,400. Formed by reducing the acid, in alkaline solution, with sodium-amalgam (Ernst, *B.* 19, 3278; 20, 518). Plates or needles (from ligroin), v. e. sol. water and alcohol, v. sol. ether. Volatile with steam. Much decomposed on distillation. Reduces ammoniacal $AgNO_3$. Salts.—CaA'_2 3aq. Crystalline, sol. water. — AgA'. M. sol. water. *Methyl ether* MeA'. (c. 206°). *Ethyl ether* EtA'. Liquid.

Thiophene (β)-carboxylic acid

$S\left\langle\begin{matrix}\mathrm{CH{:}CH}\\ \mathrm{CH{:}C.CO_2H}\end{matrix}\right.$ (γ)-*Thiophenic acid.* [136°]. S. ·44 at 17°. Formed by the action of alkaline $KMnO_4$ on (β)-methyl-thiophene (Muhlert, *B.* 18, 3008) or (β)-ethyl-thiophene, the yield being about 8 p.c. (Damsky, *B.* 19, 3284). Needles (from water), sol. ether, votatile with steam. Gives the indophenine reaction.—CaA'_2 ½aq. S. (of CaA'_2) 7·92 at 14·5°.—BaA'_2 (dried). S. 11·54 at 17°.—AgA'. Needles or plates, v. sl. sol. Aq.

Amide $C_4H_3S.CONH_2$. [178°]. Converted by phenyl cyanate into $C_4H_3S.CO.NH.CO.NHPh$. [206°].

Thiophene 'α'-carboxylic acid. [118°]. (258° cor.). This is a mixture of the (α)- and (β)- acids. It is got by saponifying the mixed nitrile which is formed by distilling a mixture of potassium thiophene (α) and (β) sulphonates with KCy (V. Meyer, *B.* 16, 2174; 18, 2315; Bonz, *B.* 18, 2308). Formed also by oxidising a mixture of (α)-methyl-thiophene (2 pts.) and (β) methyl-thiophene (3 pts.) and by slow evaporation of an aqueous solution of the mixed thiophene carboxylic acids in the cold (Egli, *B.* 18, 548; V. Meyer, *B.* 19, 2891; *A.* 236, 221). Volatile with steam. Can be separated into the (α)- and (β)- acids by crystallisation.

Thiophene dicarboxylic acid

$S\left\langle\begin{matrix}\mathrm{CH{=\!=\!=}CH}\\ \mathrm{C(CO_2H){:}C(CO_2H)}\end{matrix}\right.$ [270°]. Formed by oxidising the corresponding di-methyl-thiophene with alkaline $KMnO_4$ (Grünewald, *B.* 20, 2586). Formed also by oxidising (β)-methyl-thienyl methyl ketone (Gerlach, *A.* 267, 153). Long needles (from water), v. e. sol. ether. Not volatile with steam. Resorcin at 200° forms a fluorescein which exhibits yellowish-green fluorescence in alkaline solution.—PbA''.—BaA''. Crystals, sl. sol. cold water.—Ag_2A''. White pp.

Methyl ether Me_2A''. [59·5°]. Plates.

Thiophene dicarboxylic acid

$S\left\langle\begin{matrix}\mathrm{C(CO_2H){:}CH}\\ \mathrm{C(CO_2H){:}CH}\end{matrix}\right.$

Formation.—1. By oxidation by alkaline $KMnO_4$ of di-methyl-thiophene from coal tar (Messinger, *B.* 18, 567), from (α)-ethyl-thienyl methyl ketone, from (α)-ethyl-thiophene (α)-carboxylic acid (Schleicher, *B.* 18, 3020), from methyl-thienyl methyl ketone (Demuth, *B.* 18, 3025), and from (α)-methyl-thiophene carboxylic acid (Levi, *B.* 19, 656).—2. By saponifying its nitrile, which may be got by fusing potassium thiophene disulphonate with KCy (Jaekel, *B.* 19, 191).—3. By saponifying its ether which is got by the action of sodium-amalgam on a mixture of di-bromo-thiophene and $ClCO_2Et$ (Bonz, *B.* 18, 2306).

Properties.—Crystalline powder, v. sl. sol. cold water, sol. ether. Not melted at 300°. Does not give the fluoresceïn reaction.

Salts. — BaA'' aq. Crystalline, v. sl. sol. cold water.—CaA'' 3aq.—Ag_2A'': white pp.

Methyl ether Me_2A''. [145°] (J.); [147°] (S.); [151°] (D.). White needles from alcohol.

Ethyl ether Et_2A''. [47°] (J.); [52°] (S.). Long needles (from alcohol).

Nitrile $C_4H_2SCy_2$. [92°]. Crystals.

Tetrahydride

$S\left\langle\begin{matrix}\mathrm{CH(CO_2H).CH_2}\\ \mathrm{CH(CO_2H).CH_2}\end{matrix}\right.$ [162° cor.]. Formed by reducing the acid in alkaline solution by sodium-amalgam (Ernst, *B.* 19, 3275). Plates, v. sol. water, sol. ether. Reduces hot ammoniacal $AgNO_3$. Hot conc. H_2SO_4 evolves CO (1 mol.).—BaA'': scales.—Ag_2A'': white powder.—Me_2A''. Oil.

Thiophene dicarboxylic acid

$S\left\langle\begin{matrix}\mathrm{CH{=\!=\!=}C.CO_2H}\\ \mathrm{C(CO_2H){:}CH}\end{matrix}\right.$. Formed by oxidation of the corresponding di-methyl-thiophene by alkaline $KMnO_4$ (Zelinsky, *B.* 20, 2022). Needles, sl. sol. cold water. Decomposes and partially sublimes at 280°, v. sol. hot water.—Ag_2A''.

Methyl ether Me_2A''. [121°]. Plates.

Ethyl ether Et_2A''. [36°].

Thiophene tri-carboxylic acid $C_4SH(CO_2H)_3$. Formed by oxidation of di-methyl-thienyl methyl ketone with $KMnO_4$ (Messinger, *B.* 18, 2302).

Methyl ether Me_3A'''. [118°] Plates, v. sol. alcohol and ether.

References.—Bromo- and Iodo- THIOPHENE CARBOXYLIC ACID and Nitro-THIOPHENIC ACID.

THIOPHENE GREEN $C_{21}H_{22}N_2S$. The leuco-base $C_4SH_3.CH(OH)(C_6H_4NMe_2)_2$ is got by heating thiophenic aldehyde with di-methyl aniline, $ZnCl_2$, and a little alcohol at 100° (Levi, *B.* 20, 513). It crystallises in needles [93°], and is readily oxidised to thiophene green $C_4SH_3.C(OH)(C_6H_4NMe_2)_2$, which is an oil and forms the salts $(C_{21}H_{22}N_2S)_3ZnCl_2$ 2aq, $B'H_2SO_4$, $B'_2 3H_2C_2O_4$ 2aq, and $B'2C_6H_3N_3O_7$, crystallising in scales with coppery lustre.

Leuco-thiophene green *v.* TETRA-METHYL-DI-AMIDO-DI-PHENYL-THIENYL-METHANE.

THIOPHENE (α)-SULPHINIC ACID $C_4H_3S.SO_2H$. [67°]. Formed by the action of zinc-dust on an alcoholic solution of thiophene sulphonic chloride (Weitz, *B.* 17, 800). Needles, v. sol. water, alcohol, and ether. Gives the indophenine reaction.—BaA'_2 2aq. White plates, v. sol. water.—ZnA'_2 3aq.—AgA'. Crystalline pp.

THIOPHENE 'α'-SULPHONIC ACID $C_4H_3S.SO_3H$. Formed by shaking thiophene (20 g.) dissolved in ligroïn (2,000 c.c.) with H_2SO_4 (300 c.c.) for 2 hours (V. Meyer a. Kreis, *B.* 16, 2172; Biedermann, *B.* 19, 1615). Deliquescent mass. Yields thiophene on distillation. It is doubtless a mixture of the (α) and (β) acids. —NaA'aq.—BaA'_2 3aq.—CaA'_2.—PbA'_2 aq. Very soluble powder.—AgA' 3aq. Plates (Weitz, *B.* 17, 796).

Ethyl ether EtA'. Oil.

Chloride $C_4H_3S.SO_2Cl$. [28°]. (above 200°). Oil or colourless crystals.

Amide $C_4H_3S.CONH_2$. [142°] (Langer, *B.* 17, 1568). Needles (from water).—$C_4H_3S.CO.NHAg$. Pearly scales.

Anilide $C_4H_3S.CONHPh$. [96°].

Thiophene (β)-sulphonic acid  $S<\begin{matrix}CH:CH\\CH:C.SO_3H\end{matrix}$. Formed by the action of sodium-amalgam on di-bromo-thiophene (β)-sulphonic acid, which is got by sulphonation of di-bromo-thiophene (Langer, *B.* 17, 1567; 18, 553). Obtained in like manner from iodo-thiophene sulphonic acid, and from tri-bromo-thiophene sulphonic acid (Rosenberg, *B.* 18, 1776). Crystalline solid, v. sol. water. Gives a blue colour with isatin and H_2SO_4.—BaA'_2.

Chloride $C_4H_3S.SO_2Cl$. [43°]. Plates, v. sol. ether, insol. ligroïn.

Amide $C_4H_3S.SO_2NH_2$. [148°]. Tables.

Thiophene disulphonic acid $C_4H_2S(SO_3H)_2$. Formed by reduction of di-bromo-thiophene 'β'-di-sulphonic acid by sodium-amalgam (Langer, *B.* 18, 554, 1114; Rosenberg, *B.* 18, 3030). Crystalline, v. sol. water.—$BaA''2\frac{1}{2}aq$.

Chloride $C_4H_2S(SO_2Cl)_2$. [149°]. Scales.

Amide $C_4H_2S(SO_2NH_2)_2$. [c. 280°]. Needles.

Thiophene disulphonic acid $C_4H_2S(SO_3H)_2$. Formed by reducing iodo-thiophene (αβ)-di-sulphonic acid with sodium-amalgam (Langer, *B.* 18, 560).

Amide $C_4H_2S(SO_2NH_2)_2$. [142°]. Plates. Gives the indophenine reaction.

Thiophene disulphonic acid $C_4H_2S(SO_3H)_2$. Formed from lead thiophene sulphonate and fuming H_2SO_4 (Jaekel, *B.* 19, 185, 1066). Crystalline, v. sol. water and alcohol.—$K_2A''aq$: prisms, v. sol. water.—$Na_2A''3aq$. Needles, v. sol. water.—$BaA''3aq$. Flat prisms, sl. sol. water.—$CuA''4aq$. Blue needles.—Ag_2A''.

Chloride $C_4H_2S(SO_2Cl)_2$. [77·5°]. Needles (from ether).

Amide $C_4H_2S(SO_2NH_2)_2$. [211·5].

References.—Di-bromo-, Iodo- and Nitro-thiophene sulphonic acid.

THIOPHENIC ACID *v.* Thiophene carboxylic acid.

THIOPHENIC ALDEHYDE $C_4H_3S.CHO$. (198° cor.). S.G. ²¹ 1·215. Formed by distilling (α)-thienyl-glyoxylic acid (Biedermann, *B.* 19, 637, 1853). Formed also by the action of H_2S on  $CHCl<\begin{matrix}CH_2.CH_2\\CO\ .CO\end{matrix}$ (Hantzsch, *B.* 22, 2838). Oil, smelling like benzoic aldehyde. Oxidised by air to thiophene (α)-carboxylic acid.

Oxim $C_4H_3S.CH(NOH)$. *Thiophene synaldoxim.* [128°]. Needles (from ether). Converted by NaOHAq into thiophene carboxylic nitrile (Hantzsch, *B.* 24, 47). Yields an acetyl-derivative [75°-80°]. NaOMe and MeI in MeOH yield  $C_4SH_3.CH<\begin{matrix}NMe\\O\end{matrix}$ [120°], crystallising in tables; converted by dilute H_2SO_4 into the aldehyde and (β)-methyl-hydroxylamine (Goldschmidt a. Zanoli, *B.* 25, 2588). Phenyl cyanate in ether forms $C_4SH_3.CH:NO.CO.NHPh$ [70°], crystallising in needles.

Oxim $C_4H_3S.CH:NOH$. *Thiophene anti-aldoxim.* Formed by the action of hydroxylamine hydrochloride, NaOHAq and Na_2CO_3 on the aldehyde (Goldschmidt a. Zanoli, *B.* 25, 2590). Converted by phenyl cyanate into $C_4SH_3.CH:NO.CO.NHPh$ [144°], whence NaOH forms $C_4SH_3.CH:N.NHPh$ [46°]. *o*-Tolyl cyanate forms $C_4H_3S.CH:NO.CO.NH.C_7H_7$ [66°].

Phenyl hydrazide $C_4SH_3.CH:N_2HPh$. [134·5°]. Needles (from alcohol).

THIOPHENIC IMIDO-ETHYL ETHER $C_4H_3S.C(OEt):NH$. The salt B'HCl is formed by the action of dry HCl on the nitrile of thiophene carboxylic acid (Douglas, *B.* 25, 1312). It is crystalline, and is converted by hydroxylamine into $C_4H_3S.C(OEt):NOH$ [67°].

THIOPHENINE is Amido-thiophene.

THIOPHENOL *v.* Phenyl mercaptan.

THIOPHENURIC ACID $C_7H_7NSO_3$. [172°]. Excreted in the urine of rabbits after injection of sodium thiophene (α)-carboxylic acid (Jaffé a. Levi, *B.* 21, 3458). Prisms, resembling hippuric acid (from water), v. sl. sol. ether, v. sol. alcohol. Split up by boiling baryta-water into glycocoll and thiophene (α)-carboxylic acid.—$BaA'_2 2aq$. Needles, v. sol. water.—$CaA'_2 xaq$.—AgA'.

THIO-PHENYL-ACETIC ACID. *Amide* $C_6H_5.CH_2.CS.NH_2$. [98°]. Formed by heating phenyl-acetamide (3 pts.) with P_2S_5 (2 pts.), and also by allowing a solution of phenyl-acetonitrile in alcoholic ammonium sulphide to stand for some days (Bernthsen, *B.* 11, 503; *A.* 184, 292). Trimetric crystals (from alcohol), decomposed on distillation into H_2S and $C_6H_5.CH_2.CN$.

Reactions.—1. Boiling NH_3Aq forms phenyl-acetamide.—2. HgO forms phenyl-acetonitrile.—3. Zn and HClAq form phenyl-ethyl-amine (Colombo a. Spica, *B.* 8, 821).—4. *Benzoic aldehyde* forms oily $C_{23}H_{20}N_2S_2$ (?)—5. *Sodium-amalgam* forms $Ph.CH_2.CH_2NH_2$ and a compound $C_{24}H_{27}NS_2$ [108°].—6. *Iodine* added to a hot alcoholic solution forms $C_{16}H_{14}N_2S$ [42°].—7. MeI forms $(CH_2Ph.C(NH).SMe)HI$ [139°], which gives rise to $(C_9H_{11}NS)_2H_2PtCl_6$.—8. EtI forms $(C_{10}H_{13}NS)HI$ [116°], which is v. e. sol. water, and yields, on treatment with NaOHAq, the free base $CH_2Ph.C(NH).SEt$, which is an oil that quickly decomposes into mercaptan and phenyl-acetonitrile. The salts $(C_{10}H_{13}NS)HCl$ [c. 120°], $B'_2H_2PtCl_6$ [below 130°], and B'HBr are crystalline.—9. *Aniline* forms the compound $CH_2Ph.C(NH_2):NPh$.

THIO-PHENYL-ALLOPHANIC ACID *v.* Phenyl-thio-allophanic acid.

THIO-DI-PHENYL-AMINE *v.* Imido-di-phenyl sulphide.

THIO-PHENYL-CARBAMIC ACID *v.* Phenyl-thio-carbamic acid.

THIO-DI-PHENYL KETONE *v.* Thio-benzophenone.

THIO-DI-PHENYL-METHYL-AMINE *v.* Methyl-imido-di-phenyl sulphide.

DI-THIO-PHTHALIC ACID $C_6H_4(CO.SH)_2$. The salt K_2A'' is formed by dissolving KSH (2 mols.) in an alcoholic solution of phenyl phthalate (1 mol.). The free acid splits up at once into H_2S and thiophthalic anhydride (Schreder, *B.* 7, 706).

(α)-Di-thio-isophthalic acid. The K salt, formed by the action of KSH on phenyl isophthalate, crystallises in yellow needles.

Ethyl ether Et_2A''. Formed by adding water to the hydrochloride of $C_6H_4(C(NH).SEt)_2$ (Luckenbach, *B.* 17, 1435). Small needles.

(β)-Di-thio-isophthalic acid. *Amide* $C_6H_4(CSNH_2)_2$. [200°]. Formed by heating isophthalic nitrile with alcoholic ammonium

sulphide (L.). Needles, sol. hot alcohol. Reconverted into the nitrile by lead acetate. Boiling KOHAq forms isophthalic acid.

THIO-PHTHALIC ANHYDRIDE $C_8H_4SO_2$ *i.e.* $C_6H_4<\begin{smallmatrix}CO\\CO\end{smallmatrix}>S$. [114°]. (284°). Formed by the action of KSH on phthalyl chloride, or on phenyl phthalate (Graebe a. Zschokke, *B.* 17, 1175). Formed also by the action of As_2S_3 on phthalyl chloride (Rayman, *Bl.* [2] 47, 898). Plates, v. sol. hot alcohol, ether, and chloroform, sl. sol. water. Volatile with steam. Sol. alkalis and converted by long boiling with alkalis into phthalic acid. Ammonia forms phthalimide. Resorcin and H_2SO_4 give a thiofluoresceïn, the alkaline solution of which is deep red with green fluorescence.

THIO-PHTHALIDE $C_6H_4<\begin{smallmatrix}CO\\CO\end{smallmatrix}>S$. [57°]. Formed by heating $C_6H_4Cy.CH_2.SCy$ with conc. HClAq for 5 hours at 180° (Day a. Gabriel, *B.* 23, 2480). Thin needles (from dilute alcohol).

THIO-PHTHALIMIDINE C_8H_7NS *i.e.* $C_6H_4<\begin{smallmatrix}C(NH)\\CH_2\end{smallmatrix}>S$ or $C_6H_4Cy.CH_2SH$. [62°]. Formed by warming *o*-cyano-benzyl sulphocyanide with H_2SO_4 at 65° (Day a. Gabriel, *B.* 23, 2481). Formed also by adding KSHAq to *o*-cyano-benzyl chloride in alcohol. Needles, which darken in air, v. sol. alcohol and ether. Boiling NaOHAq forms thiophthalide. KSH added to its alcoholic solution forms $C_{16}H_{10}S_3$, crystallising from nitrobenzene in needles with green lustre.—B'HCl. Needles.—$B'_2H_2PtCl_6$. Orange-yellow prisms.—B'HI. Needles.—**Picrate**: slender needles.

THIOPHTHENE $C_6H_4S_2$ *i.e.* $\begin{smallmatrix}CH{-}C{-}CH.\\CH.S.C.S.CH\end{smallmatrix}$ (225° cor.). Formed by distilling citric acid (1 pt.) with P_2S_3 (2 pts.), adding NaOHAq, and distilling with steam (Biedermann a. Jacobson, *B.* 19, 2444). Oil, not solid at −10°. Gives the indophenine reaction.—$B'C_6H_3N_3O_7$. [133°]. Yellow needles, v. sol. alcohol and benzene.

Reference.—TETRA-BROMO-THIOPHTHENE.

THIOPHYLLINE $C_7H_8N_4O_2$. [264°]. Occurs, in small quantity, in extract of tea (Kossel, *B.* 21, 2164). Crystals (containing aq), more sol. water and alcohol than theobromine, v. sol. NH_3Aq. Forms salts with acids. On evaporation with chlorine-water it leaves a scarlet residue, turned violet by NH_3Aq.—$C_7H_7AgN_4O_2$. Amorphous, converted by MeI into caffeïne $C_7H_7MeN_4O_2$ [229°].

(*a*)-**THIO-PROPIONIC ACID** C_3H_6OS. *Methyl ether* $CH_3.CH_2.CO.SMe$. (120°). V.D. 51·23. Formed from propionyl chloride and lead mercaptide in the cold (Obermeyer, *B.* 20, 2922).

(β)-Thio-propionic acid Et.CS.OH. The salt NaA'aq formed by boiling propionitrile with alcoholic ammonium sulphide is crystalline (Dupré, *Bl.* [2] 29, 304).

Amide EtC(NH).SH. [42°]. Formed by heating propionamide (5 mols.) with P_2S_5 (1 mol.) in benzene for a short time (Hubacher, *A.* 259, 229). Yellowish plates, v. e. sol. benzene.

THIO-ISOPROPYL-COUMARIN $C_{12}H_{12}SO$ *i.e.* $C_6H_4<\begin{smallmatrix}CH:C(C_3H_7)\\O{-}CS\end{smallmatrix}$. [81°]. Formed by heating isopropyl-coumarin with P_2S_5 at 120° (Aldringen, *B.* 24, 3463). Reddish-yellow needles, sol. hot alcohol, sl. sol. ether.

THIO-PRUSSIAMIC ACIDS. By heating ammonium sulphocyanide there is formed, besides thio-urea, dithiodiprussiamic acid $C_6H_7N_9S_2$, a yellowish-white powder, sl. sol. hot water; thiodiprussiamic acid $C_6H_8N_{10}S$, amorphous, m. sol. hot water; and ammonium dithiotriprussiamate $C_9H_{13}N_{15}S_2$, which crystallises from water. The first acid gives no colour with $FeCl_3$, the two other bodies give a red colour. The lead salts of these acids dissolve in hot water.

THIOTETRAPYRIDINE, so called, $C_{20}H_{18}N_4S$ (?). [155°]. Formed by heating nicotine (1 pt.) with sulphur (6 pts.) at 150° till the mass is chrome-green (Cahours a. Etard, *Bl.* [2] 34, 452). Yellow prisms (from alcohol).—B'2HCl.—$B'HHgCl_3$.—$B'H_2PtCl_6$: yellow amorphous pp.

THIO-PYROCATECHIN *v.* OXY-PHENYL MERCAPTAN.

THIO-PYROMUCIC ACID. *Amide* $C_4H_3O.CS.NH_2$. [127°]. Formed by passing H_2S into a solution of furfuronitrile in alcohol-ether (Douglas, *B.* 25, 1314). Yellowish crystals, sl. sol. cold water, v. sol. alcohol.

THIO-PYRUVIC ACID. The compound $(C_3H_4O_2S)C_3H_4O_3$ [87°] separates as a powder when H_2S is passed into pyruvic acid (Böttinger, *A.* 188, 325). It is v. e. sol. water and is converted by boiling HIAq into $CH_3.CH(SH).CO_2H$. Boiling water forms H_2S and thiopyruvic acid.

DI-THIO-RESORCIN $C_6H_4(SH)_2$. Mol. w. 142. [27°]. (243°). Formed by reducing the sulphochloride $C_6H_4(SO_2Cl)_2$ with tin and HClAq (Patschke, *J. pr.* [2] 2, 418, Körner, *G.* 6, 140). Crystals, smelling like some geraniums. $Pb(OAc)_2$ added to its alcoholic solution ppts. orange $C_6H_4S_2Pb$, whence MeI forms $C_6H_4(SMe)_2$ (278°) (Obermeyer, *B.* 20, 2927).

THIO-RUFIC ACID $C_{10}H_{11}S_3O_4$. Formed by the action of CS_2 on a mixture of NaOEt and acetoacetic ether (Norton a. Oppenheim, *B.* 10, 701). Pearly orange scales, nearly insol. water.—NaA': brick-red needles.—CaA'_2: red needles.

THIO SALICYLIC ACID *v.* OXY-THIO-BENZOIC ACID.

THIOSINAMINE *v.* ALLYL-THIO-UREA.

THIO-SUCCINIC ACID. *Anhydride* $C_2H_4<\begin{smallmatrix}CO\\CS\end{smallmatrix}>O$. '*Sulphosuccinyl.*' [31°]. (225°). Formed by adding succinyl chloride dissolved in benzene or CS_2 to an aqueous solution of Na_2S. Got also by distilling succinic acid (100 g.) with P_2S_5 (100 g.) (Auger, *A. Ch.* [6] 22, 333). White crystals. Its aqueous solution gives off H_2S on heating. Phenyl-hydrazine forms $CO_2H.C_2H_4.C(SH){:}N.NHPh$ [120°] and $C_2H_4<\begin{smallmatrix}CO\\C(N_2HPh)\end{smallmatrix}>O$ [216°], which on distillation changes to succinyl-phenyl-hydrazine [155°]. Phenyl-hydrazine also produces $C_2H_4(CO.N_2H_2Ph)_2$ [219°] (Zanetti, *C. C.* 1889, 668). Sodium-amalgam forms $C_4H_5NaSO_2$, converted by phenyl-hydrazine acetate into $CO_2H.C_2H_4.CH{:}N_2HPh$ [c. 175°].

Di-thio-succinic acid $C_2H_4(CO.SH)_2$. The salt K_2A'', got by boiling succinyl-phenol with KSH in alcohol, crystallises in minute needles, v. sol. water, alcohol, and ether (Weselsky, *B.* 2, 518). Its aqueous solution is decomposed by spontaneous evaporation. Acids split it up into H_2S and thiosuccinic anhydride (*v. supra*).

Ethyl ether $C_2H_4(CO.SEt)_2$. (271°). Formed from di-phenyl succinate (42 g.) and sodium mercaptide (30 g.) in dry ether in the cold (Seiffert, *J. pr.* [2] 31, 469). Oil, smelling of garlic.

THIO-SUCCINURIC ACID $C_5H_8N_2SO_3$. [211°]. Formed by heating succinic anhydride with thio-urea at 140° (Pike, *B.* 6, 1105). Yellowish powder, insol. alcohol and ether, sl. sol. water and HOAc. Decomposed by alkalis into thio-urea and succinic acid.

(α) - DI - THIO - TEREPHTHALIC ACID $C_8H_6S_2O_2$ *i.e.* $C_6H_4(CO.SH)_2$. Formed by the action of alcoholic KSH on di-phenyl terephthalate (Schreder, *B.* 7, 708). Amorphous, v. sl. sol. alcohol.

(β) - Di - thio - terephthalic acid. *Amide* $C_6H_4(CS.NH_2)_2$. [263°]. Formed by heating terephthalic nitrile with alcoholic ammonium sulphide (Luckenbach, *B.* 17, 1430). Yellow amorphous powder, insol. alcohol. Boiling with lead acetate reproduces the nitrile.

THIOSULPHATES. Salts of the hypothetical *thiosulphuric acid* $H_2S_2O_3$. These salts were called *hyposulphites* before the isolation of the true hyposulphites ($M_2S_2O_4$, p. 592). $Na_2S_2O_3.5aq$ is still, however, commonly known as sodium hyposulphite. Thiosulphates are formed by boiling normal alkali sulphites in solution with S; ($M_2SO_3Aq + S = M_2S_2O_3Aq$); caustic alkali solutions and milk of lime also give thiosulphates by boiling with S. Thiosulphates are produced by the action of air, SO_2, or $K_2Cr_2O_7Aq$ on the alkali and alkaline earth polysulphides in solution ($M_2S_5Aq + 3O = M_2S_2O_3Aq + 3S$; $2M_2S_5Aq + 3SO_2Aq = 2M_2S_2O_3Aq + 9S$; $2M_2S_4Aq + 4M_2Cr_2O_7Aq + H_2O$ $= 5M_2S_2O_3Aq + 4Cr_2O_3 + 2MOHAq$ (Döpping, *A.* 46, 172). Spring (*B.* 7, 1157) by heating $(NH_4)_2SO_4$ with P_2S_5 got a large quantity of $(NH_4)_2S_2O_3$, along with $(NH_4)_2S_x$, and also some $(NH_4)_2S_3O_6$, and P compounds; and by the interaction of H_2S and $SO_2.NH_2.ONH_4$ he obtained $(NH_4)_2S_2O_3$. A little $H_2S_2O_3Aq$ is said to be formed by the interaction of steam and molten S (Myers, *A.* 129, 351).

The alkali salts, also the Ca and Sr salts, are readily soluble in water; many of the others are insoluble or only slightly soluble; the insoluble salts are often obtained from solutions of the alkali salts by double decomposition. Thiosulphates are decomposed by heating strongly; alkali salts leave a mixture of sulphate and sulphide; other salts also give off H_2S and S. Aqueous solutions of thiosulphates evolve H_2S when boiled, forming sulphates, or sulphides if the metal of the thiosulphate is ppd. by H_2S.

Aqueous solutions of thiosulphates are decomposed by dilute mineral acids, with separation of S and evolution of SO_2. Salts of the acid used are formed, and $H_2S_2O_3Aq$, which then decomposes to H_2SO_3Aq and S. This reaction has been studied by several chemists (*v.* Berthelot, *C. R.* 108, 971; Vaubel, *B.* 22, 1686, 2703; Vortmann, *B.* 22, 2307; Foussereau, *C.R.* 104, 1842). Colefax (*C. J.* 61, 176) in 1892 examined the interaction of $Na_2S_2O_3Aq$ and acids; he found that when the products of the change are not removed the interaction stops before all the $H_2S_2O_3Aq$ is decomposed. C. determined the effects on the velocity and the limit of the reaction of concentration, increasing the relative mass of the acid used, the nature of the acid, temperature, and the presence of SO_2 in the solution before acidification (reference to older memoirs are given by C.).

Thiosulphates are converted into tetrathionates by the action of I; oxidisers such as HNO_3, $KClO_3$ and HClAq, and $KMnO_4Aq$ produce sulphates. According to Hönig a. Zatzek (*M.* 4, 738), $KMnO_4$ in solution in acetic acid produces dithionates.

For the general qualitative reactions of thiosulphates compared with those of thionates *v.* Debus (*C. J.* 53, 298).

SELENOTHIOSULPHATES M_2SeSO_3 are described as *Thioselenates*, under SELENATES (p. 434).

Constitution of thiosulphates. The formula $SO_2.OM.SM$ is generally adopted for the normal thiosulphates of monovalent metals (Odling, *C. N.* 29, 153; *cf.* Schorlemmer, *C. J.* [2] 7, 254; Williamson, *C. J.* [2] 7, 259). Some chemists, considering the resemblances between thiosulphates and sulphites, have suggested the formula $SO\begin{smallmatrix}\diagup OM\\ \diagdown O.SM\end{smallmatrix}$ (*v.* Blomstrand, *Die Chemie der Jetztzeit* [Heidelberg, 1869], 258; Buchanan, *B.* 3, 485; Michaelis, *G. O.* [5th ed.] 1, 745). The formation of thiosulphates by boiling sulphites with S is readily represented by either formula, according as sulphites are regarded as $SO_2.OM.M$ or $SO.OM.OM$. As the balance of evidence is in favour of the formula $SO_2.OM.M$, it is likely that the salts formed by adding S to the sulphites are $SO_2.OM.SM$. The production of $(NH_4)_2S_2O_3$ by the interaction of $(NH_4)_2SO_4$ and P_2S_5 (Spring, *B.* 7, 1158) also confirms the formula $SO_2.OM.SM$, inasmuch as a thiosulphate is produced in this reaction from a sulphate ($SO_2.ONH_4.ONH_4$ giving $SO_2.ONH_4.SNH_4$). Spring's synthesis of $H_2S_2O_3$ from SO_3 and H_2S—for the actual reaction carried out, viz. formation of $(NH_4)_2S_2O_3$ by first combining SO_3 and NH_3, and then interacting with H_2S, is equivalent to the synthesis of $H_2S_2O_3$ (*v.* S., *l.c.*)—is also in keeping with the formula $SO_2.OM.SM$. By warming EtBr with $Na_2S_2O_3Aq$, Bunte (*B.* 7, 646) obtained the salt $EtNaS_2O_3$. This salt is decomposed by dilute acids giving EtSH and $SO_2.OH.ONa$; when heated it gives off Et_2S_2 and SO_2, leaving Na_2SO_4. These reactions indicate that $EtNaS_2O_3$ is $SO_3Na.EtS$; hence the formula of $Na_2S_2O_3$ is probably $SO_3Na.NaS$. One of the Na atoms in $Na_2S_2O_3$ is then probably in direct union with an atom of S; and as $EtNaS_2O_3$ easily gives $SO_2.OH.ONa$, along with EtSH, it is likely that the formula of this salt is $SO_2.ONa.SEt$, and hence that the formula for $Na_2S_2O_3$ is $SO_2.ONa.SNa$. The formula $SO_2.OH.SH$ makes possible the existence of two isomeric salts $MM'S_2O_3$, viz. $SO_2.OM.SM'$ and $SO_2.OM'.SM$; two such salts are known where M = Na and M' = K. (*v.* POTASSIUM THIOSULPHATE, p. 706).

Ammonium thiosulphate $(NH_4)_2S_2O_3$. Obtained by the interaction of $(NH_4)_2CO_3$ and CaS_2O_3Aq, filtering and evaporating (Rammelsberg, *P.* 56, 298); white, rhombic, deliquescent leaflets, crystallising with xH_2O. Fock a. Klüss (*B.* 22, 3099; 23, 534) obtained the anhydrous salt by reacting on SO_2Aq with $(NH_4)_2S_x$, evaporating at a low temperature and finally over H_2SO_4, and thoroughly drying between filter paper (*cf.* Arppe, *A.* 96, 118). The anhydrous salt is not deliquescent (F. a. K.). *Double salts* are described by F. a. K. (*l.c.*; also *B.* 23, 1753): (1) with CdS_2O_3; (2) with MgS_2O_3; (3) with $K_2S_2O_3$, the salt obtained was $SO_2.OK.SNH_4$. F. a. K. could not obtain $SO_2.ONH_4.SK$; (4) with $Cu_2S_2O_3$ and Cu_2I_2, also with Cu_2I_2 and NH_4I (Brun, *C. R.* 114, 667); (5) with PbS_2O_3 (Rammelsberg, *P.* 56, 308); (6) with HgS_2O_3 (R., *l.c.*).

Barium thiosulphate $BaS_2O_3.aq$. A white pp. obtained by mixing $Ba(C_2H_3O_2)_2Aq$ and $Na_2S_2O_3Aq$, and completing ppn. by alcohol; loses all water at 170°, at red heat gives $BaS, BaSO_3, BaSO_4$, and S (H. Rose, *P.* 21, 437; Rammelsberg, *P.* 56, 295).

Double salts. (1) With CdS_2O_3 (Fock a. Klüss, *B.* 23, 1753); (2) with $Cu_2S_2O_3$ (Cohen, *C. J.* 51, 38); (3) with PbS_2O_3 (Rammelsberg, *P.* 56, 308).

Cadmium thiosulphate $CdS_2O_3.2aq$ (F. a. K., *B.* 23, 534); *double salts* with (1) $Na_2S_2O_3$, (2) $K_2S_2O_3$, (3) SrS_2O_3 (F. a. K., *B.* 23, 1753; Vortmann a. Padberg, *B.* 22, 2637).

Calcium thiosulphate $CaS_2O_3.6aq$. Formed by mixing hot conc. solutions of $CaCl_2$ and $Na_2S_2O_3$, evaporating under 60°, separating NaCl, which crystallises first, and allowing to cool (Kessler, *P.* 74, 282). Also obtained by heating $CaSO_3$ and S with water, or by boiling milk of lime with S, passing in SO_2, and crystallising below 60° (Herschel, *N. Ed. P. J.* 1, 8, 296; 2, 154). Forms large, clear, six-sided, triclinic prisms, that effloresce in air at 40°; S. 100 at 3° (H., *l.c.*). Conc. solution gives $CaSO_3$ and S by heating above 60°. Rammelsberg (*P.* 56, 308) describes a *double salt* with PbS_2O_3.

Cobalt thiosulphate $CoS_2O_3.6aq$ (Rammelsberg, *P.* 56, 398; Fock a. Klüss, *B.* 22, 3310). A *double salt* with $Na_2S_2O_3$ is described by Vortmann a. Padberg (*B.* 22, 2637).

Copper thiosulphates. According to von Hauer (*W. A. B.* 13, 443) an *acid cuprous salt* $Cu_2H_4(S_2O_3)_3$, is obtained, in microscopic, golden-yellow needles, by adding conc. $CuSO_4Aq$ to $Na_2S_2O_3Aq$ till the liquid is deep yellow, and gently warming, washing the pp. with water and alcohol, and drying over H_2SO_4. *Double salts* of $Cu_2S_2O_3$: (1) with BaS_2O_3 (Cohen, *C. J.* 51, 38); (2) with $K_2S_2O_3$ (C., *l.c.*; Rammelsberg, *P.* 56, 321); (3) with $Ag_2S_2O_3$ (C., *l.c.*); (4) with $Na_2S_2O_3$ (Lenz, *A.* 40, 99; Siewert, *J.* 1866, 257; Kessel, *B.* 10, 1677, 2000; Schütte, *J. pr.* 70, 249; Vortmann, *M.* 9, 165).

Iron thiosulphate. The *ferrous salt* $FeS_2O_3.5aq$ was obtained by Vortmann a. Padberg (*B.* 22, 2637) by rubbing BaS_2O_3 with conc. $FeSO_4Aq$ (the salts being present in the ratio of equal numbers of molecules), filtering from $BaSO_4$, adding a mixture of alcohol and ether, and allowing the green, oily liquid that separated to stand for some days. Small green crystals; very sol. water; solution is decomposed by boiling, with separation of FeS. A *double salt* with $Na_2S_2O_3$ is described by V. a. P. (*l.c.*). For accounts of former attempts to prepare pure ferrous thiosulphate *v.* Fordos a. Gélis (*J. Ph.* [3] 4, 333); Berthelot (*A. Ch.* [5] 2, 58); Vogel (*J. pr.* 8, 102); Koene (*P.* 63, 245, 431); Rammelsberg (*P.* 56, 306).

No *ferric thiosulphate* has been isolated.

Lead thiosulphate PbS_2O_3. Obtained by adding $Na_2S_2O_3Aq$ to $Pb(NO_3)_2Aq$, or $Pb(C_2H_3O_2)_2Aq$, and washing the pp. with cold water. A white solid; very sl. sol. water; sol. solutions of alkali thiosulphates (*v.* Pape, *J.* 1864. 57; Letts, *C. J.* [2] 8, 424). For reaction with PCl_5—giving $PbCl_2$, HCl, SO_2, $SOCl_2$, $POCl_3$ and probably $PSCl_3$—*v.* Buchanan (*B.* 8, 485). Rammelsberg (*P.* 56, 308) has described *double salts* with the thiosulphates of NH_4, Ba, Ca, K (*v.* also Spring, *B.* 7, 1157), and Na (*v.* also Vortmann a. Padberg, *B.* 22, 2637).

Lithium thiosulphate $Li_2S_2O_3.3aq$ (*v.* Fock a. Klüss, *B.* 22, 3096).

Magnesium thiosulphate $MgS_2O_3.6aq$. By passing SO_2 into MgSAq till colourless, boiling $MgSO_3$ in SO_2Aq with S, or adding BaS_2O_6Aq to $MgSO_4Aq$ and filtering, a solution is obtained which on evaporation at a low temperature gives small, white, prismatic crystals of this salt. Loses $3H_2O$ at 170°, and gives off SO_2 and S at red heat, leaving $MgSO_4$ and MgO (Herschel, *N. Ed. P. J.* 1, 8, 296; 2, 154; Rammelsberg, *P.* 56, 303; Fock a. Klüss, *B.* 22, 3310). *Double salts* (1) with $(NH_4)_2S_2O_3$, (2) with $K_2S_2O_3$ are described by R. (*l.c.*; *v.* also Kessler, *P.* 74, 256; also F. a. K., *B.* 23, 534).

Manganese thiosulphate $MnS_2O_3.5aq$. Formed similarly to $FeS_2O_3.5aq$ (Vortmann a. Padberg, *B.* 22, 2637). A *double salt* with $Na_2S_2O_3$ is described by V. a. P. (*l.c.*).

Mercury thiosulphates. Neither the mercurous nor the mercuric salt has been isolated. Addition of a thiosulphate to solution of a mercurous salt ppts. Hg_2S; with a mercuric salt, a compound of HgS with the mercuric salt employed is said to be formed (Rammelsberg, *P.* 56, 314). *Double salts* of *mercurous thiosulphate* with (1) $(NH_4)_2S_2O_3$, (2) $Cu_2S_2O_3$, (3) $Na_2S_2O_3$ are described by Rammelsberg (*l.c.*); and a double salt of *mercuric thiosulphate* with $K_2S_2O_3$ by Vortmann a. Padberg (*B.* 24, 1351).

Nickel thiosulphate $NiS_2O_3.6aq$ (Rammelsberg, *P.* 56, 309; Fock a. Klüss, *B.* 22, 3310). For a *double salt* with $Na_2S_2O_3$ *v.* Vortmann a. Padberg (*B.* 22, 2637).

Platinum thiosulphate. Not isolated; but Schottländer (*A.* 140, 200) describes a *double salt* $PtS_2O_3.3Na_2S_2O_3.10aq$.

Potassium thiosulphate $K_2S_2O_3$. Obtained by boiling conc. K_2SO_3 with excess of S; or by adding hot $K_2Cr_2O_7Aq$ to hot K_2S_5Aq, little by little, waiting after each addition till the separated Cr_2O_3 is pure green in colour

$$(2K_2S_5Aq + 4K_2Cr_2O_7Aq + H_2O = 5K_2S_2O_3Aq + 2KOHAq + 4Cr_2O_3);$$

(Döpping, *A.* 46, 172; Kessler, *P.* 74, 274). In either case the filtered solution is evaporated to the crystallising point, and the crystals of $K_2S_2O_3.xH_2O$ are heated to c. 180°. By evaporating at 30°, thin, four-sided, deliquescent prisms are obtained of the *hydrated salt* $3K_2S_2O_3.H_2O$ (Rammelsberg, *P.* 56, 296; Kessler, *l.c.*; Fock a. Klüss, *B.* 22, 3096). This hydrate is very sol. water, but insol. alcohol; it loses all water at c. 180°; heated more strongly it decomposes to K_2S_5 and K_2SO_4 (R., *l.c.*). Other hydrates are described by D. a. P., *l.c.* (*v.* also Plessy, *A. Ch.*

[3] 11, 182; F. a. K., *l.c.*). The final products of the action of SO_2 on $K_2S_2O_3Aq$ are $K_2S_3O_6Aq$, $K_2S_4O_6Aq$, and $K_2S_5O_6Aq$ (Debus, *C. J.* 53, 343).

Double salts.—(1) with $(NH_4)_2S_2O_3$ (Fock a. Klüss, *B.* 23, 534); the salt obtained was $SO_2.OK.SNH_4$, the isomeric salt $SO_2.ONH_4.SK$ could not be isolated; (2) with $Bi_2(S_2O_3)_3$ (Carnot, *C. R.* 83, 338); (3) with CdS_2O_3 (F. a. K., *B.* 23, 534); (4) with $Cu_2S_2O_3$ (Cohen, *C. J.* 51, 38); (5) with $HgCy_2$ (F. a. K., *B.* 24, 1351); (6) with HgS_2O_3 (F. a. K., *l.c.*); (7) with PbS_2O_3 (Rammelsberg, *P.* 56, 308; Spring, *B.* 7, 1157); (8) with $Ag_2S_2O_3$ (Cohen, *C. J.* 51, 38; Schwicker, *B.* 22, 1728, describes $KAgS_2O_3.NH_3$). (9) With $Na_2S_2O_3$ two salts are obtained: (i.) $SO_2.OK.NaS.2aq$, by the interaction of Am_2S_5Aq and $NaKSO_3.2aq$; (ii.) $SO_2.SK.ONa.2aq$, by the interaction of Am_2S_5Aq and $KNaSO_3$ (*v.* SULPHITES, p. 587); the first salt melts at c. 57° and has S. = 213·7 at 15°, heated with EtBr it gives $SO_2.OK.SEt$; the second salt melts at c. 62° and has S. = 105·3 at 15°, heated with EtBr it gives $SO_2.ONa.SEt$ (Schwicker, *B.* 22, 1728).

Silver thiosulphate $Ag_2S_2O_3$. This salt has probably not been isolated pure. On adding dilute $AgNO_3Aq$ to $K_2S_2O_3Aq$ a white pp. is formed, and is dissolved on shaking; addition of more $AgNO_3Aq$ produces a greyish, flocculent pp., which is a mixture of $Ag_2S_2O_3$ and Ag_2S. By treating this pp. with NH_3Aq, filtering from Ag_2S, exactly neutralising the filtrate by HNO_3Aq, and quickly drying the white flocculent pp. that formed between filter paper, Herschel (*N. Ed. P. J.* 1, 26, 398; 2, 154) obtained fairly pure $Ag_2S_2O_3$. A white powder; slightly soluble water; solution has a sweet taste; decomposes readily to Ag_2S and H_2SO_4Aq.

Double salts. Ag_2O and Ag salts generally dissolve readily in solutions of alkali thiosulphates, forming double salts, either of the form $2AgMS_2O_3.aq$, or of the form $Ag_2M_4(S_2O_3)_3.2aq$ (Herschel, *l.c.*). (1) With $(NH_4)_2S_2O_3$; by adding excess of AgCl to $(NH_4)_2S_2O_3Aq$, and washing the white crystalline pp., $2Ag(NH_4)S_2O_3.aq$ is obtained. Using less AgCl and ppg. the solution by alcohol produces $Ag_2(NH_4)_4(S_2O_3)_3.2aq$ (H., *l.c.*). (2) With $Na_2S_2O_3$; addition of $AgNO_3Aq$, drop by drop, with constant shaking, to $Na_2S_2O_3Aq$, till a permanent pp. begins to form, followed by addition of alcohol, ppts. $Ag_2Na_4(S_2O_3)_3.2aq$; the salt is washed with alcohol, and dried *in vacuo* (Lenz, *A.* 40, 94); when the mother-liquor from this salt is allowed to evaporate $2AgNaS_2O_3.aq$ is deposited (Herschel, *l.c.*; *cf.* Lenz, *l.c.*). The second of these salts is much less soluble in water than the first; it dissolves in $Na_2S_2O_3Aq$, with formation of $Ag_2Na_4(S_2O_3)_3.2aq$. Both salts are decomposed by boiling their aqueous solutions, with formation of Ag_2S. (3) With $K_2S_2O_3$; two salts are known similar to the sodium salts. Schwicker (*B.* 22, 1738) describes the compound $AgKS_2O_3.NH_3$. Herschel (*l.c.*) obtained double salts with CaS_2O_3 and with SrS_2O_3.

Sodium thiosulphate $Na_2S_2O_3.5aq$.

Formation.—1. By boiling Na_2SO_3Aq with S.—2. By passing SO_2 into solution of sodium polysulphides.—3. By the action of SO_2 on *soda waste* suspended in water, whereby CaS_2O_3Aq is formed; followed by addition of Na_2SO_4, filtration from $CaSO_4$, and evaporation.

Preparation.—$Na_2SO_3.xaq$ is dissolved in a little water, the solution is boiled with flowers of sulphur for a considerable time, and filtered; the clear, colourless liquid is evaporated to the crystallising point, and the crystals that separate are purified by recrystallisation from water.

Properties.—Large, white, monoclinic prisms; S.G. 1·736 at 10° (Kopp, *J.* 8, 45; *cf.* Schiff, *J.* 12, 41; Smith, *Am. J. Pharm.* 53, 148). Melts at 45° in the water of crystallisation (Kopp, *J.* 8, 45); at 48·5° (Tilden, *C. J.* 45, 268). The crystals are dehydrated by keeping *in vacuo* over H_2SO_4, or by heating to 100°. S. 49·75 at 0°, 69·44 at 20°, 104·16 at 40°, 192·3 at 60° (Kremers, *P.* 99, 50). An aqueous solution of the salt is easily supersaturated; thus Schiff (*A.* 113, 350) dissolved 171 parts $Na_2S_2O_3.5aq$ (= 108·9 parts $Na_2S_2O_3$) in 100 parts water at 19·1°, and Kremers obtained a solution of 217·4 parts $Na_2S_2O_3$ in 100 parts water at the ordinary temperature. According to Baumhauer (*J. pr.* 104, 148), a supersaturated solution may be cooled to −10° without crystallising; addition of a crystal of the salt causes rapid crystallisation, with the evolution of much heat (*cf.* Parmentier a. Amat, *C. R.* 98, 735) Solution of $Na_2S_2O_3.5aq$ in water is accompanied by the disappearance of much heat; Rüdorff (*B.* 2, 68) says that 110 parts $Na_2S_2O_3.5aq$ dissolving in 100 parts water lower the temperature from 10·7° to −8°, *i.e.* through 18·7°. Schiff (*A.* 113, 350) gives the following data for S.G. and composition of aqueous solutions of $Na_2S_2O_3.5aq$:—

S.G. of sol.	P.c. $Na_2S_2O_3.5aq$	P.c. $Na_2S_2O_3$	S.G. of sol.	P.c. $Na_2S_2O_3.5aq$	P.c. $Na_2S_2O_3$

$Na_2S_2O_3.5aq$ is insol. alcohol.

According to Jochum (*C. C.* 1885. 642), a *trihydrated salt* $Na_2S_2O_3.3aq$ is obtained by adding alcohol to a saturated solution of the ordinary salt, removing the oily liquid that separates, and adding to it 98 p.c. alcohol. According to Parmentier a. Amat (*C. R.* 98, 735), $Na_2S_2O_3.5aq$ is obtained crystallised in needles, melting at c. 32°, by placing a supersaturated solution of the ordinary salt in a freezing mixture in a closed vessel.

Reactions.—1. *Heat* decomposes $Na_2S_2O_3$; the change begins at c. 220° with separation of S, at c. 400° Na_2SO_4 and Na_2S_5 are formed, and at a higher temperature more S is given off, and Na_2SO_4 and Na_2S remain.—2. $Na_2S_2O_3Aq$ interacts with *iodine* in KIAq to form NaIAq and $Na_2S_4O_6Aq$; according to Villiers (*C. R.* 108, 402) some $Na_2S_3O_6$ is also formed. With a mixture of Na_2SO_3 and $Na_2S_2O_3$ in solution I produces NaIAq, Na_2SO_4Aq and $Na_2S_4O_6Aq$ (Colefax, *C. J.* 61, 198, 1083).—3. $Na_2S_2O_3$ is oxidised by *potassium permanganate* solution; in alkaline solutions the oxidation is complete to Na_2SO_4Aq according to Hönig a. Zatzek (*M.* 4, 738); Glaser (*M.* 6, 329) says that the oxidation is also complete in neutral solutions; Luckow (*Fr.* 32, 53) represents the oxidation, on boiling, either in neutral, acid, or alkaline solution as producing Na_2SO_4 and $Na_2S_2O_6$.—4. *Acids* interact with $Na_2S_2O_3Aq$, forming Na salts of the acids, and $H_2S_2O_3Aq$, which then decomposes to H_2SO_3Aq and S; when the products are not removed from the solution the reaction stops before all the $H_2S_2O_3$ is decomposed (Colefax, *C. J.* 61, 176; and *v.* beginning of article THIOSULPHATES, p. 705).

Combinations.—1. With *water* (*v. supra, Properties*).—2. With various *thiosulphates* to form *double salts.* Double salts with CdS_2O_3, CoS_2O_3, FeS_2O_3, PbS_2O_3, MnS_2O_3, NiS_2O_3, $Tl_2S_2O_3$, and ZnS_2O_3 are described by Vortmann a. Padberg (*B.* 22, 2637); Fock a. Klüss (*B.* 23, 1753) also describe that with CdS_2O_3. Rammelsberg (*P.* 56, 308) prepared salts with PbS_2O_3 and $Hg_2S_2O_3$. For a double salt with HgS_2O_3 *v.* Schwicker (*B.* 22, 1728). For the double salts with $K_2S_2O_3$ *v.* POTASSIUM THIOSULPHATE, *double salts*, No. (9) (p. 707), and for those with $Ag_2S_2O_3$ *v.* SILVER THIOSULPHATE, *double salts*, No. (2) (p. 707). Schottländer (*A.* 140, 200) describes a double salt $3Na_2S_2O_3.PtS_2O_3.10aq$.

Strontium thiosulphate $SrS_2O_3.5aq$. Prepared like the Ba salt (Herschel, *N. Ed. P. J.* 1, 26, 398; 2, 154; Kessler, *P.* 74, 274). Fock a. Klüss (*B.* 22, 3310) describe a salt $SrS_2O_3.aq$.

Thallium thiosulphate $Tl_2S_2O_3$. A white, crystalline pp., formed by adding $Na_2S_2O_3Aq$ to fairly conc. TlOHAq (Crookes, *C. J.* 17, 136; Hebberling, *A.* 184, 11). For a *double salt* with $Na_2S_2O_3$ *v.* Werther (*J. pr.* 92, 130); Vortmann a. Padberg (*B.* 22, 2637); also Jochum (*C. C.* 1885. 642).

Zinc thiosulphate ZnS_2O_3. Prepared by double decomposition from $ZnSO_4Aq$ and BaS_2O_3Aq (*v.* Rammelsberg, *P.* 56, 295; Fordos a. Gélis, *J. pr.* 29, 291). For a compound with NH_3 *v.* R. (*l.c.*). For a *double salt* with $Na_2S_2O_3$ *v.* Vortmann a. Padberg (*B.* 22, 2637).

M. M. P. M.

THIOSULPHURIC ACID $H_2S_2O_3Aq$. This acid almost certainly exists in the liquid obtained by adding a dilute weak acid to dilute $Na_2S_2O_3Aq$, the acid and salt being mixed in equivalent quantities; the $H_2S_2O_3Aq$ soon begins to decompose to H_2SO_3Aq and S. Landolt (*B.* 16, 2958) has made an extensive investigation into the conditions and time of existence of $H_2S_2O_3$ in solution. Thomsen (*Th.* 2, 256) gives the thermal data; $[SO^2Aq,S] = -9310$; $[SO^2,S,Aq] = -1610$.

For the salts of $H_2S_2O_3$ *v.* THIOSULPHATES.

M. M. P. M.

THIOTOLENE *v. Methyl-thiophene.*

THIO-*o*-TOLUIC ACID. *Amide* $C_6H_4Me.CS.NH_2$. [88°]. Formed from *o*-toluic nitrile (Gabriel a. Heymann, *B.* 24, 786).

Thio-*p*-toluic acid. *Amide.* [168°]. Formed by passing H_2S into an alcoholic solution of *p*-toluic nitrile (Paterno a. Spica, *B.* 8, 441). Yellowish needles. Zinc and HClAq yield $C_6H_4Me.CH_2NH_2$.

THIO-TOLUIDINE *v.* DI-AMIDO-DI-TOLYL SULPHIDE.

THIO-*p*-TOLYL-DI-PHENYL-DI-GUANIDINES *v.* DI-PHENYL-DI-GUANIDO-DI-TOLYL SULPHIDE and DI-PHENYL-DI-CARBIMIDO-TETRA-AMIDO-TETRA-TOLYL DISULPHIDE.

THIO-TOLYL-DI-PHENYL-THIO-UREA *v.* DI-PHENYL-DI-THIOURAMIDO-DI-TOLYL SULPHIDE.

THIO-URAMIDO-BARBITURIC ACID $C_5H_6N_4SO_3$ *i.e.* $NH_2.C(NH).S.CH\left<\begin{matrix}CO.NH\\CO.NH\end{matrix}\right>CO$. Formed by the action of thio-urea on an aqueous solution of chloro-, bromo-, or di-bromo-barbituric acid (Mulder, *B.* 12, 2309; Trzcinski, *B.* 16, 1057). Formed also by heating alloxan with thio-urea and alcoholic SO_2 at 100° (Nencki, *B.* 4, 722; 5, 451). Slender needles, insol. water, sol. hot HClAq. Converted by boiling KOHAq into thio-dialuric acid $C_4H_4N_2SO_3$ $1\frac{1}{2}aq$ (?) which yields KA′aq. H_2SO_4 ($\frac{1}{2}$ pt.) at 150°–160° forms uro-sulphinic acid $C_5H_4N_4SO_2$.

THIO-URAMIDO-BENZENE *p*-SULPHONIC ACID. The salt $NH_2.CS.NH.C_6H_4.SO_3K$, formed by heating potassium sulphocyanide with amido-benzene *p*-sulphonic acid at 140°, crystallises from dilute alcohol in aggregates of thin needles (Pellizzari, *A.* 248, 156).

***m*-THIO-URAMIDO-BENZOIC ACID** $NH_2.CS.NH.C_6H_4.CO_2H$. [187°]. Formed from *m*-amido-benzoic acid and potassium sulphocyanide (Arzruni, *B.* 4, 406). Formed also by allowing a solution of *m*-cyanamido-benzoic acid in colourless ammonium sulphide to stand for 24 hours (Traube, *B.* 15, 2118). Needles. Converted by ammoniacal $AgNO_3$ into *m*-uramido-benzoic acid. Not coloured by $FeCl_3$.

***p*-THIO-URAMIDO-BENZYL-THIO-UREA** $NH_2.CS.NH.C_6H_4.CH_2.NH.CS.NH_2$. *p-ω-di-thi-uramido-toluene.* [176°]. Formed by heating *p*-amido-benzyl-amine hydrochloride (1 mol.) with potassium sulphocyanide (2 mols.) in aqueous solution (Amsel a. Hofmann, *B.* 19, 1289). White needles.

THIO-URAMIDO-BUTYRIC ACID. *Anhydride* $NH:C\left<\begin{matrix}S-CHEt\\NH.CO\end{matrix}\right.$. [200°]. Formed from *α*-bromo-*n*-butyric acid and thio-urea (Andreasch, *M.* 8, 419). Needles, v. sol. hot water.

Thio-uramido-iso-butyric acid. *Anhydride* $C_5H_8N_2SO$ *i.e.* $NH:C\left<\begin{matrix}S-CMe_2\\NH.CO\end{matrix}\right.$. [242°]. Formed from bromo-isobutyric acid and thio-urea (Andreasch, *M.* 8, 410). Plates, sl. sol. water. Oxidised by HCl and $KClO_3$ to urea and *α*-sulpho-iso-butyric acid.

***o*-THIO-URAMIDO-CINNAMIC ACID** $NH_2.CS.NH.C_6H_4.CH:CH.CO_2H$. [236°–239°]. Got by heating the sulphocyanide of *o*-amido-cinnamic acid $C_6H_4(NH_2.HSCy)CH:CH.CO_2H$

[152°] at 115° (Rothschild, *B.* 23, 3342). V. sol. hot HOAc and NH_3Aq.

α-Thio-ψ-uramido-cinnamic acid $C_{10}H_{10}N_2SO_2$ *i.e.* $NH:C(NH_2).S.C(CO_2H):CHPh$. Formed from benzoic aldehyde, thiohydantoïn, and NaOHAq (Andreasch, *M.* 8. 421). Needles (from alcohol), decomposed by alkalis.

β-THIO-ψ-URAMIDO-PROPIONIC ACID $NH:C(NH_2).S.CH_2.CH_2.CO_2H$. Formed by heating *β*-iodo-propionic acid with thio-urea and water and a little NaOH (Andreasch, *M.* 6, 831). Small pyramids (containing 2aq), sl. sol. cold water and cold alcohol. Decomposed by baryta into cyanamide and $CH_2(SH).CH_2.CO_2H$. $KClO_3$ and HCl yield *β*-sulpho-propionic acid.

ωp-**DI-THIO-URAMIDO-TOLUENE** *v.* THIO-URAMIDO-BENZYL-THIO-UREA.

DI-*p*-THIO-URAMIDO-DI-TOLYL-*o*-SULPHIDE [2:1:4] $S(C_6H_3Me.NH.CS.NH_2)_2$. *Thio-p-tolyl-di-thiurea.* [121°]. Formed by evaporating to dryness an aqueous solution of di-*p*-amido-di-tolyl sulphide, hydrochloride and ammonium sulphocyanide (Truhlar, *B.* 20, 669). White amorphous powder. Sol. alcohol and benzene, sl. sol. ether.

THIO-UREA CSN_2H_4 *i.e.* $CS(NH_2)_2$ or $HS.C(NH_2):NH$. Mol. w. 76. [170°]. S. 9 in the cold (Volhard, *J. pr.* [2] 9, 13).

Formation.—1. By heating dry ammonium sulphocyanide for two hours at 170°, cooling to 100°, adding an equal weight of water at 80°, filtering, and allowing to crystallise (Emerson Reynolds, *C. J.* 22, 1; Claus, *A.* 179, 113; Smolka a. Friedreich, *M.* 10, 90).—2. By the action of tin and HCl, or of HI, on persulphocyanic acid $C_2H_2N_2S_3$ (Glutz, *A.* 154, 39).—3. By passing dry H_2S into an ethereal solution of cyanamide (Baumann, *B.* 6, 1375).—4. By allowing a solution of cyanamide, mixed with yellow ammonium sulphide, to stand for a day (Baumann, *B.* 8, 26).—5. From cyanamide and thioacetic acid.—6. Together with urea by the action of ammonia on COS (Berthelot, *C. R.* 94, 1069).

Properties.—Silky trimetric needles, melting at 170°. After one fusion it melts at 149° (Prätorius, *J. pr.* [2] 21, 141). V. sol. water, nearly insol. alcohol and ether. Tastes bitter, not coloured by $FeCl_3$. According to Armstrong (*C. J. Proc.* 8, 2), the molecule of thio-urea is $C_2S_2N_4H_8$.

Reactions.—1. *Water* at 140° forms ammonium sulphocyanide. *Alcohol* at 100° acts in like manner (Haller, *Bl.* [2] 45, 706).—2. An alcoholic solution of *nitrous ether* quickly converts it into ammonium sulphocyanide.—3. Prolonged *heating* at 170° also converts it into ammonium sulphocyanide. At 180° it slowly forms guanidine sulphocyanide and ammonium tri-thio-carbonate. Nitrous acid gives off nitrogen.—4. KOH at 100° slowly forms NH_3, KSH, K_2CO_3, and a little KCyS. Alcoholic potash acts in like manner (Haller, *C. R.* 102, 974). H_2SO_4 and HCl act in the same way.—5. Aqueous $KMnO_4$ forms urea and other products (Maly, *M.* 11, 277).—6. *Oxidising agents* (*e.g.* H_2O_2, $K_2Cr_2O_7$, KNO_2, $KMnO_4$, and iodine) form $S_2(C(NH_2):NH)_2$, which has an insoluble nitrate (Storch, *M.* 11, 452).—7. Ammoniacal $AgNO_3$ forms urea and Ag_2S.—8. HgO, added to a cold aqueous solution, produces cyanamide. PbO acts in like manner. At 100° the product is dicyandiamide (Hofmann, *B.* 2, 605).—9. *Acetoacetic ether* reacts forming an ether $C_5H_7N_2SO(OEt)$, which on saponification yields $CS\left\langle\begin{matrix}NH.CMe\\NH.CO\end{matrix}\right\rangle CH$, v. sl. sol. water (Behrend, *B.* 19, 219).—10. $CCl_3.COCl$ forms $C_4H_5Cl_3N_2S_2O_2$, crystallising in slender needles, m. sol. alcohol, sl. sol. water, v. sl. sol. ether; converted by Br into $CCl_3.SO_2Br$ (McGowan, *C. J.* 49, 191; 51, 669; *J. pr.* [2] 36, 220). $CCl_3.SO_2Cl$ added to an alcoholic solution of thio-urea forms the chloride $Cl_2CSN_2H_4$, which is ppd. on adding ether, while the filtrate contains the compound $(CSN_2H_4)_2(CCl_3.SO_2)_2$ [125°], which is more sol. alcohol than water, and gives with Br a pp. of $CCl_3.SO_2Br$.—11. $CCl_3.SO_2NH_4$ in alcohol forms flat prisms of $(CSN_2H_4)CCl_3SO_2H$ [139°], m. sol. water and ether, v. sol. alcohol, converted by Br into $CCl_3.SO_2Br$ (M'Gowan, *C. J.* 51, 667; *J. pr.* [2] 36, 219).—12. *Chloro-acetone* forms $(NH_2.CS.NH.CH_2.CO.CH_3)HCl$ [126°] (Pawlewski, *B.* 21, 402).—13. $ClCO_2Et$ forms $(NH_2.CS.NH.CO_2Et)HCl$ [117°].—14. $CH_2Cl.OH$ gives $C_2H_4N_2S$, a white amorphous powder, insol. water, nearly insol. all usual menstrua, reconverted into thio-urea by HClAq (von Hemmelmayr, *M.* 12, 89).—15. *Di-bromo-succinic acid* forms fumaric acid on heating (Nencki a. Sieber, *J. pr.* [2] 25, 74).—16. A hot conc. solution of *di-bromo-pyruvic acid* forms 'sulphuvinuric acid' $C_4H_4N_2SO_2$, which crystallises with 2aq, reduces Fehling solution to Cu_2O in the cold, and to a copper mirror on warming, and yields the salts CaA'_2, MgA'_2, ZnA', HA'HCl, HA'HBr, and $HA'HNO_3$aq (N. a. S.).—17. *Bromo-pyruvic ether* forms amido-thiazole carboxylic ether  $S\left\langle\begin{matrix}CH=CCO_2Et\\C(NH_2):N\end{matrix}\right.$ [173°] (Steude, *A.* 261, 30).—18. *Bromo-acetoacetic ether* gives *μ*-amido-thiazyl-acetic ether  $S\left\langle\begin{matrix}CH=C.CH_2.CO_2Et\\C(NH_2):N.\end{matrix}\right.$ [94°], which yields an acid [c. 130°], split up on fusion into CO_2 and amido-methyl-thiazole (Steude). *α-Chloro-acetoacetic ether* forms $C_3NSMe(NH_2).CO_2Et$ [175°] (Zürcher, *A.* 250, 281).—19. Thio-urea heated with an alcoholic solution of *chloro-acetic acid* and *phenyl-hydrazine* forms $C_9H_9N_3SO$ [175°] (Probst, *J. pr.* [2] 45, 416).—20. Fusion with (*β*)-*iodopropionic acid* and a little water forms $C_4H_8N_2SO_2$ [176°], which crystallises from water in needles (containing 2aq), sl. sol. alcohol, insol. ether (Andreasch, *M.* 6, 832).—21. *Di-chloro-acetic acid* forms thiohydantoïn. *α-Bromo-propionic acid* forms methyl-thiohydantoïn (206° uncor.) (Dixon, *C. J.* 63, 815).—22. *Aldehyde* heated in a sealed tube with thio-urea forms $CSN_2H_4(CHMe)$, which is sl. sol. ether and cold alcohol, and is decomposed by hot water (Reynolds, *C. N.* 24, 87).—23. *Succinic anhydride* at 140° forms $C_8H_8N_2SO_3$ [211°].—24. *Citraconic anhydride* at 130° forms $C_6H_8N_2SO_2$ [223°] (Pike, *B.* 6, 1104).—25. *Acetyl-acetone* and a small quantity of HClAq form $CH_2(CMe:N.CS.NH_2)_2HCl$ [219°]. In presence of excess of HCl the product is  $CH_2\left\langle\begin{matrix}CMe:N\\CMe:N\end{matrix}\right\rangle CS$ [210°] (Evans, *J. pr.* [2] 48, 503).

Salts.—$B'HNO_3$. Crystalline.—B'HCl. Formed from the stannous double chloride and

H_2S. Crystalline.—$B'HI$. Tables.—B'_4NH_4Cl. [154°]. Felted crystalline mass (Reynolds, *C. J.* 59, 385).—B'_4NH_4I. [186°].—$B'_2H_2PtCl_6$. Yellow prisms, v. sol. water and alcohol. Can be dried at 100°.—B'_2HPtCl_3. Got when saturated solutions of thio-urea and $PtCl_4$ are mixed. Dark-red prisms, insol. water, alcohol and ether.—B'_2AuCl. Yellow monoclinic crystals, got by adding $AuCl_3$ to a saturated solution of thio-urea.—$B''TlSO_4$.—B'_2CuSO_4. White silky needles. Got by mixing conc. solutions of thio-urea and $CuSO_4$.—$B'_5Cu_2(SO_4)$ 2aq.—B'_3CuCl. Colourless dimetric crystals, sol. water, but ppd. by HCl and KCl. Alkaline in reaction. Attacked by H_2S with difficulty. Does not absorb CO (Rathke, *B.* 17, 301).—$B'_2Cu_2Cl_2$ aq. Ppd. by adding $CuCl_2Aq$ to aqueous thio-urea (Rathke, *B.* 14, 1779; 17, 301). Minute needles, insol. water.—B'_2CuCl. Flat needles. Formed by mixing the two preceding salts into which it is decomposed by water.—$B'4HgO$.—$B'_2(HgO)_3$ 3aq. Ppd. by adding neutral $Hg(NO_3)_2$ to a dilute solution of thio-urea (Emerson Reynolds, *A.* 150, 235; Kurnakoff, *B.* 24, 3956). Crystalline. Loses thio-urea on washing with water.—B'_4HgCl_2: large crystals, v. sol. water.—B'_2HgCl_2: minute needles, nearly insol. water (Claus, *B.* 9, 227).—$B'HgI_2$ (Maly, *B.* 9, 173).—$B'HgCyS$. Needles, decomposed by heat into dicyandiamide, HCy, and HgS (Nencki, *B.* 6, 598).—B'_2PbCl_2: needles (Claus, *A.* 179, 135).—$B'Pb(CyS)_2$.—B'_2SnCl_2.—B'_2ZnCl_2: spherical groups of prisms (from water).—B'_2CdSO_4.—B'_8SiBr_4 (Emerson Reynolds, *C. J.* 51, 202).—B'_2Ag_2O 4aq. Crystalline.—$B'AgNO_3$ (K.).—B'_2AgNO_3. [141°]. Silky crystals, sol. hot alcohol (Emerson Reynolds, *C. J.* 61, 249).—B'_2AgCl. [171°]. Needles, m. sol. hot alcohol.—B'_2AgBr. [121°].—B'_2AgI.—B'_2AgCy. [126°].—$B'_8Ag_2C_2O_4$: needles.

Chloride $(CSN_2H_4)_2Cl_2$. Formed by passing Cl into a conc. alcoholic solution of thio-urea (Claus, *A.* 179, 139). Formed also by the action of $CCl_3.SO_2Cl$, and of ICl, ICl_3, or $POCl_3$ on thio-urea (M'Gowan, *C. J.* 49, 191; *J. pr.* [2] 33, 188). Small needles, v. sol. water, m. sol. alcohol, insol. ether. Decomposed by alkalis, yielding cyanamide. Alcoholic KI removes chlorine, setting thio-urea free. Dilute HNO_3 forms crystals of $(CSN_2H_4)_2(NO_3)_2$, which is sl. sol. water, insol. alcohol and ether.

Bromide $(CSN_2H_4)_2Br_2$. Formed by adding Br to an alcoholic or cold aqueous solution of thio-urea; in aqueous solution excess of Br produces urea (Claus, *A.* 179, 138; M'Gowan, *C. J.* 51, 378; *J. pr.* [2] 36, 216). Crystals. Its aqueous solution deposits S when heated. Sodium-amalgam reproduces thio-urea.

Iodide $(CSN_2H_4)_2I_2$. Formed from thio-urea, I, and alcohol (M'Gowan, *J. pr.* [2] 33, 192). Prisms.

Methylo-iodide $(CSN_2H_4)MeI$. [117°]. Formed slowly by combination of thio-urea with MeI in the cold (Bernthsen a. Klinger, *B.* 11, 493). Prisms, v. sol. water and alcohol. AgCl gives the chloride, which forms the platinochloride $(B'MeCl)_2PtCl_4$ aq.

Ethylo-chloride $B'EtCl$. Crystals.

Ethylo-bromide $(CSN_2H_4)EtBr$. Hexagonal plates (Claus a. Siegfried, *A.* 179, 145). Decomposes at 100°.

Ethylo-iodides $(CSN_2H_4)EtI$. Crystalline. Gives with moist Ag_2O a base. Boiling aqueous alkalis liberate mercaptan.—$B'_2Et_2PtCl_6$ (dried at 100°). Tables.—B'_2EtI. Needles (from alcohol) (Claus, *B.* 8, 41).

Benzylo-chloride $(CSN_2H_4)C_7H_7Cl$. [168°]. Formed from benzyl chloride and thio-urea. Yields unstable benzyl-thio-urea $CSN_2H_3C_7H_7$ [72°], which decomposes at 100° into dicyandiamide and benzyl mercaptan (Bernthsen a. Klinger, *B.* 12, 574).—$(CSN_2H_4C_7H_7Cl)_2PtCl_4$.

Compound with oxalic ether $(CSN_2H_4)_2Et_2C_2O_4$. [150°]. Monoclinic crystals (Nencki, *B.* 7, 780). Decomposed by hot water.

Compounds with amines $(CSN_2H_4)_4NMeH_3Br$. [138°]. Formed from methylamine hydrobromide and thio-urea in alcohol (Reynolds, *C. J.* 59, 392). Felted crystals.—$(CSN_2H_4)_3NEt_2H_2Br$. [134°]. Formed by boiling thio-urea together with diethylamine hydro-bromide and absolute alcohol.—$(CSN_2H_4)_3NEt_3HBr$.—$(CSN_2H_4)_2NEt_4I$ [135°]. Prisms.—$(CSN_2H_4)_2NEt_4Br$ [160°]. Rectangular prisms (Reynolds, *C. J.* 59, 388).

Acetyl derivative CSN_2H_3Ac. Mol. w. 118. [165°]. Formed by heating thio-urea with Ac_2O (Nencki, *B.* 6, 598). Formed also from thio-acetic acid and cyanamide (Prätorius, *J. pr.* [2] 21, 147). Prisms (from hot water), v. sol. alcohol, m. sol. ether.—$B'H_2PtCl_6$. Crystalline.

Propionyl derivative (Freytag, *J. pr.* [2] 20, 381).

Benzoyl derivative CSN_2H_3Bz. [170°]. Formed by warming thio-urea (2 mols.) with BzCl (1 mol.) (Pike, *B.* 6, 755). Got also from benzoyl sulphocyanide and NH_3Aq (Miguel, *Bl.* [2] 25, 252). Needles (from alcohol); sl. sol. cold water. Tastes bitter.

o-Oxy-benzoyl derivative $NH_2.CS.NH.CO.C_6H_4.OH$. [182°]. S. (boiling alcohol) 7. Formed from salicyl thiocarbimide and aqueous NH_3 (Miguel, *A. Ch.* [5] 11, 304).

THIO-ψ-URIC ACID *v.* THIO-URAMIDO-BARBITURIC ACID.

THIO-VALERIC ALDEHYDE $C_5H_{10}S$. (115°). Formed, together with $C_5H_8S_3$ [95°], by heating isovaleric aldehyde (23 pts.) with S (9 pts.) in sealed tubes at 250° for eight hours (Barbaglia, *G.* 11, 95; *B.* 17, 2654). Oil with penetrating odour like onions, sol. alcohol and ether. Does not combine with $NaHSO_3$.

Isomeride $C_5H_{10}S$. [69°]. V.D. $(H=1)$ 50·76. Formed by passing H_2S into a dilute aqueous solution of isovaleric aldehyde. Fibrous crystals (from ether), insol. water.

THIOXENE *v.* DI-METHYL-THIOPHENE.

THIOXYLENOL *v.* XYLYL MERCAPTAN.

THIOXYL METHYL KETONE *v.* DI-METHYL-THIENYL METHYL KETONE.

THORIUM Th. (*Thorinum.*) At. w. 232. Mol. w. unknown. The m.p. of Th has not been determined; it is certainly very high (Nilson, *B.* 15, 2541). S.G. 11·1 at 17° (N., *l.c.*, p. 2543). S.H. ·02787 (N., *B.* 16, 161). Crystallises in regular octahedral and hexagonal forms, isomorphous with Si (Brögger, *Z. K.* 7, 442; *cf.* Nilson, *B.* 15, 2546; 16, 162 *note*). S.V.S. 20·9.

Historical.—In 1818 Berzelius announced the discovery of the oxide of a new element in a rare Norwegian mineral; to the metal of this oxide he gave the name thorium (from the Scandinavian god *Thor*). A few years later Berzelius found that the substance he had supposed to be a new earth was really yttrium phosphate. In 1828, however, Berzelius isolated a new earth from another Norwegian mineral; he named the new earth thoria, and the mineral from which it had been prepared he called *thorite* (*P.* 16, 385). In 1851 Bergemann discovered a new metal and called it *donarium*; but this metal was shown to be identical with the thorium of Berzelius by Damour (*C. R.* 34, 685), Berlin (*P.* 87, 608), and Bergemann himself (*P.* 85, 558). In 1862 Bahr supposed he had found a new metal, which he called *wasium*, but soon afterwards he recognised that the metal was identical with thorium (*P.* 119, 572; 132, 227). The metal thorium was isolated by Berzelius in 1828 (*P.* 16, 385); it was also obtained by Chydenius in 1861 (*Bl.* [2] 1, 130); and in a state of greater purity by Nilson in 1882 (*B.* 15, 2537).

Occurrence.—Compounds of Th have been found only in very small quantities in a few localities. *Thorite* from Lövön in Norway contains c. 59 p.c. ThO_2 according to Berzelius; an orange-coloured variety of this mineral, *orangite*, was found by Bergemann to contain 74 p.c. ThO_2; Nilson (*B.* 15, 2519) found from 50 to 59 p.c. ThO_2 in different specimens of *thorite*. Small quantities of ThO_2 have been found in specimens of *pyrochlore*, *monazite*, *samarskite*, *euxenite*, *gadolinite*, and *orthite*. Several minerals containing Th have been discovered by Hidden a. Mackintosh in North Carolina and Colorado; one of these is a silicophosphate of Th, another a silicate of Th and Y, another a silicate of Th and U, and another is a uranate of Th, Pb, and Y (*Am. S.* [3] 36, 461; 38, 474).

Formation. — 1. By reducing $ThCl_4$ or $2ThCl_4.KCl$, by heating with K (Berzelius, *P.* 16, 385). — 2. By reducing fused $ThCl_4$, or $2ThCl_4.KCl$, by means of Na (Chydenius, *Bl.* [2] 1, 130; 6, 433; Nilson, *B.* 15, 2537).

Preparation.—Powdered *thorite* is evaporated with HClAq to dryness; the residue is heated to render silica insoluble, and treated with water; the solution is filtered and ppd. by H_2S; the filtrate from PbS is ppd. by NH_3Aq, and the pp. of crude $ThO_2.xH_2O$ is thoroughly washed and dissolved in HClAq; $Th(C_2O_4)_2$ is ppd. from this solution by $H_2C_2O_4Aq$, and the pp., after being thoroughly washed with boiling water, is decomposed by heating; the crude ThO_2 thus obtained is converted into $Th(SO_4)_2$ by treatment in a Pt basin with conc. H_2SO_4 after being thoroughly moistened with water. The impure $Th(SO_4)_2$ thus obtained is freed from acid and water by heating, and is dissolved in as little ice-cold water as possible (c. 5 parts are required), and the solution is heated to c. 20°, when $Th(SO_4)_2.9H_2O$ ppts. The $Th(SO_4)_2.9H_2O$ is dehydrated by heating; the $Th(SO_4)_2$ is dissolved in the minimum quantity of ice-cold water and the solution is heated to c. 20°; the crystals of $Th(SO_4)_2.9H_2O$ that separate are dehydrated, dissolved in ice-cold water, and the hydrated sulphate is ppd. by heating to 20°. This treatment is repeated a few times, when pure $Th(SO_4)_2.9H_2O$ is obtained. This method of purifying crude sulphate of Th, which is given by Nilson (*B.* 15, 2521), depends on the great differences between the solubilities in water of $Th(SO_4)_2$ and $Th(SO_4)_2.9H_2O$; the former, when pure, is soluble in 20·6 parts water at 0°, the latter requires 88 parts water at 0°, and much more at 20°, for solution. The sulphates of the metals present in the crude $Th(SO_4)_2$ prepared as described are much more soluble in water at 20° than $Th(SO_4)_2.9H_2O$. For other methods of preparing salts of Th from *thorite* *v.* Berzelius (*l.c.*), Chydenius (*l.c.*), Delafontaine (*Ar. Sc.* [2] 18, 343), and Cleve (*Bl.* [2] 21, 115).

To prepare Th from pure $Th(SO_4)_2$, Nilson (*B.* 15, 2538) dissolved the salt in water, ppd. by KOHAq and boiled, washed the $ThO_2.xH_2O$ thoroughly, dissolved in HClAq and reppd. by KOHAq (to remove all traces of H_2SO_4); he thoroughly washed the pp. by decantation, dissolved it in HClAq, added KCl, in the ratio $2ThCl_4:KCl$, evaporated to dryness in a Pt basin, and dried the residue by warming over a flame, stirring constantly, and then powdering and heating again. The dry double salt of $ThCl_4$ and KCl was heated to redness in a stream of dry HCl (prepared from conc. H_2SO_4 and sublimed NH_4Cl), HCl was removed by a stream of H, and some of the salt was transferred to a cylinder of wrought iron (fitted with a lid which screwed on), in which a layer of dry NaCl had been placed; pieces of sodium were arranged over the Th-K salt in the cylinder, on these was placed another layer of the Th-K salt, and the cylinder was thus nearly filled with alternate layers of Na and the double salt; the contents of the cylinder were pressed together by a piston which fitted into the cylinder, sufficient dry NaCl was added to fill the cylinder, the lid was screwed on, and the apparatus was heated to full redness for about fifteen minutes; after cooling, the contents of the apparatus were treated with cold water, whereby chlorides were dissolved and the excess of sodium was converted into NaOH and dissolved (the action is apt to be explosive); the thorium was washed with water, then with alcohol, and finally with ether, and dried at 100°.

The yield of thorium by this method is almost equal to that calculated from the equation. For a detailed description of the iron cylinder used for reduction *v.* Nilson a. Pettersson, *W.* 4, 554 (on the preparation of Be).

Properties.—Prepared as described, Th forms a greyish-white, glistening powder; the powder consists of small, thin, six-sided, crystalline leaflets; the larger crystals are as white and lustrous as silver, the smaller are grey and less lustrous. The crystals are somewhat brittle. S.G. at 17° 11·1 to 11·23; the latter number referring to the well-crystallised metal (Nilson, *B.* 15, 2543; 16, 160). S.H. (0° to 100°) ·02787, hence at. heat = 6·4 (N., *B.* 16, 161). Crystallises in combinations of regular octahedra and hexahedra; isomorphous with Si (N., *l.c.*, and *note*, p. 162). S.V.S. 20·9. The emission-spectrum of Th has been mapped by Thalén (*Détermin. des Longueurs d'Onde des Raies Métalliques* [Upsala, 1868]); the most marked lines are three in the indigo; 4393, 4382, and 4281. Soret (*Ar. Sc.* [2] 63, 59; [3] 4, 94) found that $ThCl_4Aq$ cuts off almost the whole of the ultra-violet part of the spectrum.

Th is unchanged in air up to 100°-120°; when heated to a higher temperature it burns to ThO_2 with production of much white light. Th is readily oxidised by heating in O; on this account some of the metal is oxidised in the process of preparation if the lid of the cylinder does not fit tightly. Nilson's experiments (*B.* 15, 2541) show that Th does not melt at the full heat of a wind-furnace. Th does not react with water; it combines directly with Cl, Br, I and S. The metal is slowly acted on by H_2SO_4 or HNO_3, rapidly by HClAq or *aqua regia*; alkali solutions do not seem to react.

The at. w. of Th has been determined: (1) by analysing $Th(SO_4)_2$ and hydrates of this salt (Berzelius, *P.* 16, 398 [1829]; Chydenius, *P.* 119, 43 [1861]; Delafontaine, *Ar. Sc.* 18, 343 [1863]; Hermann, *J. pr.* 93, 114 [1864]; Cleve, *Bl.* [2] 21, 116 [1874]; Nilson, *B.* 15, 2527 [1882]; Krüss a. Nilson, *B.* 20, 1665 [1887]); (2) by analyses of the double Th-K sulphate (Berzelius, *l.c.*); (3) by analyses of the acetate, oxalate, and formate of Th (Chydenius, *l.c.*); (4) by determining S.H. of Th (Nilson, *B.* 16, 153 [1883]); (5) by finding V.D. of $ThCl_4$ (Krüss a. Nilson, *B.* 20, 1665 [1887]). The mol. w. of Th is not known.

Th is distinctly metallic in its chemical relations; the only oxide that has been isolated with certainty, ThO_2, is basic, forming salts ThX_2 ($X = SO_4$, $2NO_3$, &c.). There are indications of the existence of a higher oxide (? Th_2O_7). Thorium forms the last member of the even-series family of Group IV. in the periodic classification of the elements. The members of this family are C, Ti, Zr, Ce, —, Th. The four elements Ti, Zr, Ce, and Th closely resemble one another in their chemical properties; they are also similar to the odd-series family of Group IV., namely, Si, Ge, Sn, —, Pb. For a general account of Group IV. (and more especially of C and Si) *v.* CARBON GROUP OF ELEMENTS (vol. i. p. 682); for a description of the even-series family (Ti, Zr, Ce, Th) *v.* TITANIUM GROUP OF ELEMENTS (this vol. p. 749); and for the odd-series family (Ge, Sn, Pb; Si being described in vol. i. p. 652) *v.* TIN GROUP OF ELEMENTS (this vol. p. 735).

The atom of thorium is tetravalent in the gaseous molecule $ThCl_4$.

Reactions and Combinations (Nilson, *B.* 15, 2541).—1. Heated in *air*, oxidation begins at c. 120°, and at much below red heat the metal burns brilliantly to ThO_2.—2. Heated in a stream of *oxygen*, the metal burns to ThO_2, with the production of dazzling white light.—3. Th burns to ThX_4 when heated in *chlorine*, in *bromine* vapour, or in vapour of *iodine*.—4. When heated with *sulphur* part of the S volatilises, and when the temperature is above the b.p. of S combination occurs with production of much light, ThS_2 being formed.—5. According to Troost (*C. R.* 116, 1227). Th combines with *carbon*, when ThO_2 is mixed with C and heated in CO_2 in the electric arc (*v. Carbide, infra*).—6. *Water* does not react with Th at any temperature, so far as experiments have been tried. Nilson (*l.c.*) gives no details, but says 'Thorium is not changed by water under any conditions.'—7. *Sulphuric acid* reacts slowly with Th; when dilute, the acid evolves H; when conc. and hot, SO_2 is given off.—8. The action of *nitric acid* is slight; the dilute warm acid acts very gradually; conc. acid is almost without action.—9. *Hydrochloric acid* rapidly dissolves Th, forming $ThCl_4$, and giving off H; the action is most complete with conc. acid.—10. *Aqua regia* dissolves Th easily.—11. *Alkaline solutions* seem not to react with Th.

Detection and Estimation.—Salts of Th are colourless when the acid is colourless. Alkalis, and also $(NH_4)_2SAq$, ppt. gelatinous, white $ThO_2.2H_2O$, insoluble in excess of the precipitant; alkali carbonates form a white pp. soluble in excess; solution in $(NH_4)_2CO_3Aq$ becomes turbid at 60°, but goes clear on cooling; saturation of a solution of a salt of Th with K_2SO_4 forms white $Th(SO_4)_2.K_2SO_4.2H_2O$, insoluble in K_2SO_4Aq, but soluble in water; K_4FeCy_6Aq ppts. white $ThFeCy_6$; oxalic acid and alkali oxalates ppt. white amorphous $Th(C_2O_4)_2$, insoluble in dilute acids, soluble in solutions of alkali oxalates or $NH_4.C_2H_3O_2$, especially on warming.

Th is generally estimated by ppn. as $ThO_2.2H_2O$ or $Th(C_2O_4)_2$, and subsequent conversion into ThO_2 by heating.

Thorium, bromide of. The gummy, white mass obtained by Berzelius (*P.* 16, 385), by evaporating a solution of $ThO_2.2H_2O$ in HBrAq, was probably $ThBr_4$. The *hydrated salt* $ThBr_4.10aq$ seems to have been obtained, from $ThO_2.2aq$, by Jannasch, Locke, a. Lesinsky (*Zeit. f. anorg. Chemie*, 5, 283).

Thorium, carbide of. By heating an intimate mixture of ThO_2 and C in the electric arc, in an atmosphere of CO_2, Troost (*C. R.* 116, 1227) obtained a hard, brittle solid, containing from 8·2 to 9·5 p.c. C, and therefore approximating to the formula ThC_2 (which requires 9·38 p.c. C). S.G. 10·15 at 15°; scratches glass slightly; decomposes cold water, giving off H and strongly smelling hydrocarbons; gradually decomposes in moist air; burns rapidly and brilliantly when heated to redness.

Thorium, chloride of, $ThCl_4$. Mol. w. 373·5. V.D. 172·2 at 1050°–1270° (Krüss a. Nilson, *B.* 20, 1671). This compound is formed by heating a mixture of ThO_2 and C in a stream of dry Cl; the $ThCl_4$ sublimes in white needles. Krüss a. Nilson (*B.* 20, 1675) prepared pure $ThCl_4$ by heating Th to incipient redness in a stream of dry, air-free HCl; then raising the temperature to full redness, in order to sublime a little $FeCl_2$, formed from the iron in the thorium used; and finally subliming the $ThCl_4$ at an incipient white heat. (For details of the apparatus used *v.* Nilson a. Pettersson, *J. pr.* [2] 33, 1 [on preparation of $BeCl_2$]).

$ThCl_4$ crystallises in lustrous, white needles; moderately hygroscopic, but remains some hours in the air before deliquescing (K. a. N., *l.c.*). Does not volatilise at c. 420° (Chydenius, *P.* 119, 43). The V.D. found by K. a. N. at temperatures from 1050° to 1270° shows that the formula $ThCl_4$ is molecular. K. a. N. got the value 142 for V.D. at 1400°, showing that dissociation had begun. Troost (*C. R.* 101, 360) obtained values for V.D. of $ThCl_4$ at c. 950° considerably lower than those of K. a. N. It is likely that his specimen was not pure, or that the apparatus used contained traces of O sufficient to cause decomposition to ThO_2 and Cl (K. a. N., *l.c.*, p. 1674).

Hydrated thorium chloride $ThCl_4.8H_2O$ was obtained by Cleve in thin, white prisms, by concentrating a solution of $ThO_2.2H_2O$ in HClAq, allowing to crystallise, and drying over H_2SO_4 (*Bl.* [2] 21, 116).

Double salts.—$ThCl_4$ combines with *potassium chloride* to form $2ThCl_4$, $KCl.18H_2O$; obtained by mixing very conc. solutions of the constituents. Forms small, white crystals; v. sol. water, also sol. alcohol; dehydrated by heating in HCl (Cleve, *Bl.* [2] 21, 116). By heating a dry mixture of $ThCl_4$ and NH_4Cl in HCl, Chydenius (*Bl.* [2] 1, 130; 6, 433) obtained a compound with *ammonium chloride*, which, when crystallised from water *in vacuo*, had the composition $ThCl_4.8NH_4Cl.8H_2O$; loses $6H_2O$ at 100°. Cleve (*l.c.*) prepared a compound with *platinic chloride* $ThCl_4.PtCl_4.12H_2O$; and Nilson (*l.c.*) a compound with *platinous chloride* $2ThCl_4.3PtCl_2.24H_2O$.

Thorium, ferrocyanide of, $ThFeCy_6.4H_2O$. A white powder; prepared by adding K_4FeCy_6Aq to solution of a salt of Th (Cleve, *Bl.* [2] 21, 116).

Thorium, fluoride of, $ThF_4.4H_2O$. Obtained by adding HFAq to $ThCl_4Aq$; the gelatinous pp. becomes powdery after a time (Chydenius, *Bl.* [2] 1, 130; 6, 433). Loses H_2O at 100°, and $2H_2O$ at 140°–200°; heated to redness gives ThO_2 and HF. Berzelius (*P.* 16, 385) obtained a heavy white powder by heating $ThO_2.2H_2O$ with HFAq. Combines with *potassium fluoride*; Chydenius (*l.c.*) obtained two salts, (1) $ThF_4.KF$ by mixing $ThCl_4Aq$ with KHF_2Aq, (2) $ThF_4.2KF.4H_2O$ by boiling $ThO_2.2H_2O$ with conc. KHF_2Aq and HFAq. The isolation of a third salt, $7ThF_4.8KF.6H_2O$, is doubtful.

Thorium, hydride of. By heating ThO_2 with excess of Mg powder, in a stream of H, Winkler (*B.* 24, 885) obtained a grey powder, which gave off H with dilute HClAq, and burnt when heated in O. Analyses of this powder gave 72·86 p.c. Th, ·50 p.c. H, 17·57 p.c. Mg, and 9·07 p.c. O. Supposing the ThO_2, Mg, and H interacted in accordance with the equation $ThO_2 + 2Mg + 2H = ThH_2 + 2MgO$, then, from the quantities of ThO_2 and Mg used, the product would give on analysis 73·77 p.c. Th, ·63 p.c. H, 15·45 p.c. Mg, and 10·15 p.c. O. From these data Winkler concluded that a hydride, ThH_2, was formed in the reaction.

Thorium, hydroxides of, *v.* OXIDES AND HYDRATED OXIDES (*infra*).

Thorium, iodide of. The white gummy mass, crystallising after a time, obtained by Chydenius (*Bl.* [2] 1, 130; 6, 433) by evaporating a solution of $ThO_2.2H_2O$ in HIAq, was probably ThI_4. The substance goes brown in the light.

Thorium, nitride of. By heating ThO_2 or $ThCl_4$ in NH_3, also by heating $ThCl_4$ and NH_4Cl in HCl, Chydenius (*l.c.*) obtained a small quantity of what he supposed to be either a nitride of Th or a compound of the metal with N and H.

Thorium, oxides and hydrated oxides of. Besides the oxide ThO_2 a peroxide, probably Th_2O_7, is said to exist.

THORIUM DIOXIDE ThO_2. (*Thoria.*) Mol. w. not known. Obtained by ppg. a salt of Th by alkali, $(NH_4)_2SAq$, or KCNAq, drying, and strongly heating; also by decomposing $Th(C_2O_4)_2$ by heat. A fine, white powder. S.G. 10·22 at 17° (Nilson, *B.* 15, 2536). S.V.S. 25·87. S.H. (0° to 100°) ·0548 (N. a. Pettersson, *B.* 13, 1459). By heating ThO_2 with borax in a porcelain oven, Nordenskjöld obtained the oxide in microscopic crystals isomorphous with SnO_2 and ZrO_2 (*P.* 150, 219). ThO_2 has not been fused; it is not reduced by heating with C, but when mixed with C and heated in Cl the chloride $ThCl_4$ is obtained. ThO_2 does not react with molten alkalis. It is scarcely acted on by acids; warm conc. H_2SO_4, however, converts it into $Th(SO_4)_2$.

HYDRATES OF THORIUM DIOXIDE. The *dihydrate* $ThO_2.2H_2O$ (= ThO_4H_4, *thorium hydroxide*) is obtained by ppg. a solution of a salt of Th by an alkali, $(NH_4)_2SAq$, or KCNAq, washing, and drying at 100°. It forms a hard, white solid. $ThO_2.2H_2O$ combines with CO_2 in the air; it dissolves in acids, forming salts ThX_2, where X $= SO_4$, $2NO_3$, &c. Another hydrate, $4ThO_2.H_2O$ ($= Th_4O_7(OH)_2$, *thorium metahydroxide*) is obtained, according to Cleve (*Bl.* [2] 21, 116), by heating ThO_2 (obtained by decomposition of $Th(C_2O_4)_2$) with excess of HNO_3Aq or HClAq at 100° till the acid is driven off, adding water, and then ppg. the opalescent solution so obtained by NH_3Aq, washing, and drying at 100°. This hydrate is said to be insoluble in dilute acids.

THORIUM PEROXIDE Th_2O_7. An oxide with this composition is said to be produced by adding H_2O_2Aq and NH_3Aq to a solution of a salt of Th (Cleve, *Bl.* [2] 43, 53; Lecoq de Boisbaudran, *C. R.* 100, 605).

Thorium, oxysulphide of. By strongly heating ThO_2, obtained from $ThO_2.2H_2O$, in CS_2 vapour, Chydenius (*Bl.* [2] 1, 130; 6, 433) obtained a solid substance to which he gave the formula $2ThO_2.ThS_2 = Th_3O_4S_2$. According to Krüss a. Volk (*Zeit. f. anorg. Chemie*, 5, 75; 6, 49), the compound obtained by heating ThO_2 in CS_2 is ThOS, and the same compound is formed by heating $2ThCl_4.KCl$ in H_2S.

Thorium, phosphide of. By heating Th in vapour of P, Berzelius (*P.* 16, 385) obtained a dark grey, metal-like, lustrous solid, which was changed to Th phosphate by heating in air.

Thorium, platinocyanide of, $Th(PtCy_4)_2.16H_2O$. Yellow-green, orthorhombic prisms (Cleve, *Bl.* [2] 21, 116).

Thorium, salts of. All the normal compounds which have been isolated by replacing H of acids by Th belong to the class ThX_2, where $X = 2NO_3$, $2IO_3$, SO_4, SO_3, $\frac{2}{3}PO_4$, &c.; basic salts also exist. The chief salts of oxyacids are *borate*, *carbonate*, *chlorate*, *chromate*, *iodate* and *periodate*, *molybdate*, *nitrate*, *oxalate*, *phosphates*, *selenate* and *selenites*, *silicates*, *sulphate* and *sulphite*, and *tartrate*.

Thorium, silicofluoride of. By treating $ThO_2.2H_2O$ with H_2SiF_6Aq, Cleve (*Bl.* [2] 21, 116) obtained a semi-transparent, crystalline solid, probably $Th(SiF_6)_2$; insol. in excess of H_2SiF_6; over H_2SO_4 gave off HF and SiF_4.

Thorium, sulphide of, ThS_2. Obtained by heating Th with S; excess of S sublimes, and when the temperature passes the b.p. of S the elements combine with evolution of heat and light (Nilson, *B.* 15, 2542; *cf.* Berzelius, *P.* 16, 385). Also formed by heating ThO_2, obtained from $Th(C_2O_4)_2$, to white heat in vapour of CS_2 (Chydenius, *Bl.* [2] 1, 130; 6, 433); but, according to Krüss a. Volk (*l.c.*), the compound thus formed is ThOS. A black powder. Burns when heated in air, giving off SO_2 and leaving

ThO_2. Not acted on by HClAq or HNO_3Aq; *aqua regia* dissolves the compound, forming $Th(SO_4)_2$. Molten KOH forms K_2S and ThO_2; heating in Cl produces $ThCl_4$.

Thorium, sulphocyanide of. The salt [? $Th(SCy)_4$] is obtained, as a viscid mass, by evaporating a solution of $ThO_2.2H_2O$ in HSCNAq. A solution of the compound gives a pp. with $HgCy_2$, said to be $Th(OH)_2SCy.HgCy_2.H_2O$; and the filtrate is said to give crystals of $Th(OH)(SCy)_3.3HgCy_2.12H_2O$ (Cleve, *Bl.* [2] 21, 116). M. M. P. M.

THUJIGENIN $C_{14}H_{12}O_7$ or $C_{28}H_{24}O_{14}$. Occurs in small quantity in *Frondes Thujæ*, the green parts of *Thuja occidentalis* (Rochleder a. Kawalier, *Sits. W.* 29, 10). Minute needles, v. sl. sol. water, sol. alcohol. NH_3 colours its alcoholic solution green. AcCl forms resinous $C_{14}H_{11}AcO_7$.

THUJIN $C_{20}H_{22}O_{12}$. Occurs in the green branches of *Thuja occidentalis* (Rochleder a. Kawalier, *Sits. W.* 29, 10). Minute lemon-yellow four-sided tables, sol. alcohol. Tastes bitter. Its alcoholic solution is coloured yellow by alkalis, is turned reddish-brown by air, gives a yellow pp. with lead acetate, and gives a dark-green colour with $FeCl_3$. Reduces ammoniacal $AgNO_3$. Boiling dilute H_2SO_4 turns it first green, then yellow, and splits it up into sugar and thujetin. Boiling baryta-water hydrolyses it in like manner.

Thujetin $C_{28}H_{28}O_{16}$. Yellow solid, nearly insol. water, sol. alcohol and ether. Not altered by dilute HCl or H_2SO_4. Its alcoholic solution is turned a splendid bluish-green colour by NH_3Aq. Gives, in alcoholic solution, a red pp. with lead acetate, and a black colour with $FeCl_3$. Boiling baryta-water converts it into thujetic acid $C_{28}H_{22}O_{13}$, which crystallises in minute lemon-yellow needles, sol. alcohol and ppd. by water.

(β)-THUJOL is Tanacetone.

THUJONE $C_{10}H_{16}O$. (212°). S.G. ^{22} ·9265. Occurs, together with the terpene $C_{10}H_{16}$ and lævorotatory fenchone, in the essential oil of thuja obtained by distilling the ends of the branches and the leaves of *Thuja occidentalis* with water (Schweizer, *A.* 51, 398; Jahns, *Ar. Ph.* 221, 748; Wallach, *A.* 272, 109). Yields an oxim.

Reactions.—1. When heated with *ammonium formate* it yields a formyl derivative which on saponification gives rise to 'thujoneamine' $C_{10}H_{17}.NH_2$ (199°), which forms the salts $B'_2H_2PtCl_6$ and B'HCl. Thujone-amine hydrochloride decomposes on distillation into NH_4Cl and thujene $C_{10}H_{16}$ (c. 173°), S.G. ^{20} ·84.—2. $KMnO_4$ forms two 'thujaketonic acids.'—3. Br forms $C_{10}H_{13}Br_3O$ [122°] (Wallach, *A.* 275, 179).

(α)-Thujaketonic acid $C_{10}H_{16}O_3$ *i.e.* $CH_3.CO.C_7H_{12}.CO_2H$. [76°]. S. c. 2·5 at 100°. Transparent plates. Yields an oxim [c. 186°].

(β)-Thujaketonic acid $C_7H_{12}(CO.CH_3).CO_2H$. [79°]. S. 1·43 at 100°. Small matted needles. On distillation it yields methyl heptyl ketone (186°) S.G. ^{20} ·854, which gives ψ-cumene dihydride C_9H_{14} on heating with $ZnCl_2$ at 100° (Wallach, *A.* 275, 166). Forms an oxim [106°] which crystallises in needles.—AgA': v. sl. sol. cold water.

THULIUM. This name was given by Cleve in 1879 to the metal of a new earth which he announced to be present in specimens of *gadolinite* (*C. R.* 89, 478). The name thulium was derived from *Thule*, the old name for Scandinavia. The presence of the new earth was more or less confirmed by the work of Nilson (*B.* 13, 1433), and of Soret (*C. R.* 89, 251). In 1880 Cleve said he had isolated *thulia*, and described it as a white earth, giving an emission spectrum characterised by two bright lines 5896 and 5306, and forming solutions of salts which showed two absorption bands 6840 and 4645. To this earth Cleve assigned the formula Tm_2O_3, and he determined the maximum value of the atomic weight of the supposed element to be Tm = 170·7. In 1888 Krüss a. Nilson declared that thulium consists of two distinct elements (*B.* 21, 1681).

The absolute homogeneity of thulia has been by no means established (*v.* Metals, rare, vol. iii. p. 245). M. M. P. M.

THYME OIL. The essential oil from garden thyme, *Thymus vulgaris*, contains lævorotatory thymene $C_{10}H_{16}$ (160°–165°), thymol $C_{10}H_{14}O$ and a little cymene (Lallemand, *A.* 102, 119; *A. Ch.* [3] 49, 155). The oil from wild thyme, *Thymus serpyllum*, contains cymene, thymol, carvacrol, and a phenol coloured violet by $FeCl_3$ (Jahns, *Ar. Ph.* [3] 16, 277; Febre, *C. R.* 92, 1290; Buri, *Ar. Ph.* [3] 12, 485).

THYMO-ACRYLIC ACID *v.* Oxy-cymyl-acrylic acid.

THYMOHYDROQUINONE *v.* Hydrothymoquinone.

THYMOL $C_{10}H_{14}O$ *i.e.* $C_6H_3MePr.OH$ [5:2:1]. Mol. w. 150. V.D. 75·3 (calc. 75) (Eykman, *B.* 22, 2757). [49·5°] (Reissert, *B.* 23, 2242). (232°). S.G. $\frac{0}{0}$ ·9941. C.E. (0°–10°) ·00085. S. ·3. S.V. 188·9 (Pinette, *A.* 243, 46); 189·3 (Ramsay). $R_\infty = 76·56$ (Nasini a. Bernheimer, *G.* 15, 93). H.F.p. (liquid) 69,250; (solid) −3768. Occurs in essential oil of thyme (Doveri, *A.* 64, 374; Lallemand, *A. Ch.* [3] 49, 148; *A.* 102, 119), of horsemint, *Monarda punctata* (Arppe, *A.* 58, 42), of *Ptychotis ajowan* (Stenhouse a. Haines, *A.* 98, 307; H. Müller, *B.* 2, 130) of *Monarda Didyma*, of *Ammi Copticum* (Buri, *Ar. Ph.* [3] 12, 485), and in the oil from wild thyme (Jahns, *B.* 15, 819).

Formation.—By boiling diazo-*n*-cymene with water (Widman, *B.* 15, 170; 19, 245).

Preparation.—By extracting oil of thyme with NaOHAq, ppg. by HCl, and recrystallising from HOAc.

Properties.—Plates (from alcohol), v. sol. alcohol, ether, and HOAc, v. sl. sol. water. Has a slight odour of thyme and a peppery taste. When solid it is slightly heavier than water, when liquid it is lighter. Not ppd. by adding water to its alcoholic solution. Not dissolved by NH_3Aq, but absorbs NH_3, becoming liquid, but re-solidifying after the NH_3 has escaped. Sol. KOHAq. $FeCl_3$ does not colour its aqueous solution. Bromine-water only gives a milkiness. An aqueous solution (1 vol.) warmed first with HOAc (½ vol.) and then with H_2SO_4 (1 vol.) is coloured reddish-violet, the solution showing two absorption bands at E and D (Wolff, *Fr.* 22, 96). KOHAq followed by I in KI gives on warming a fugitive red tint (Itallie, *Fr.* 29, 205).

Estimation: Messinger, *B.* 23, 2754.

Reactions.—1. Decomposed by distilling with P_2O_5 into propylene and *m*-cresol.—2. P_2S_5 yields cymene (Fittica, *B.* 6, 938; *A.* 172, 305). 3. Oxidised by *chromic acid* to thymoquinone.—4. PCl_5 yields chloro-cymene. — 5. *Potash-fusion* yields several oxy-acids (Barth, *B.* 11, 567, 1571).—6. *Iodine* and *potash* yield a red amorphous pp. [110°] converted by heat or by boiling water into a yellow body [165°] (Messinger a. Vortmann, *B.* 22, 2316).—7. Boiling $POCl_3$ (1 mol.) acting on thymol (1 mol.) forms liquid $C_{10}H_{13}O.POCl_2$ (280°-285°) which is converted by water into liquid $C_{10}H_{13}O.PO(OH)_2$, which yields BaA'' 4aq and is decomposed by heat into thymol and HPO_3 (Discalzo, *G.* 15, 279).—8. Boiling $POCl_3$ acting on thymol (2 mols.) forms $(C_{10}H_{13}O)_2POCl$ (330°-340° at 320 mm.), a liquid which is converted by water into $(C_{10}H_{13}O)_2PO.OH$, which is insol. water and yields NaA' [74°] (Kreysler, *B.* 18, 1705) and BaA'_2 5aq. S. ·197 at 21°.—9. PCl_5 (1 mol.) acting on thymol (4 mols.) forms $(C_{10}H_{13}O)_3PO$ [59°] crystallising from alcohol in prisms (E. a. L.).—10. $SiCl_4$ forms $Si(OC_{10}H_{13})_4$ [48°] (450°) crystallising from $CHCl_3$ in prisms (Hertkorn, *B.* 18, 1693).—11. $Cl.CO.NH_2$ reacts forming $C_6H_3MePr.O.CO.NH.CO.NH_2$ [190°] (Gattermann, *A.* 244, 44).—12. $C_6H_4(NMe_2)(NH_2)$ [1:4] forms indothymol $C_6H_4(NMe_2).N{<}\genfrac{}{}{0pt}{}{C_6H_2MePr}{O}$ [69·5°] crystallising in needles, insol. water and alkalis, forming a blue solution in alcohol, a violet in ether, and a green in HOAc. HClAq decomposes indothymol into thymoquinone, dimethyl-aniline, and NH_3 (Bayrac, *Bl.* [3] 7, 97). 13. *Chloral* forms $C_{10}H_{11}OC_2HCl_3O$ [130°-134°] (Mazzara, *G.* 13, 272).—14. *Chloral*, conc. H_2SO_4, and HOAc yield $CCl_3.CH(C_{10}H_{12}.OH)_2$ (Jäger, *B.* 7, 1197).—15. Dilute H_2SO_4 gradually added to a mixture of benzoic aldehyde (1 mol.) and thymol (2 mols.) forms $C_6H_5.CH(C_{10}H_{12}.OH)_2$ [146°] which is sol. alkalis and yields a diacetyl derivative [126°] (Russanoff, *B.* 22, 1943).—16. $COCl_2$ passed into an aqueous solution of $C_{10}H_{13}ONa$ forms di-thymyl carbonate $(C_{10}H_{13}O)_2CO$ which crystallises from alcohol in needles [48°] (above 360°) and yields *o*-oxybenzoic acid when heated with NaOPh at 180° (Richter, *J. pr.* [2] 27, 505). According to Bender (*B.* 19, 2268), di-thymyl carbonate, prepared by heating thymyl ethyl carbonate at 300°, melts at 60°. $COCl_2$ also forms, as a by-product, $C_{10}H_{13}O.COCl$, which is converted by ammonia into $C_{10}H_{13}O.CO.NH_2$ [131°].—17. $Cl.CO_2Et$ acting in the cold upon $C_{10}H_{13}ONa$ forms $C_{10}H_{13}O.CO.OEt$ (c. 261°), an oil which yields *o*-oxy-benzoic acid, PhOEt, and thymol when heated with NaOPh (Richter).—18. Treatment with $ClCH_2.CO_2H$ and NaOHAq produces $C_{10}H_{13}O.CH_2.CO_2H$ [148°] which yields BaA'_2 2aq, PbA'_2, AgA', oily EtA' (290°), and an amide [97°] (Saarbach, *J. pr.* [2] 21, 159; Spica, *G.* 10, 342). 19. *a-Chloropropionic acid* and KOHAq yield $C_{10}H_{13}O.CHMe.CO_2H$ [48°] (Scichilone, *G.* 12, 50).—20. Thymol (10 g.) mixed with H_2SO_4 (70 g.) containing nitrous acid gives thymolchroïn $C_{40}H_{52}N_2O_5$, a dark-violet amorphous body which dissolves in alcohol, ether, $CHCl_3$, and benzene, forming red solutions with pale-green fluorescence. Alkalis turn its alcoholic solutions blue. Sublimes at 140°, giving off violet vapours. Yields brown amorphous $C_{40}H_{48}Ac_4N_2O_5$ (Brunner a. Chuit, *B.* 21, 252; *cf.* Liebermann, *B.* 7, 1100).—21. By heating with ammonium-zinc chloride it is converted into thymylamine $C_{10}H_{13}NH_2$ and di-thymylamine $(C_{10}H_{13})_2NH$.—22. *Cyanuric chloride* converts sodium thymol into $(C_{10}H_{13})_3C_3N_3O_3$ [151°] a yellow crystalline powder, insol. water, sl. sol. alcohol (Otto, *B.* 20, 2239).—23. Aqueous KOH and $K_2S_2O_7$ form $C_{10}H_{13}O.SO_2.OK$, which crystallises from alcohol in slender silky threads (Heymann a. Königs, *B.* 19, 3307). It is oxidised by alkaline $KMnO_4$ to oxycuminic acid $C_6H_3Pr(OH).CO_2H$ [4:3:1].

S a l t s. — $C_{10}H_{13}ONa$. Crystalline. Its aqueous solution is ppd. by $HgCl_2$ and $AgNO_3$.—$C_{10}H_{13}O.Hg.HgNO_3$.—$C_{10}H_{13}O.Hg.HgOAc$ (Merck, *G. P.* 48539; *Pharm. Zeit.* 1889, 625).—$(C_{10}H_{13}O)_2Hg_2O$ (Lallemand).—$(C_{10}H_{13}O)_3Al$. Decomposed by heat into propylene and $(C_6H_4Me.O)_3Al$, the *m*-cresylate then splitting up into alumina, *m*-cresol, di-*m*-tolyl oxide, and a body $C_{15}H_{14}O$ [200°] S. (alcohol) ·17 at 20°; 1 at 78°; S. (benzene) ·93 at 21°; S.G. 805; V.D. 208·8, crystallising in pearly plates (Gladstone a. Tribe, *C. J.* 39, 9; 41, 11).

Acetyl derivative $C_{10}H_{13}OAc$. (245°). S.G. $\frac{0}{0}$ 1·009.

Benzoyl derivative $C_{10}H_{13}OBz$. [32°]. H.F. 90,480 (Stohmann, *J. pr.* [2] 36, 9).

Methyl ether $C_{10}H_{13}OMe$. (216° cor.). S.G. $\frac{0}{0}$ ·9531. C.E. (0°-10°) ·00083. S.V. 214·3 (Pinette, *A.* 243, 47). H.F.p. 61,429 [C,O_2 = 94,000; H_2,O = 69,000] (Stohmann, *J. pr.* [2] 35, 26). Formed from thymol, KOH, and MeI (Engelhardt a. Latschinoff, *Z.* [2] 5, 43).

Ethyl ether $C_{10}H_{13}OEt$. (227°) (Pinette; *cf.* Jungfleisch, *Bl.* [2] 4, 17). S.G. $\frac{0}{0}$ ·9334. C.E. (0°-10°) ·00089. S.V. 240. H.F.p. 68,858 (Stohmann). Yields the ethyl derivative of oxyterephthalic acid on oxidation (Paterno a. Canzoneri, *G.* 9, 460). Decomposes at 360°-400° into thymol and ethylene (Bamberger, *B.* 19, 1820).

Propyl ether $C_{10}H_{13}OPr$. (243°). S.G. $\frac{0}{0}$ ·9276. C.E. (0°-10°) ·00088. S.V. 265·5.

Butyl ether $C_{10}H_{13}OC_4H_9$. (258°). S.G. $\frac{0}{0}$ ·9230. C.E. (0°-10°) ·00085. S.V. 289·2.

Isoamyl ether $C_{10}H_{13}OC_5H_{11}$. (238°-243°) (E. a. L.). Oil.

Heptyl ether $C_{10}H_{13}OC_7H_{15}$. (307°). S.G. $\frac{0}{0}$ ·9097. C.E. (0°-10°) ·00082. S.V. 368·7.

Octyl ether $C_{10}H_{13}OC_8H_{17}$. (320°). S.G. $\frac{0}{0}$ ·9026. C.E. (0°-10°) ·00075. S.V. 395·6 (Pinette).

Ethylene ether $(C_{10}H_{13}O)_2C_2H_4$. [99°]. Plates (from ether) (Paterno, *G.* 5, 13).

Nitroso-thymol *v.* *Oxim* of Thymoquinone.

Dithymol *v.* Di-oxy-dicymyl.

References.—*Amido-*, Bromo-amido-, Bromo-nitro-, Tri-chloro-, Iodo-, Iodo-amido-, and Nitro-thymol.

DI-THYMOL-ETHANE *v.* Di-oxy-di-cymyl-ethane.

THYMOL DICARBOXYLIC ALDEHYDE $C_{12}H_{14}O_3$ *i.e.* $C_6HMePr(OH)(CHO)_2$. [80°]. Formed as a by-product in the preparation of thymotic acid by the action of chloroform and NaOH on thymol (Kobek, *B.* 16, 2104). Needles. Gives a red colour with $FeCl_3$.

THYMOL (α)-SULPHONIC ACID $C_6H_2MePr(OH).SO_3H$. [92°] (Stebbins, *Am.* 3, 111). Formed from thymol by the action of

H_2SO_4 or $Cl.SO_2.OH$ at 50° (Engelhardt a. Latschinoff, *Z.* 1869, 44; 1871, 261). Pearly plates (containing aq), v. e. sol. water. $FeCl_3$ colours neutral solutions dark-violet. Yields thymoquinone on oxidation.

Salts.—KA' 2½aq. Efflorescent tables, v. e. sol. water.—NaA' 2½aq. [167°].—NH_4A' 2aq. [172°].—CaA'_2 2aq. [157°].—BaA'_2 4aq. Prisms, decomposing at 100°.—PbA'_2 4aq.

Benzoyl derivative $C_{10}H_{12}(OBz).SO_3H$. —KA' 2aq.—CaA'_2 4aq.—BaA'_2 5aq.—PbA'_2 5aq.

Ethyl derivative $C_{10}H_{12}(OEt)SO_3H$. Formed from the K salt, KOH, and EtI.—KA'. Thin plates.—BaA'_2 3aq. Plates, sl. sol. hot Aq.

Isoamyl derivative $C_{10}H_{12}(OC_5H_{11}).SO_3H$. —KA'. Needles, v. sol. water.—BaA'_2 3aq.

Thymol (β)-sulphonic acid $C_{10}H_{12}(OH).SO_3H$. Formed in small quantity by the action of H_2SO_4 on thymol.—KA'aq. Plates, sl. sol. cold water. Coloured violet-blue by $FeCl_3$.

Thymol (γ)-sulphonic acid $C_{10}H_{12}(OH).SO_3H$. Formed by heating thymol with fuming H_2SO_4 at 100° (E. a. L.).—KA'aq. Granular, v. sol. water.—$BaA'_2$3aq. Tufts of needles, more soluble than the (α)-isomeride. Not decomposed at 120°.

Benzoyl derivative $C_{10}H_{12}(OBz).SO_3H$.—KA' 3aq. Flat needles, sl. sol. cold water.

Ethyl derivative $C_{10}H_{12}(OEt).SO_3H$.—KA'. Flat needles.—BaA'_2 3aq. Six-sided tables.

Thymol-sulphonic acid

Ethyl derivative $C_6H_2MePr(OEt)SO_3H$ [1:4:3:6]. Formed by boiling diazo-cymene-sulphonic acid with absolute alcohol.—BaA'_2 3aq: white plates, sol. hot water, sl. sol. cold (Widman, *B.* 19, 247).

Thymol sulphonic acid. *Methyl derivative* $C_{10}H_{12}(OMe).SO_3H$. Formed, together with an isomeride, by sulphonation of the methyl ether of thymol (E. a. L.; Paterno a. Pisati, *B.* 8, 440).—KA': large tables.—$BaA'_2$3aq. Nodules, v. sol. hot water. S. 3·94 at 26°.

Thymol disulphonic acid $C_{10}H_{11}(OH)(SO_3H)_2$. Formed by sulphonating thymol.—K_2A'' 1½aq. Efflorescent needles (from alcohol), v. e. sol. water.

References. — AMIDO-, BROMO-, and IODO-THYMOL SULPHONIC ACID.

THYMOQUINONE $C_{10}H_{12}O_2$ *i.e.* $C_6H_2MePrO_2$ [2:5:4:1]. Mol. w. 164. [45·5°]. (232°). Formed by oxidation of thymol (Lallemand, *J.* 1854, 592), of the methyl ether of thymol (Paterno, *B.* 8, 440), of cymenol (Carstanjen, *J. pr.* [2] 3, 53; 15, 410), of di-oxy-di-cymyl-ethane (Steiner, *B.* 11, 289), of carvacrol *p*-sulphonic acid (Claus, *J. pr.* [2] 39, 356), and of amido-thymol (Andersen, *J. pr.* [2] 23, 172; Armstrong, *B.* 10, 297; Liebermann a. Ilinski, *B.* 18, 3194). Yellow crystals, with pungent odour, v. sl. sol. water, v. sol. alcohol and ether. Reduced by SO_2 to hydrothymoquinone. K_2SO_3 at 60° forms crystalline $C_{10}H_{13}O_5SK$. Phenyl cyanate forms $C_{10}H_{12}O:NO.CO.NHPh$ [132°], crystallising in large yellow needles (Goldschmidt a. Strauss, *B.* 22, 3106).

Oxim $C_6H_2MePrO(NOH)$ or $C_6H_2MePr(OH)(NO)$. *Nitroso-thymol.* [162°]. Formed by the action of nitrous acid on thymol (R. Schiff, *B.* 8, 1500; Widmann, *B.* 15, 170; Liebermann, *B.* 18, 3194). Formed also by the action of hydroxylamine hydrochloride on thymoquinone (Goldschmidt a. Schmid, *B.* 17, 2061). Slender monoclinic needles, *a:b:c* = 1·987:1:1·8941; β = 94° 57′ (Panebianco, *G.* 10, 78); sl. sol. hot water. Its alkaline solution is red. Oxidised by alkaline K_3FeCy_6 to nitro-thymol. Reduced by tin and HCl to amido-thymol (Liebermann, *B.* 10, 77). Does not react with SO_2 (Schmidt, *J. pr.* [2] 44, 521). Fuming HCl forms di-chloro-thymoquinone and chloro-amido-thymol (Sutkowski, *B.* 19, 2315). KOH and BzCl form $C_{10}H_{12}O(NOBz)$ [110°]. Hydroxylamine (3 mols.) in strongly alkaline solution forms, in 48 hours, a white substance which, if ppd. by HOAc, immediately dissolved in dilute NaOH, treated with an equal weight of a phenol, and exposed to the air, gives a deep-blue colour or pp. turned red by acids (Kehrmann a. Messinger, *B.* 23, 2818, 3557).

Di-oxim $C_{10}H_{14}N_2O_2$ *i.e.* $C_{10}H_{12}(NOH)_2$. Formed by boiling an alcoholic solution of nitroso-thymol (1 mol.) with hydroxylamine hydrochloride (2 mols.) and partially neutralising with alkali from time to time. Yellowish-white granules, decomposing at 235° without melting. Insol. water and NH_3Aq, sol. KOHAq.

Chlorimide $C_6H_2MePr<\genfrac{}{}{0pt}{}{O}{NCl}$. Formed by adding a solution of bleaching powder to a cold acidified solution of the hydrochloride of *p*-amido-thymol (Andresen, *J. pr.* [2] 23, 169). Pungent oil, volatilising even at 15°. Decomposes at 160°–170°. Volatile with steam. Decomposed by conc. HClAq into chloro-amido-thymol and mono- and di- chloro-thymoquinone. Conc. HBrAq behaves in a precisely similar way. Alcohol at 140° converts the chlorimide into thymoquinone. Conc. aqueous SO_2 reduces it in a few days to hydro-thymoquinone. Reduced by tin and HCl to *p*-amido-thymol, considerable quantities of hydrothymoquinone being formed at the same time.

Polymeride [201°]. Formed by the action of daylight on thymoquinone (Armstrong, *B.* 10, 297; Liebermann, *B.* 10, 2177; 18, 3193). Silky yellow needles (from alcohol), insol. ether. Changes to thymoquinone on distillation. Not attacked by SO_2 at 180°, but reduced by HI and P, or in alcoholic solution, by Zn and HClAq to hydrothymoquinone.

Phenyl hydrazide [249°]. Insol. benzene.

Oxim $(C_{10}H_{13}NO_2)_x$. [263°]. Crystalline, insol. water. Reduced by tin and HCl to amido-hydrothymoquinone.

Dioxim $(C_{10}H_{14}N_2O_2)_x$. [c. 290°]. Powder. May be reduced to di-amido-cymene.

References.—DI-AMIDO-, BROMO-, CHLORO-, IODO-, and OXY- THYMOQUINONE.

***o*-THYMOTIC ACID** $C_{11}H_{14}O_3$ *i.e.* $C_6H_2Me(C_3H_7)(OH).CO_2H$[6:3:2:1]. Mol. w. 194. [123°]. Formed by the action of CO_2 upon heated sodium-thymol (Kolbe a. Lautemann, *A.* 115, 205; Kobek, *B.* 16, 2101). Silky crystals, v. sol. alcohol, ether, and benzene, almost insol. cold water. Volatile with steam. Gives a deep-blue colour with $FeCl_3$. Yields thymol when distilled with baryta. PCl_5 acting on the Na salt forms thymotide $C_{11}H_{12}O_2$ [187°], which is reconverted into thymotic acid by potash fusion (Naquet, *Bl.* 4, 92).

***p*-Thymotic acid** $C_{11}H_{14}O_3$ *i.e.* $C_6H_2Me(C_3H_7)(OH).CO_2H$[6:3:4:1]. [157°]

Formed by heating thymol with aqueous NaOH and CCl_4 (Kobek). White plates, v. sol. alcohol, ether, and benzene, insol. cold water. Not coloured by $FeCl_3$.

Methyl derivative $C_6H_2Me(C_3H_7)(OMe).CO_2H$. [137°]. Silky needles (from dilute alcohol).—AgA′: pp.

p-**THYMOTIC ALCOHOL** $C_{11}H_{16}O_2$ *i.e.* $C_6H_2Me(C_3H_7)(OH).CH_2OH$. [120°–130°]. Formed by reducing thymotic aldehyde with sodium-amalgam (Kobek, *B.* 16, 2098). Amorphous powder, v. sol. alcohol and ether, insol. water.

p-**THYMOTIC ALDEHYDE** $C_{11}H_{14}O_2$ *i.e.* $C_6H_2Me(C_3H_7)(OH)CHO$[6:3:4:1]. [133°]. Formed, together with $C_6HMe(C_3H_7)(OH)(CHO)_2$ [6:3:4:5:1] [80°], by heating thymol with chloroform and NaOHAq (Kobek, *B.* 16, 2096). Silky needles, v. sol. alcohol, sl. sol. hot water. On heating with aniline it yields the compound $C_6H_2Me(C_3H_7)(OH).CH{:}NPh$ [142°] crystallising in yellow needles.

Methyl derivative $C_6H_2Me(C_3H_7)(OMe).CHO$. (278°). Formed by methylation of the aldehyde. Oil, yielding an anilide $C_6H_2Me(C_3H_7)(OMe).CH{:}NPh$ [80°] crystallising in transparent tables.

THYMYLAMINE $C_{10}H_{13}NH_2$. (230°). Formed, together with di-thymylamine, by heating thymol with ammoniacal $ZnBr_2$ or $ZnCl_2$ and NH_4Br or NH_4Cl at 350°-360°, the yield being 25 p.c. (Lloyd, *B.* 20, 1260). Colourless oil.—$B'_2H_2PtCl_6$: yellow needles.

Acetyl derivative $C_{10}H_{13}NAc$. [112°].

Isomeride *v.* CARVACRYLAMINE.

Di-thymyl-amine $(C_{10}H_{13})_2NH$. (340°–345°). Formed as above, the yield being 25 p.c. Oil. Its solution in P_2SO_4 is coloured blue by nitrites or nitrates.—$B'_2H_2PtCl_6$.

Acetyl derivative $(C_{10}H_{13})_2NAc$. [78°].

THYMYL CYANURIC ACID *v.* CYANIC ACID.

THYMYL MERCAPTAN $C_{10}H_{13}SH$. *Thiothymol.* (231°). S.G. ·989. Formed by heating thymol with P_2S_5 (Fittica, *A.* 172, 325; Bechler, *J. pr.* [2] 8, 167). Liquid with pungent odour. Oxidised by HNO_3 to sulpho-toluic acid. —$Hg(SC_{10}H_{13})_2$. Greenish rhombohedra [78°]. —PbA'_2: golden needles (from alcohol).

THYMYL PHOSPHATE $(C_{10}H_{13})_3PO_4$. [59°]. Formed by heating thymol with $POCl_3$, the yield being 75 p.c. of the theoretical amount (Kreysler, *B.* 18, 1705). Colourless needles.

THYMYL SILICATE $(C_{10}H_{13})_4SiO_4$. [48°]. (c. 450°). Formed by heating thymol with $SiCl_4$, the yield being 70 p.c. of the theoretical amount (Hertkorn, *B.* 18, 1692).

TIGLIC ACID $C_5H_8O_2$ *i.e.* $CH_3.CH{:}CMe.CO_2H$. *Methyl-crotonic acid.* Mol. w. 100. [65°]. (199° i.V.) (Kopp, *A.* 195, 84). Occurs as a glyceryl ether in croton oil (Geuther a. Fröhlich, *Z.* 1870, 549; Schmidt a. Berendes, *A.* 191, 94; *B.* 10, 835; *Ar. Ph.* [3] 13, 213), and as isoamyl ether in Roman oil of chamomile (Köbig, *A.* 195, 101).

Formation.—1. By the action of heat or of conc. H_2SO_4 on angelic acid (Demarçay, *B.* 9, 1933).—2. By reducing the dibromide of angelic acid with sodium-amalgam (Schmidt, *A.* 208, 253).—3. From $CEtMe(OH).CO_2Et$ (derived from oxalic ether, EtI, MeI, and Zn) by treatment with PCl_5 and saponification of the product (Frankland a. Duppa, *A.* 136, 9).—4. By distilling $CH_3.CH(OH).CHMe.CO_2H$ (Rohrbeck, *A.* 188, 235), or by heating it with HIAq (Rücker, *A.* 201, 61).—5. By reducing methyl-acetoacetic ether with sodium-amalgam and heating the resulting $CH_3.CH(OH).CHMe.CO_2H$ at 200° (Wislicenus, *A.* 250, 243).—6. By heating veratrine with alcoholic potash (Wright a. Luff, *C. J.* 33, 347).—7. By heating veratrine with conc. HClAq (Ahrens, *B.* 23, 2704).

Properties.—Triclinic plates, v. sol. hot water, alcohol, and ether. Smells like benzoic acid. Volatile with steam. Not attacked by sodium-amalgam. Forms with isovaleric acid the double salts $CaA'(C_5H_9O_2)\,4\frac{1}{2}aq$ and $AgA'C_5H_{10}O_2$.

Reactions.—1. Yields acetic aldehyde and acid on oxidation with $KMnO_4$ (Beilstein a. Wiegand, *B.* 17, 2261; Kondakoff, *J. R.* 20, 523).—2. *Potash-fusion* gives propionic and acetic acids.—3. Fuming HI forms an iodovaleric acid [87°] (Schmidt, *B.* 12, 252).—4. HI and P yield $CEtMeH.CO_2H$.—5. *Bromine* forms $C_5H_8Br_2O_2$ [88°] (Pückert, *A.* 250, 240; Wislicenus, *A.* 272, 21; 274, 99).—6. HOCl forms a mixture of $CH_3.CH(OH).CClMe.CO_2H$ [112°] and $CH_3.CHCl.CMe(OH).CO_2H$ [75°] (Melikoff, *Bl.* [2] 47, 166).

Salts.—KA′.—CaA'_2 3aq. S. (of CaA'_2) 6·4 at 17°.—BaA'_2 4aq. S. (of BaA'_2) 18·5 at 16°.—AgA′.

Ethyl ether EtA′. (155°). S.G. ^{9} ·942.

Isoamyl ether $C_5H_{11}A'$. (205°).

Reference.—*Chloro-tiglic acid.*

TIGLIC ALDEHYDE C_5H_8O. *Guaiol.* (118°). V.D. 2·92. Formed by distillation of gum guaiacum (Deville, *C. R.* 17, 1143; 19, 134; Völckel, *A.* 89, 346; Herzig, *M.* 3, 118). Formed also by heating acetic aldehyde (1 mol.) with propionic aldehyde (1 mol.) and aqueous (28 p.c.) NaOAc for 30 hours at 100° (Lieben a. Zeisel, *M.* 7, 53). Pungent oil, miscible with alcohol and ether. Oxidised by air to tiglic acid. Alkaline sodium nitroprusside gives a violet-red colour destroyed by HOAc (Von Bitto, *A.* 267, 376). Br forms di-bromo-valeric aldehyde. Iron and dilute (50 p.c.) acetic acid reduce it to valeric aldehyde (91°), an inactive amyl alcohol $CHMeEt.CH_2OH$ (129°) and tiglic alcohol $C_5H_{10}O$ (c. 130°). Reacts with phenyl-hydrazine, and combines with $NaHSO_3$. CrO_3 forms acetic acid (Gilm, *A.* 106, 379). Aqueous SO_2 at 0° forms oxy-pentane disulphonic acid (Haymann, *M.* 9, 1055).

TIGLYL ALCOHOL *v.* PENTENYL ALCOHOL.

TIN Sn. At. w. 118·8 (*v. infra*). Mol. w. not known with certainty (*v. infra*). Melts at 231·68° (Callendar a. Griffiths, *C. N.* 63, 1); for other data, giving m.p. from 220° to 235°, *v.* Carnelley's *Melting and Boiling-point Tables* (2, 12). Boils between the m.p.s of Ni and Fe, *i.e.* between 1450° and 1600° (Carnelley a. Williams, *C. J.* 35, 566). S.G. c. 7·3 (determinations vary from c. 7·0 to c. 7·5) (*v.* Clarke's *Table of Specific Gravities* [2nd ed.] 5). The so-called allotropic variety of tin seems to have S.G. from 5·8 to 6·1 (*v.* Schertel, *J. pr.* [2] 19, 322). S.H. (0°–100°) ·0559; so-called allotropic tin has S.H. ·0545 (0°–100°) (Bunsen, *P.* 141, 1); S.H. liquid tin (250°–350°) = ·0637 (Person, *A. Ch.* [3] 24, 129). C.E. (linear, 0°–100°) ·00002296 (Matthiessen, *Pr.* 15, 220; *v.* also Kopp, *A.* 81, 1; Fizeau, *C. R.* 68, 1125). T.C. 15·2 (Ag = 100) (Wiedemann, *P. M.* [4] 19, 243). E.C. (Hg at 0° = 1) at 15° = 8·823 (Kirchoff a. Hausemann, *W.* 13, 406); at 0° = 8·726, at 100° = 6·091 (Lorenz, *W.* 13, 422). Heat of fusion (for 1 kilo. tin) = 14,252 (Person, *A. Ch.* [3] 24, 129). For spectrum of tin *v.* Thalén (*A. Ch.* [4] 18, 237); Salet (*C. J.* [2] 9, 1147); also Hartley a. Adeney (*T.* 1884 [i.] 113).

Historical.—Tin was known long before the Christian era. Pliny distinguished *plumbum album* or *candidum* from *plumbum nigrum*; in the fourth century A.D. the former of these substances began to be called *stannum*, from which word the symbol Sn is derived.

Occurrence.—Tin has been found in Siberia and in South Australia. *Tinstone* or *cassiterite*, consisting essentially of SnO_2, is found in considerable quantities, both in veins and in alluvial deposits, in many parts of the world. *Tin pyrites*, containing SnS_2 with Cu_2S, FeS, and ZnS, is found in small quantities in various tin veins. Small quantities of SnO_2 occur in various *lithia-micas* (Sandberger, *J. M.* 1878. 291, 657). According to Lockyer (*Pr.* 27, 279), there are indications of the occurrence of tin in the sun.

Formation.—1. By ppn. from solution of $SnCl_2$ in HClAq by tin; or by tin and iron simultaneously, with a little Fe_2O_3 to neutralise excess of acid (Schultze, *B.* 23, 974).—2. By electrolysis of $SnCl_2$ in dilute HClAq.—3. By reduction of SnO_2 by heating with C.

Preparation.—Tinstone is cleansed by agitation with water; it is then sorted, stamped or rolled to a certain fineness, and washed. The washed ore is calcined in reverberatory calciners to remove sulphur from the sulphides of Fe that are present in most tin ores; the calcined ore is exposed to the air for some days to insure the oxidation of any sulphides that remain in the ore to sulphates, and it is then washed in water, whereby sulphates of Fe, Cu, &c., dissolve and the tin oxide sinks to the bottom of the vessels. The tin oxide is then separated into lighter and heavier parts by agitation with water; the heavier parts are mixed with charcoal or anthracite, some lime or fluorspar is added as a flux, and the mixture is smelted in a reverberatory furnace. The product of the smelting is purified by melting, when the tin runs off, leaving the less fusible foreign metals behind; this purified tin is again melted, the molten mass is stirred with billets of green wood for some hours, and is then allowed to partially solidify by cooling, when the metal separates into different strata, which are ladled into moulds: the upper stratum is the purest and the undermost is the least pure. Sometimes the smelting is conducted in a blast furnace. For details *v.* TIN in DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 834.

Commercial tin generally contains small quantities of As, Cu, Fe, and Pb, and occasionally traces of Sb, Bi, Mn, Mo, W, and Zn. To prepare pure tin, the purest commercial metal is granulated and dissolved in conc. HClAq; a little water is very slowly poured into the liquid so as to form two layers, and a plate of tin is placed in the liquid so that part of it is in the upper (less conc.) and part in the under (more conc.) layer. A slight electric current is thus produced, and crystals of pure tin are deposited on the plate (Hiller, *A.* 85, 253).

Pure tin was prepared by Bongartz a. Classen (*B.* 21, 2903) by heating the purest commercial tin (Banca tin) in dry Cl and so forming $SnCl_4$, distilling fractionally, and collecting that which passed over at 120°, adding to the $SnCl_4$ about four times its volume of water, and then crystallised Na_2S until the pp. of SnS_2 that formed was dissolved, then adding NaOHAq about equal to half the quantity of Na_2S used, allowing to stand for some days, drawing off the clear, almost perfectly colourless liquid into a Pt basin, and passing an electric current through this alkaline liquid, washing the ppd. tin with water, then with absolute alcohol, and drying at 100°. The current was arranged so that it produced c. 2 to 3 c.c. detonating gas per minute from water; c. 2 to 3 g. tin were obtained in 24 hours.

Properties.—Pure tin is a silver-white metal; the commercial metal generally has a slightly yellowish tinge. It is unchanged in pure air; but it tarnishes in the air of large towns from formation of a film of sulphide. Tin is one of the least tenacious metals; a wire 1·6 mm. diameter breaks with a weight of c. 14 kilos. Tin may be hammered into plates c. ·0254 mm. thick; the malleability varies much with temperature, at 200° the metal is so brittle that it crumbles when hammered. Tin readily crystallises; by fusing, allowing to cool partially, and pouring out the still fluid metal, fair-sized crystals are obtained. Crystals are formed by depositing tin by electrolysis. Stolba (*J.* 1873. 282) covers the outside of a Pt basin, all except a small portion, with wax, places the unwaxed surface of the basin on a plate of amalgamated zinc in a larger porcelain basin, fills the Pt basin with a dilute and not very acid solution of $SnCl_2$, and the porcelain basin with water containing c. $\frac{1}{20}$ part of HClAq; crystals of tin deposit on the bottom of the Pt basin. The forms of the crystals of tin are probably rhombic and quadratic (von Foullon, *J. M.* 1885 (11) *Ref.* 266). According to Frankenheim (*P.* 40, 456), the crystals belong to the regular system; Miller (*B. J.* 24, 133) obtained quadratic prisms by separating tin by electrolysis. If a piece of tin is brushed over with warm, dilute *aqua regia*, or with a mixture of warm dilute H_2SO_4Aq and HNO_3Aq, the surface becomes covered with a fretwork of crystals, from the facets of which light is unequally reflected, and the surface appears like watered silk. When a bar of tin is bent a crackling sound may be heard due to the crystals in the inner parts of the bar breaking against one another. When warmed, tin has a characteristic smell.

By exposure for some time to a very low temperature (c. −39°) tin crumbles to a grey powder (*v.* Fritzsche, *B.* 2, 112, 540); S.G. c. 5·8 to 6·1 (*v.* Schertel, *J. pr.* [2] 19, 322). Tin which had been kept for 300 to 400 years was found by Schertel (*l.c.*) to have become reddish-grey, and so brittle that it was crushed by pressure between the finger-nails; by immersion in boiling water the metal became more coherent and lighter in colour, and the S.G. increased to 7·3 (*cf.* Oudemanns, *P. M.* [5] 4, 470).

Tin remains lustrous in pure air at the ordinary temperature, and also in water; a greyish-white film of SnO_2 forms on the surface of tin kept molten in the air; when heated to whiteness in air the metal burns brightly to SnO_2. Tin dissolves in HClAq, forming $SnCl_2$ solution; dilute H_2SO_4Aq has only a slight action, conc. hot H_2SO_4 produces $SnSO_4$ and SO_2; dilute HNO_3Aq dissolves tin, with formation of $Sn(NO_3)_2Aq$ and NH_4NO_3Aq, conc. HNO_3 transforms the metal into SnO_2. Tin dissolves in hot conc. NaOHAq, forming Na_2SnO_3 solution and giving off H.

When haloid compounds of tin are volatilised in a stream of H and the gas is ignited, the flame shows two cones; the inner cone is blue with $SnCl_2$, green with $SnBr_2$, and yellow with SnI_2, and gives a continuous spectrum; the outer cone is carmine-red, and gives a spectrum with two characteristic lines (Salet, *C. J.* [2] 9, 1147).

Tin is metallic physically, and in most of its chemical relations. The oxide SnO_2 interacts towards several acids as a basic oxide, forming salts SnX_2 ($X = SO_4$, &c.); but with conc. KOHAq or NaOHAq this oxide reacts as an acidic oxide, forming salts M_2SnO_3. Tin is the third member of the odd-series family of Group IV. in the periodic classification of the elements; it is closely allied to Ge and Pb, and less closely to Si; it shows very marked analogies with Ti, Zr, Ce, and Th, which (with C) form the even-series family of Group IV. For details of the chemical relations of tin *v.* TIN GROUP OF ELEMENTS, this vol. p. 735.

The atom of tin is divalent in the gaseous molecule $SnCl_2$, and tetravalent in the gaseous molecule $SnCl_4$.

Supposed allotropic form of tin. The grey brittle powder formed by the action of great cold on tin, and also found in some very old specimens of the metal, is sometimes regarded as an allotropic variety of tin (*v. supra*). All the specimens of tin, however, which have been observed to undergo this change have contained small quantities of impurities; until the change has been effected with pure tin, and has been proved to occur without any change of mass, the existence of an allotropic variety of tin cannot be said to be established. According to von Foullon (*J. M.* 1885 [1] *Ref.* 266) there are three varieties of tin: (1) rhombic, S.G. 6·52 to 6·56; (2) quadratic, S.G. 7·196; (3) grey brittle tin, S.G. 5·781 to 5·809.

Atomic weight of tin. The at. w. has been determined (1) by oxidising Sn to SnO_2 by HNO_3 (Gay-Lussac, *A. Ch.* [2] 80, 163 [1812]; Berzelius, *P.* 8, 184 [1812]; Mulder, *A.* 72, 212 [1849]; Vlaanderen, *B. J.* 1858. 183 [1858]; Dumas, *A. Ch.* [3] 55, 134 [1859]; van der Plaats, *C. R.* 100, 52 [1885]; Bongartz a. Classen, *B.* 21, 2900 [1888]); (2) by ppg. Cl from $SnCl_2$ by $AgNO_3Aq$ (Dumas, *A. Ch.* [3] 55, 156 [1859]); (3) by electrolysing $SnCl_4.2NH_4Cl$ and $SnCl_4.2KCl$ (B. a. C., *l.c.* [1888]); (4) by electrolysing $SnBr_4$ (B. a. C., *l.c.*); (5) by reducing SnO_2 in H. (v. d. P., *l.c.* [1885]); (6) by determining S.H. of Sn (Bunsen, *P.* 141, 1 [1870]); (7) by determining V.D. of, and analysing, $SnCl_2$ and $SnCl_4$. The older determinations gave values from 115·9 to 117·8. The results of the determinations of B. a. C. are summarised by them (*l.c.*, p. 2909) as follows:—

Number of experiments	Method	At. weight	Diff. between min. and max. found
11	oxidation of Sn to SnO_2	118·7606	·459
16	electrolysis of $SnCl_4.2NH_4Cl$	118·8093	·228
10	electrolysis of $SnCl_4.2KCl$	118·7975	·163
10	electrolysis of $SnBr_4$	118·7309	·144

B. a. C. regard the second and third methods as the most trustworthy; in the oxidation of Sn to SnO_2 the Pt vessel was also slightly acted on, and there was the possibility of a very small loss in dissolving $SnBr_4$ in the last method. The mean of the results obtained by the electrolysis of the two double chlorides is 118·8 (O = 15·96).

Molecular weight of tin. As the V.D. of tin has not been determined the molecular weight is not known. Ramsay determined the depression of the vapour pressure of Hg caused by dissolving tin therein; assuming that equal volumes of dilute solutions contain equal numbers of molecules of the dissolved bodies, and that the mol. w. of liquid Hg is 200, the results obtained by R. gave the mol. w. of tin as 117·4 in one experiment and 149·5° in another.

Reactions and Combinations.—1. When tin is heated in *air* or *oxygen*, a film is formed on the surface, containing both SnO and SnO_2; when heated to whiteness tin burns brightly, forming SnO_2 (*v.* Emich, *M.* 14, 345).—2. Heated in *chlorine*, *bromine*, or *iodine*, the compounds SnX_2 and SnX_4 are formed, according to whether there is excess of tin or halogen. — 3. Tin combines with *sulphur*, and with *selenion*, to form SnS and SnSe, when heated with these elements.—4. Tin probably combines with *phosphorus* when heated in vapour of that element.—5. Tin forms alloys with many *metals* (*v.* TIN, ALLOYS OF, p. 720).—6. *Water* is decomposed by tin at a full red heat with formation of SnO and H.—7. *Sulphydric acid* has a slight action on tin, in moist air, forming a film of SnS.—8. *Hydrochloric acid* dissolves the metal, forming solution of $SnCl_2$ and giving off H; the reaction proceeds more rapidly with warm conc. HClAq.—9. *Pure conc. nitric acid*, S.G. c. 1·55, has no action on tin. When the acid is diluted the products of the reaction vary with the concentration and the temperature; according to Walker (*C. J.* 63, 845), both $Sn(NO_3)_2$ and $Sn(NO_3)_4$ are formed, the quantity of $Sn(NO_3)_4$ increasing as concentration increases at a fixed temperature; with very dilute acid an increase of temperature causes only a slight increase in the quantity of the stannic salt, but the effect of temperature is very marked with more conc. acid; the proportion of stannous to stannic salt formed is only slightly affected by changing the relative masses of tin and acid; when a fairly conc. solution of tin in HNO_3Aq is heated, hydrated stannic nitrates, varying in composition, are deposited (*v.* also Montemartini, *G.* 22, 384, 397, 426; abstract in *C. J.* 62, 1402; *v.* also Hay, *C. N.* 23, 298; Scott, *C. N.* 23, 322). Pure

HNO_3 diluted sufficiently to start the reaction produces chiefly $SnO_2.xH_2O$ (*v. Hydrated stannic oxide*, under TIN OXIDES AND HYDRATED OXIDES, p. 725). When tin dissolves in HNO_3Aq, NH_4NO_3 is formed; the gases evolved are NO, N_2O, and N (*v.* Ackworth a. Armstrong, *C. J.* 32, 84).—10. A *mixture of nitric and sulphuric acids*, or *nitric and hydrochloric acids*, produces NH_2OH along with NH_3 (Divers, *C. J.* 43, 443; D. a. Shimidzu, *C. J.* 47, 597; *cf.* HYDROXYLAMINE, vol. ii. p. 734). With certain proportions of HNO_3Aq and H_2SO_4Aq, Bassett (*C. N.* 53, 172) obtained $Sn(NO_3)_2$ in solution, and almost pure N_2O.—11. *Dilute sulphuric acid* reacts slowly when warmed with tin, forming $SnSO_4$ if the tin is kept in excess, and chiefly $Sn(SO_4)_2$ if the acid is in excess, and giving off H. *Conc. sulphuric acid* reacts to form $SnSO_4$, or $Sn(SO_4)_2$, according to the proportion of tin to acid, and evolves H_2S or SO_2, or both, according to the concentration of the acid and the temperature; with pure hot H_2SO_4, SO_2 is given off, and S separates (*v.* Calvert a. Johnson, *C. J.* [2] 4, 435; also Pattison Muir a. Robbs, *C. N.* 45, 69).—12. *Aqua regia* dissolves tin, forming $SnCl_4$.—13. Tin reacts with *mercuric chloride* and *bromide*, when heated with these compounds, forming $SnCl_2$, or $SnBr_2$, and Hg.—14. With *sulphurous chloride*, $SnCl_2$ is formed, with production of much heat (Wöhler, *A.* 73, 374).—15. Tin dissolves in warm conc. *caustic potash*, or *soda*, solution, forming M_2SnO_3 and giving off H.—16. Fusion with *nitre* forms K_2SnO_3.

Detection and Estimation.—H_2S ppts. dark brown SnS from slightly acidified solutions of stannous salts; the pp. is soluble in warm yellow ammonium sulphide, forming $(NH_4)_2SnS_3Aq$, from which acids ppt. yellow SnS_2. $AuCl_3Aq$ produces a purple pp., a compound of Sn, Au, and O (*v. Purple of Cassius*, under TIN OXIDES AND HYDRATED OXIDES, p. 727). H_2S ppts. yellow SnS_2 from acidified solutions of stannic salts; the ppt. dissolves in warm yellow ammonium sulphide, and acids re-ppt. SnS_2 from this solution. Tin is generally estimated as SnO_2.

Tin, alloys of. Tin forms alloys with many metals. For a general account of the properties of different classes of tin alloys, *v.* DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 837. For alloys of tin with *antimony*, *v.* Karmarsch (*D. P. J.* 123, 267); Kestner (*Kast. Archiv*, 19, 424); Johnson (*Chem. Gazette*, 1855. 160); Chaudet (*A. Ch.* [2] 3, 376); with *bismuth and lead*, and with *bismuth, cadmium and lead*, *v.* vol. i. p. 511; with *cadmium*, *v.* vol. i. p. 655; with *cadmium and gold*, *v.* Heycock a. Neville (*C. J.* 59, 936); with *copper*, *v.* vol. ii. p. 254 (also DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 838); with *copper and lead*, *v.* vol. iii. p. 125 (also French, *S. C. I.* 8, 36); with *iridium, platinum, and rhodium*, *v.* Deville a. Debray (*C. R.* 81, 889); with *iron*, *v.* vol. iii. p. 53 (also Headden, *Am. S.* [3] 44, 464); with *gold*, *v.* Laurie (*P. M.* [5] 38, 94); with *lead*, *v.* vol. iii. p. 125; with *lead and zinc*, *v.* vol. iii. p. 125 (also Wright a. Thompson, *Pr.* 45, 461; 48, 25); with *mercury*, *v. infra*; with *platinum*, *v.* vol. iv. p. 288; with *silver*, *v.* W. a. T. (*Pr.* 48, 25); with *sodium*, *v.* Bailey (*C. N.* 65, 18). Tin alloys with *zinc* in all proportions; the alloys are harder than tin, but softer than zinc; they are less malleable than tin. Many varieties of bronze are alloys of tin with *zinc and copper* (*v.* Rudberg, *P.* 18, 240). *Amalgams of tin* are readily formed by immersing tin in Hg; the action is more rapid if the Hg is warmed (*v.* Böttger, *J. pr.* 1, 305; Joule, *Chem. Gazette*, 1850. 339, also *C. J.* 16, 384; Kupffer, *A. Ch.* [2] 40, 293).

Tin, bromides of. Tin combines with Br to form two compounds, $SnBr_2$ and $SnBr_4$. The V.D. of the latter has been determined, and the formula $SnBr_4$ is molecular; from the analogy of the chlorides it is probable that the formula $SnBr_2$ is molecular also. Watts a. Bell (*C. J.* 33, 442) obtained both $SnBr_2$ and $SnBr_4$ by heating SnO_2 in Br vapour mixed with CO.

STANNOUS BROMIDE $SnBr_2$. (*Dibromide of tin.*) Obtained by Balard (*A. Ch.* [2] 32, 337); more fully examined by Rayman a. Preis (*A.* 223, 323). Prepared by heating tin in HBr gas, allowing the oily liquid so obtained to cool, dissolving the crystals that form in dilute HBrAq, and purifying the solid that separates by distilling it in a stream of N. A crystalline, slightly yellow, transparent solid; melts at 215·5° to a transparent liquid, which solidifies at 215°. S.G. 5·117 at 17°. Carnelley a. Williams (*C. J.* 35, 563) say that $SnBr_2$ boils between 617° and 634°. Partly decomposed by water, with separation of an oxybromide of tin (R. a. P., *l.c.*). By crystallising a solution of tin in warm conc. HBrAq, R. a. P. (*l.c.*) obtained the *hydrate* $SnBr_2.xH_2O$ ($x = 1$ or 2), in colourless needles. By cooling a mixture of NH_4Cl and solution of tin in warm conc. HBrAq, the compound $SnBr_2.2NH_4Cl.H_2O$ was obtained in large rhombic, porcelain-like crystals (R. a. P., *l.c.*).

STANNIC BROMIDE $SnBr_4$. (*Tetrabromide of tin.*) Mol. w. 437·8. Melts at 30° (Carnelley a. O'Shea, *C. J.* 33, 55), at 33° (Rayman a. Preis, *A.* 223, 323). Boils at c. 201° (C. a. O'S., *l.c.*), at 203·3° (R. a. P., *l.c.*). S.G. 3·349 (R. a. P., *l.c.*). V.D. at 228°–260° = 227–230 (C. a. O'S., *l.c.*). Prepared by passing vapour of Br over melted tin in a tube shaped thus , the tin being at *b* and the Br at *a*. The tin burns in the Br vapour; the product is distilled backwards and forwards from *b* to *c* until the distillate is quite colourless. On cooling the liquid solidifies to colourless crystals of $SnBr_4$ (C. a. O'S., *l.c.*). R. a. P. (*l.c.*) prepared $SnBr_4$ by heating tin with Br, and crystallising from $SnCl_4$ or $SnBr_3Cl$. $SnBr_4$ forms white crystals, which are slowly decomposed in the air; according to R. a. P. (*l.c.*) the crystals deliquesce to a clear liquid, which when placed over H_2SO_4 deposits crystals of the *hydrate* $SnBr_4.4H_2O$. $SnBr_4$ is soluble in cold water; after some hours $SnO_2.xH_2O$ is deposited; boiling hastens this change; addition of HNO_3Aq to hot $SnBr_4Aq$ ppts. all the tin as $SnO_2.xH_2O$, with evolution of a little Br (C. a. O'S., *l.c.*). R. a. P. (*l.c.*) found that $SnBr_4$ absorbs NH_3; on heating some NH_3 was given off, and a yellow sublimate of $SnBr_4.2NH_3$ was obtained. According to Nicklès (*C. R.* 51, 869), $SnBr_4$ combines with *ether* to form $SnBr_4.Et_2O$.

Stannibromhydric acid $H_2SnBr_6.xH_2O$. (*Bromostannic acid. Hydrobromostannic acid.*) This compound was obtained by Seubert (*B.* 20, 194) by adding 74·1 parts HBrAq (50 p.c. HBr) to 100 parts $SnBr_4$ (*i.e.* in the ratio $2HBr:SnBr_4$). A yellow liquid was formed which solidified after a time to a mass of yellow, needle-shaped crystals; the small quantity of mother-liquor was removed by melting and allowing to solidify partially. It is doubtful whether the acid crystallises with 7 or $9H_2O$. The acid forms amber-yellow needles, probably triclinic; it is very deliquescent; fumes in air, giving off HBr. By adding Na_2CO_3 to H_2SnBr_6Aq, and allowing to evaporate, Seubert (*l.c.*) obtained *sodium stannibromide*, $Na_2SnBr_6.6H_2O$, in yellow needles. Several other stannibromides are described by Rayman a. Preis (*A.* 223, 323); their composition is $MSnBr_6.xH_2O$, where $M = (NH_4)_2$, Ba, Ca, Fe, Mg, Mn, Ni, Na_2, Sr, and x is 6, 8, or 10.

Tin, bromochlorides of. Rayman a. Preis (*A.* 223, 323) obtained a compound to which they gave the formula $SnBr_3Cl$ by heating tin in Br that contained some Cl, and repeatedly distilling. The compound is a liquid boiling between 181° and 190°. It dissolves $SnBr_4$, which crystallises out unchanged. By adding Br to excess of $SnCl_2$ Ladenburg (*A. Supplbd.* 8, 60) obtained indications of the formation of bromochlorides, probably $SnBr_3Cl$ and $SnBrCl_3$.

Tin, chlorides of. Tin and Cl combine to form two compounds, $SnCl_2$ and $SnCl_4$. Both formulæ are molecular.

STANNOUS CHLORIDE $SnCl_2$. (*Dichloride of tin. Tin-salt.*) Mol. w. 189·54; perhaps 379·08 ($=Sn_2Cl_4$) in the liquid state (*v. infra*). Melts at 249·3° (Carnelley a. Williams, *C. J.* 35, 63). Boils between 617° and 628° (C. a. W., *l.c.*); at 606° (Biltz a. Meyer, *Z. P. C.* 2, 184). V.D. *v. infra.* H.F. $[Sn,Cl^2] = 80{,}790$; $[Sn,Cl^2,Aq] = 81{,}140$; $[Sn,Cl^2,2H^2O] = 86{,}520$ (*Th.* 3, 327).

Preparation.—1. By heating a mixture of equal parts tin filings and $HgCl_2$; Hg sublimes and leaves $SnCl_2$.—2. By heating tin in HCl gas.—3. By dissolving tin in warm, fairly conc. HClAq, evaporating to the crystallising point, drying the crystals of $SnCl_2.2H_2O$ that separate, heating them in a capacious crucible so long as gases are given off, pouring the liquid into a small crucible, pounding when cold, and distilling from a retort; the first portions of the distillate are said to be pure $SnCl_2$ (Capitaine, *J. Ph.* 25, 552).

Properties.—A semi-transparent, white solid; melts at c. 250° and boils at incipient redness (*v. supra*). Heated to bright redness, out of air, some $SnCl_4$ is given off, then $SnCl_2$. Heated in air gives $SnCl_4$ and SnO_2. $SnCl_2$ dissolves in a little water; the solution is decomposed by much dilution, with separation of a hydrated oxychloride $SnCl_2.SnO.2H_2O$. According to Michael a. Kraft (*A. Ch.* [3] 41, 471), 1,000 c.c. saturated $SnCl_2Aq$ contains, at 15°, 1,333 g. $SnCl_2$ and 494 g. water, and the S.G. is 1·827. Gerlach (*D. P. J.* 186, 131) gives the following data for a solution of the hydrate $SnCl_2.2H_2O$:—

P.c. $SnCl_2.2H_2O$	S.G. of solution	P.c. $SnCl_2.2H_2O$	S.G. of solution
5	1·0331	45	1·3850
10	1·0684	50	1·4451
15	1·1050	55	1·5106
20	1·1442	60	1·5823
25	1·1855	65	1·6598
30	1·2300	70	1·7452
35	1·2779	75	1·8399
40	1·3298		

An aqueous solution of $SnCl_2$ generally becomes turbid from ppn. of Sn_2OCl_2; digestion with tin and a little HClAq dissolves the pp.; addition of tartaric acid, or NH_4Cl, stops the solution from becoming turbid, the former by dissolving the oxychloride, the latter by forming a double salt $SnCl_2.2NH_4Cl$, which is very soluble in water.

Mallet (*C. J.* 35, 524) obtained a semi-transparent, jelly-like solid from an aqueous solution of $SnCl_2$ which had stood in a loosely closed bottle for a year or two; the solid dried to a substance like gum arabic; it reddened litmus; the composition of the substance was $SnO_2.HCl$. Mallet writes the formula as $SnO.OH.Cl$, and suggests the name *chlor-stannic acid.*

Molecular weight of stannous chloride. The V.D. of the gas obtained by heating $SnCl_2$ has been determined repeatedly. The following table presents the results:—

Calculated for $SnCl_2$	Calculated for Sn_2Cl_4		Temp., and Observers	
94·7	189·4			
	103·7	? temp.		Rieth, *B.* 3, 668 [1870].
		185·9	at 619°	V. a. C. Meyer, *B.* 12, 1195 [1879].
		189·2	,, 697°	
	104·5		,, 800°	
	104·5		,, 800°	Meyer a. Züblin, *B.* 13, 811 [1880].
96·5			,, 880°	
90·1			,, 970°	
	123·7		,, 639°	Biltz a. Meyer, *Z. P. C.* 2, 184 [1888].
	123·7		,, 675°	
	122·9		,, 699°	
	119·5		,, 760°	
	111·4		,, 790°	
	102·7		,, 1113°	

From their determinations, Biltz a. Meyer concluded that molecules of the composition Sn_2Cl_4 do not exist in the gaseous state, and that the mol. w. of the gas comes to a constant value, corresponding with the formula $SnCl_2$, only at a temperature very much above the b.p. of the liquid ($SnCl_2$ boils at 606°). In some of the earlier determinations at c. 800° partial decomposition occurred, with production of Cl. The results, taken as a whole, seem to be explained by assuming that the molecules of the liquid, near to the b.p., have the composition Sn_2Cl_4, that some of these are dissociated to $2SnCl_2$ at c. 30° above the b.p., and that this process of dissociation continues slowly, and is not completed at even 500° above the b.p.

Reactions.—1. *Heated strongly in air*, $SnCl_4$ is given off, and SnO_2 remains. Heated to its b.p. in a retort, $SnCl_2$ and $SnCl_4$ distil, and the oxychloride Sn_2OCl_2 remains (Capitaine, *J. Ph.* 25, 552).—2. When *sulphur* is added to molten $SnCl_2$ the products are $SnCl_4$ and SnS; with *selenion* the products are $SnCl_4$ and SnSe (Schneider, *P.* 127, 624).—3. Many *salts* are reduced by $SnCl_2Aq$, either to lower salts or to metals. Au, Hg, and Ag are ppd. from solutions of their salts; ferric and manganic salts are reduced to ferrous and manganous salts; $CuCl_2Aq$ to Cu_2Cl_2.—4. The *higher oxides* of Bi, Cr, Pb, Mo, W, &c., are reduced to the lower oxides of these metals.—5. *Arsenious oxide* is reduced to As by a considerable excess of $SnCl_2Aq$.—6. According to Böttger (*Polytech. Notizbl.* 35, 96), a mixture of 2 pts. $SnCl_2$ rubbed with 1 pt.

potassium chlorate **gets hot, and produces an oxychloride of tin, $KClO_4$, oxide of chlorine, and H_2O.** For reactions with *water v. supra, Properties*; also *infra, Combinations*, No. 1.

Combinations.—1. With *water* to form the hydrate $SnCl_2.2H_2O$. This compound is prepared by dissolving tin in warm conc. HClAq and evaporating to the crystallising point, in contact with tin to prevent formation of $SnCl_4$. $SnCl_2.2H_2O$, commonly known by the name of *tin-salt*, forms large white, monoclinic crystals (Marignac, *J.* 1856. 394); melts at c. 37·7°; S.G. 2·71 at 15·5° (solid), 2·588 at 37·7° (liquid) (Penny, *C. J.* 4, 239). H.F. $[Sn,Cl^2,2H^2O]$ = 86,520 (*Th.* 3, 327). When gradually heated to 100°, most of the water is removed; when rapidly heated, H_2O and HCl are given off and Sn_2OCl_2 remains, which gives off $SnCl_2$ when more strongly heated. $SnCl_2.2H_2O$ decomposes slowly on exposure to the air, forming Sn_2OCl_2 and $SnCl_4$.—2. With *ammonia*, forming $SnCl_2.NH_3$.—3. According to Engel (*C. R.* 106, 1398), a compound of $SnCl_2$ with *hydrogen chloride* is formed by passing HCl gas over $SnCl_2.2H_2O$ at 0°; the liquid thus formed solidifies at 27°, forming crystals of $SnCl_2.HCl.3H_2O$, which melt at 40°.—4. With *chlorides of the alkali and alkaline earth metals*, to form $MCl_2.SnCl_2.xH_2O$, where $M = (NH_4)_2$, K_2, Ba, or Sr (*v.* Marignac, *C. R.* 55, 650; Rammelsberg, *Krystall. Chemie*, 211; Richardson, *Am.* 14, 89). Poggiale (*C. R.* 20, 1180) described a salt $SnCl_2.4NH_4Cl.3H_2O$. Richardson (*l.c.*) obtained $SnCl_2.KCl.H_2O$ as well as $SnCl_2.2KCl.2H_2O$. These double salts are perhaps best regarded as *stannochlorides*, derived from the acid $HSnCl_3$ (*v. Combinations*, No. 3) and the hypothetical acid H_2SnCl_4.

STANNIC CHLORIDE $SnCl_4$. (*Tetrachloride of tin.*) Mol. w. 260·28. Boils at 113·9° at 760 mm. (Thorpe, *C. J.* 37, 372); at 114·1° at 760 mm. (Young, *C. J.* 59, 912). Solidifies at −33° (Besson, *C. R.* 109, 940). S.G. $\frac{0^\circ}{4^\circ}$ 2·27875; 1·97813 at b.p. (Thorpe, *l.c.*). V.D. 133·1 at 124° (Dumas, *A. Ch.* [2] 33, 385). S.H. ·1402 (10°–15°) (Regnault, *A. Ch.* [3] 9, 332). Heat of vaporisation = 30,530 (gram-units for 1 kilo.) (Andrews, *C. J.* 1, 27). H.F. $[Sn,Cl^4]$ = 127,250; $[Sn,Cl^4,Aq]$ = 157,170; $[SnCl^2,Cl^2]$ = 46,460; $[SnCl^2Aq,Cl^2]$ = 76,030 (*Th.* 3, 327). C.E. (cubical, 0°–100°) ·00130244 (Thorpe, *l.c.*). S.V. 131·07 (Thorpe, *l.c.*; for S.V. from 0° to 280° *v.* Young, *C. J.* 59, 933, 935). For vapour pressures from −10° to 319° *v.* Young (*l.c.*, p. 927). Critical temperature = 318·7°; critical pressure = 28080 mm. (Y., *l.c.*, p. 928).

Formation.—1. By heating tin in excess of Cl.—2. By heating 1 pt. tin filings intimately mixed with 4 or 5 pts. $HgCl_2$.—3. By heating a mixture of $Sn(SO_4)_2$ and NaCl.—4. By passing vapour of CCl_4 over heated SnO_2 (Watts a. Bell, *C. J.* 33, 442).—5. By adding fuming sulphuric acid to tin, and then passing in HCl gas and distilling (Heumann a. Köchlin, *B.* 15, 416).

Preparation.—Dry Cl is led over tin filings heated in a retort connected with a dry flask, which is kept cold; the distillate is distilled from tin filings, and then repeatedly redistilled in a current of dry CO_2. A solution of $SnCl_4$ is obtained by passing Cl into $SnCl_2Aq$ until no pp. is produced with $HgCl_2Aq$, or by dissolving tin in dilute HClAq containing a little HNO_3.

Properties.—A thin, mobile, colourless, fuming, very corrosive liquid. Solidifies at −33° to small white crystals (Besson, *C. R.* 109, 940). $SnCl_4$ dissolves crystalline S, also P, I, Br, CS_2, &c. (Girardin, *C. R.* 51, 1057). $SnCl_4$ does not conduct electricity, even at its b.p.; addition of absolute alcohol forms crystals, probably ($SnCl_4.5EtOH$), which conduct when dissolved; ether behaves similarly to alcohol (Coldridge, *P. M.* [5] 29, 383, 480). $SnCl_4$ withdraws moisture from the air, probably forming $SnCl_4.3H_2O$ (*v. infra, Hydrates of stannic chloride*). $SnCl_4$ dissolves in water, with production of heat $[SnCl^4,Aq]$ = 29,920 (*Th.* 3, 327), and considerable contraction of volume (*v.* also *Reactions*, No. 1). Gerlach (*D. P. J.* 178, 49) gives the following table:—

Pcntge. $SnCl_4$	S.G. $SnCl_4Aq$	Vol. of 100 pts. by wt. of solution; vol. of 100 pts. water = 100	Vol. of mixture of $SnCl_4$ and water; vol of sum of constituents = 100
0	1·000	100·00	100·00
10	1·082	92·42	97·82
20	1·174	85·18	95·76
30	1·279	78·19	93·72
40	1·404	71·12	91·42
50	1·556	64·26	88·78
60	1·743	57·37	85·81
70	1·973	50·68	82·63
100	2·234	44·76	100·00

Hydrates of stannic chloride.—Various hydrates have been isolated: (1) $SnCl_4.3H_2O$, by exposing $SnCl_4$ to air (Casselmann, *A.* 83, 272); also by adding 18 pts. water to 260 pts. $SnCl_4$, when $\frac{2}{3}$ of the $SnCl_4$ remains unchanged, and $\frac{1}{3}$ forms the hydrate, which sinks in the excess of $SnCl_4$ (Gerlach, *D. P. J.* 178, 49); also by dissolving 260 pts. $SnCl_4$ in 54 pts. water, and letting the solution cool to 60° (G., *l.c.*); (2) $SnCl_4.2H_2O$, by keeping the trihydrate *in vacuo* (Scheurer-Kestner, *C. R.* 50, 50); also by drying the pentahydrate over H_2SO_4 (Lewy, *A. Ch.* [3] 16, 303); (3) $SnCl_4.5H_2O$, by dissolving $SnCl_4$ completely in water and evaporating (G., *l.c.*; L., *l.c.*); (4) $SnCl_4.8H_2O$, by strongly cooling dilute $SnCl_4Aq$ (G., *l.c.*); (5) $SnCl_4.9H_2O$, obtained by Nöllner (*Z.* [2] 1, 445) by treating $SnCl_2Aq$ with *aqua regia*, and exposing the solution to a winter temperature. Gerlach (*l.c.*) gives a table (*v.* next page), showing the S.G. and percentage composition of solutions of the pentahydrate.

Reactions.—1. With *water*: $SnCl_4$ dissolves in water (*v. supra*) with production of much heat. Vignon (*C. R.* 108, 1049; 109, 372) found that H_2SnO_3 ppd. from freshly prepared $SnCl_4Aq$, from $SnCl_4Aq$ after keeping, and from $SnCl_4Aq$ after heating, showed markedly different heats of neutralisation by potash. He concluded that $SnCl_4Aq$ contains HClAq and H_2SnO_3Aq, and that the H_2SnO_3 in solution gradually polymerises. Dilute $SnCl_4Aq$ gradually decomposes, giving HClAq and $SnO_2.xH_2O$ (Casselmann, *A.* 83, 272). Heating in a sealed tube with a little water is said to give SnO_2.—2. With conc. ***nitric*** *acid* $SnCl_4$ forms $SnO_2.xH_2O$.—3. **Dry *hydrogen sulphide* forms white crystals of $SnCl_4.5H_2S$, which gives off H_2S and HCl when heated, and**

leaves SnS_2 (Coldridge, *P. M.* [5] 29, 383, 480).—4. $SnCl_4$ dissolves *stannous oxide*, forming $SnCl_2$ and a solution of $SnO_2.H_2O$ in excess of $SnCl_4$ (Scheurer-Kestner, *C. R.* 50, 50).

Combinations.—1. With *hydrogen chloride.* By passing dry HCl over $SnCl_4.5H_2O$, then saturating the liquid so formed with dry HCl at 28°, and cooling to 0°, Engel (*C. R.* 103, 213) obtained white crystalline leaflets of the compound $SnCl_4.2HCl.6H_2O$, melting at c. 20°, and giving off HCl when more strongly heated. The same compound was prepared by Seubert (*B.* 20, 793) by adding to $SnCl_4$ such a quantity of conc. HClAq that the ratio of water in the acid was to the $SnCl_4$ as $6H_2O:SnCl_4$ (100 pts. $SnCl_4$ require 62·15 pts. of 33 p.c. HClAq), and after a little passing in c. 8 pts. dry HCl; the whole then solidified to a crystalline mass, melting at 19·2°. This compound is best called ***stannichlorhydric acid***; it has also been called *chlorostannic acid* (Mallet gave the name *chlor-stannic acid* to SnO.OH.Cl, *v.* STANNOUS CHLORIDE, *Properties*, p. 721), and *hydrochlorostannic acid.* Chassevant (*A. Ch.* [6] 30, 5) has described a compound $SnCl_4.HCl.3H_2O$.—2. With several *metallic chlorides.* The double salts of $SnCl_4$ and alkali and alkaline earth chlorides have the composition $MSnCl_6.xH_2O$, where M = $(NH_4)_2$, K_2, Na_2, Ba, Ca, Mg, or Sr; these salts are best named *stannichlorides* (for details, *v.* Bolley, *A.* 39, 101; Lewy, *J. pr.* 37, 479; Rammelsberg, *Krystall. chemie*; Wittstein, *R. P.* 64, 7; Topsoë, *W. A. B.* 69 [2] 261; Morel, *C. C.* 1891 [1] 492; Chassevant, *A. Ch.* [6] 30, 5). Cleve (*Bl.* [2] 31, 195) obtained double salts of the form $xSnCl_4.2MCl_3.sH_2O$, where M = Ce, Di, La, or Y, x = 2 and 5, and s had large values (from 18 to 45).—3. With certain *nonmetallic chlorides*; the compound $SnCl_4.2SCl_4$ is said to be obtained by the interaction of Cl and SnS (H. Rose, *P.* 44, 320; Casselmann, *P.* 42, 517); the compound $SnCl_4.PCl_5$ was obtained by Casselmann (*l.c.*) by heating a mixture of $SnCl_4.2SCl_4$ and PCl_3 in a stream of HCl.—4. With certain *nonmetallic oxychlorides*: (1) $SnCl_4.POCl_3$, formed by the reaction of $POCl_3$ and $SnCl_4$ (Casselmann, *A.* 91, 248; 98, 213); (2) $SnCl_4.2SeOCl_2$, by combining the constituent compounds (Weber, *B. B.* 1865. 154); (3) $SnCl_4.2NOCl$, by passing the dry vapour from *aqua regia* over $SnCl_4$ (Hampe, *A.* 126, 43), also by subliming $SnCl_4.N_2O_3$ formed by the action of N_2O and NO_2 on $SnCl_4$ (Weber a. Hampe, *P.* 118, 471).—5. With *hydrogen sulphide* to form $SnCl_4.5H_2S$; decomposed by heating to SnS_2, H_2S, and HCl (Coldridge, *P. M.* [5] 29, 383).—6. With *hydrogen cyanide*, to form crystals that are decomposed in moist air (Klein, *A.* 74, 85). 7. With *ammonia*, to form $SnCl_4.2NH_3$ according to H. Rose (*P.* 24, 163), to form $SnCl_4.4NH_3$ according to Grouvelle a. Persoz (*A. Ch.* [2] 44, 322).—8. With *phosphorus trihydride*, to form $3SnCl_4.2PH_3$ (H. Rose, *P.* 24, 159); heated to 100° in CO_2 there are formed HCl and $Sn_3P_2Cl_8$, according to Mahn (*J. Z.* 5, 160).—9. With certain *nonmetallic oxides*: (1) with SO_3 to form a solid [? composition] (H. Rose, *P.* 44, 320); (2) with NO a compound is formed, according to Kuhlmann (*A.* 39, 319), but no action occurs according to Hampe (*A.* 126, 43); (3) with N_2O_3 to form $SnCl_4.N_2O_3$, produced by passing NO_2 and N_2O over $SnCl_4$ (Hampe, *l.c.*).—10. With *ethylic alcohol*, to form $SnCl_4.5EtOH$ (Coldridge, *P. M.* [5] 29, 383, 480).—11. With *amylic alcohol*, to form $SnCl_4.2C_5H_{11}(OH)$ (Bauer a. Klein, *Z.* [2] 4, 370) 12. With *ether*, to form $SnCl_4.2Et_2O$ (Coldridge, *l.c.*).—13. With various *nitriles*, forming crystallisable compounds (Lewy, *C. R.* 21, 371).

Tin, chlorobromides of, *v.* TIN BROMOCHLORIDES, p. 721.

Tin, chloro-iodide of; *v.* TIN IODOCHLORIDE, p. 724.

Tin, chlorosulphide of; *v.* TIN THIOCHLORIDE, p. 733.

Tin, ferricyanides of; *v.* vol. ii. p. 340.

Tin, ferrocyanides of; *v.* vol. ii. p. 337.

Tin, fluorides of. Only one fluoride, SnF_2, has been isolated; double salts of stannic fluoride (SnF_4) are known.

Stannous fluoride SnF_2. (*Difluoride of tin.*) Formed, in small opaque, lustrous, prisms, by dissolving $SnO.xH_2O$ in HFAq, and evaporating; heated in air it forms the oxyfluoride $SnOF_2$ ($= SnF_4.SnO_2$) (Marignac, *Ann. M.* [5] 15, 221; Fremy, *A. Ch.* [3] 47, 37). By dissolving freshly ppd. $SnO.xH_2O$ in solutions of alkali fluorides acidified by HFAq, Wagner (*B.* 19, 896) obtained *stannofluorides* of the form $xSnF_2.2MF.yH_2O$, where $x = 1$ and 3, $y = 1$ and 2, and M was NH_4, K, and Na.

Stannic fluoride. This compound has not been isolated; a solution of $SnO_2.xH_2O$ in HFAq coagulates when heated, but does not yield any definite compound; when evaporated in air HF is given off, and an oxyfluoride, $SnOF_2$, is deposited (Marignac, *l.c.*).

Stannifluorides. A series of these salts, $MSnF_6.xH_2O$, where M = one atom of a divalent metal or two atoms of a monovalent metal, has been obtained by Marignac (*Ann. M.* [5] 15, 221). The salts are isomorphous with the corresponding silicofluorides and titanifluorides; they are generally obtained by saturating the stannates with HFAq and evaporating, some are formed by double decomposition from the Pb or Ag salt. The following salts have been obtained: $MSnF_6.xH_2O$; $M = NH_4$, Ba, Cd $x = 6$, Ca $x = 2$, Cu $x = 4$, Pb $x = 3$, Li $x = 2$, Mg $x = 6$, Mn $x = 6$, Ni $x = 6$, K $x = 1$, Ag $x = 4$, Na, Sr $x = 2$, Zn $x = 6$.

Tin, haloid compounds of. Tin and the halogens combine to form two series of compounds, SnX_2 and SnX_4 (SnF_4 has not been isolated). The V.D.s of $SnCl_2$, $SnCl_4$, and $SnBr_4$ have been determined; it is probable that the simplest formula in every case is molecular. One or two compounds of the forms SnXX′ and $SnXX_3'$ are known, where X and X′ are different halogens. A few oxyhaloid compounds are known, and probably also one or two thiohaloid compounds. The compounds $SnBr_4$ and $SnCl_4$ combine with HBr and HCl respectively, forming acids H_2SnBr_6 and H_2SnCl_6, from which series of salts, stannibromides and stannichlorides, are derived; stannifluorides are also known. An acid $HSnCl_3$ has also been isolated, and a few stannochlorides—M^ISnCl_3 and $M^I_2SnCl_4$—are known, as also some stanno-iodides.

Tin, hydrosulphide of. The compound SnS_3H_2, which has probably been isolated, may be called hydrosulphide of tin (*v.* Tin, thio-acids and salts of, p. 733).

Tin, hydroxides of, *v.* Tin oxides and hydrated oxides, p. 725; also Tin, oxyacids and salts, p. 727.

Tin, hydroxyl chloride of, SnO.OH.Cl, *v.* *Chlor-stannic acid*, under Stannous chloride, *Properties*, p. 721.

Tin, iodides of. Two compounds are formed by combining tin and I; they correspond in composition with the two bromides and the two chlorides. The V.D.s of the iodides have not been determined, but the simplest formulæ are probably molecular.

Stannous iodide SnI_2. (*Di-iodide of tin.*) Formula probably molecular.

Preparation.—1. Tin and I are heated together in the ratio Sn:2I (1 pt. tin to 2·14 pts. I); the brown crystalline solid so formed (a mixture of SnI_2 and SnI_4) is mixed with tin filings and heated, when orange-red SnI_4 sublimes, and SnI_2 remains as a red crystalline solid mixed with particles of tin, which are easily separated (Henry, *T.* 1845. 363).—2. Conc. KIAq is added to warm conc. $SnCl_2Aq$; the yellow crystalline pp. is dried and melted, out of contact with air, and a red crystalline mass of SnI_2 is formed on cooling (Boullay, *A. Ch.* [2] 34, 372).—3. Tin foil is heated for some hours with fairly conc. HIAq in a sealed tube at 120°–150° (Wöhler a. Dünhaupt, *A.* 86, 374); SnI_2 separates, on cooling, in shining yellow-red prisms.

Properties and Reactions.—A red, crystalline solid. Melts at 316° (Carnelley a. Williams, *C. J.* 35, 564). Slightly soluble in cold, more soluble in hot, water, without decomposition (Boullay, *l.c.*). According to Personne (*C. R.* 54, 216), SnI_2 is decomposed by a large quantity of water, forming HIAq and several oxyiodides (*q. v.*). SnI_2 is soluble in $SnCl_2Aq$. When heated out of contact with air, SnI_2 melts without decomposition, but when heated in the air it is decomposed to an oxyiodide, which remains in the vessel, and SnI_4, which sublimes.

Combinations.—1. With *stannous chloride* to form $SnI_2.SnCl_2$ (*v. Iodochloride, infra*).—2. With *stannous oxide* to form several oxyiodides (*q. v.*).—3. With *ammonia*, probably forming $SnI_2.2NH_3$ (Rammelsberg, *P.* 48, 169).—4. With *alkali iodides* and with *iodides of the alkaline earth metals* to form *stanno-iodides*; these salts have the composition $M_2SnI_4.xH_2O$ and $MSnI_3.xH_2O$, corresponding with the stanno-chlorides (*v.* Stannous chloride, *Combinations*, p. 722); $M = NH_4$, K, Na, also $\frac{1}{2}$Ba and $\frac{1}{2}$Sr. The stanno-iodides are formed by mixing solutions of the constitutent salts, or by adding $SnCl_2Aq$ to excess of the alkaline iodide in solution; the salts must be crystallised from alcohol, as they are decomposed by water, forming stannous oxy-iodides (*v.* Boullay, *l.c.*; Personne, *l.c.*).

Stannic iodide SnI_4. (*Tetra-iodide of tin.*) Formula probably molecular. This compound is probably formed by heating tin with 4·2 pts. I, and subliming from the product (Henry, *T.* 1845. 363). Schneider (*P.* 127, 624) recommends to add 6 pts. CS_2 to 1 pt. tin filings, and then to add gradually, cooling frequently, 4 pts. I, and to allow the yellow liquid to evaporate.

SnI_4 crystallises in orange-red octahedra; melts at 146°, sublimes at 180°, and boils at 295° (Personne, *C. R.* 54, 216). S.G. 4·696 at 11° (Bödeker, *Die Beziehungen zwischen Dichten u. Zusammensetzung bei festen u. liquiden Stoffen* [Leipzig, 1860]). Solubility in CS_2 at 15° = 145 (Schneider, *l.c.*); it is also soluble in $CHCl_3$, EtOH, Et_2O, and C_6H_6. Decomposed by water to $SnO_2.xH_2O$ and HIAq. Combines with ammonia to form $SnI_4.xNH_3$, where $x = 3$, 4, and 6 (Personne, *l.c.*), also = 8 (Rammelsberg, *P.* 48, 169). SnI_4 is said not to combine with alkali iodides.

Tin, iodochloride of, SnICl ($= SnI_2.SnCl_2$). According to Henry (*T.* 1845. 363) the addition of I to conc. $SnCl_2Aq$ causes ppn. of SnI_2, and on evaporating the mother-liquor (which contains $SnCl_2$, $SnCl_4$, and SnI_2) straw-yellow crystals are deposited that have the composition $SnI_2.SnCl_2$. The crystals are decomposed by water, with separation of SnI_2.

Tin, iodosulphide of, *v.* TIN THIO-IODIDE, p. 733.

Tin, oxides and hydrated oxides of. Two oxides have been isolated, SnO and SnO_2; various compounds of these oxides with H_2O seem to exist, but their composition readily undergoes change with variation of temperature. Both oxides interact with acids to form corresponding salts, SnX_2 and SnX_4, where $X = NO_3$, $\frac{1}{2}SO_4$, $\frac{1}{3}PO_4$, &c. Some of the hydrates of SnO_2 also react as weak acids, especially $SnO_2.H_2O$ ($= H_2SnO_3$), from which is derived a series of *stannates* $MSnO_3$, $M = Na_2$, Ca, Pb, &c.; and $xSnO_2.xH_2O$ ($= xH_2SnO_3$), x probably $= 5$, from which a series of *metastannates*, $xMSnO_3$ is derived. Stannic and metastannic acids and salts derived from them are described under the heading TIN OXYACIDS AND SALTS AND DERIVATIVES THEREOF (p. 727). The oxides SnO and SnO_2 are described in this section of the article TIN, and a brief account is also given of the experiments on the hydrates of these oxides other than stannic and metastannic acids.

When tin is strongly heated in air or oxygen a film forms on the surface consisting of SnO and SnO_2; at a full red heat, or incipient white heat, tin burns to SnO_2. According to Vignon (*C. R.* 107, 734), tin ppd. by zinc from neutral $SnCl_2Aq$ or $SnCl_4Aq$ oxidises easily in air; after being exposed to the air for some days it contains from 20 to 33 p.c. SnO. Emich (*M.* 14, 345) found that the surface of tin that was kept molten in the air became covered with crystalline nodules of SnO_2.

STANNOUS OXIDE SnO. (*Protoxide of tin.*) Mol. w. not known.

Formation.—1. By heating finely-divided tin in the air; the metal becomes covered with a film of SnO (Vignon, *C. R.* 108, 96). Also by exposing tin ppd. by zinc from $SnCl_2Aq$ or $SnCl_4Aq$ to the air at ordinary temperatures (V., *C. R.* 107, 734).—2. By dehydrating $SnO.xH_2O$, ppd. from $SnCl_2Aq$ by alkali carbonates, either by heating in a stream of CO_2, or by boiling with water containing a little KOH.—3. By dissolving $SnO.xH_2O$ in cold KOHAq, and allowing the solution to stand in the air (Ditte, *A. Ch.* [5] 27, 145).—4. By heating SnC_2O_4 in a tube of hard glass without free access of air (Liebig, *A.* 95, 116).—5. By ppg. a stannous salt by KCNAq, and boiling the pp. for some days with KCNAq (Varenne, *C. R.* 89, 360).

Preparation.—$SnCl_2Aq$ is ppd. by Na_2CO_3Aq, the white pp. of $SnO.H_2O$ is thoroughly washed with cold water, and is then boiled with water containing a little KOHAq or NaOHAq (less than sufficient to dissolve the pp.), when the $SnO.xH_2O$ is gradually dehydrated, and small black, lustrous crystals of SnO are obtained (Fremy, *A. Ch.* [3] 12, 460).—2. Tin is dissolved in warm HClAq, the solution is evaporated, in contact with tin, until it solidifies to $SnCl_2$ on cooling; 7 parts, or rather more, $Na_2CO_3.10H_2O$ are then added for each part of $SnCl_2$ in the basin, and the liquid thus formed is heated with constant stirring until it becomes black, and is then allowed to cool; the brownish-black powder, SnO, thus obtained is thoroughly washed with cold water, and dried at 100° (Sandall, *J. pr.* 14, 254).—3. A solution of $SnCl_2$ is ppd. by a slight excess of KOHAq in the cold, the pp. is thoroughly washed and dissolved in cold KOHAq (c. 1 part KOH in 10 parts H_2O); the solution, which should be saturated with $SnO.xH_2O$, is allowed to stand in the air, when SnO is gradually ppd. as small, blue-black, shining crystals (Ditte, *A. Ch.* [5] 27, 145).

Properties and Reactions.—Prepared by any of the methods described above, SnO forms small, black, lustrous, regular crystals (for crystalline form *v.* Nordenskjöld, *P.* 114, 612). S.G. 6·1 (N., *l.c.*); 6·6 at 0° (Berzelius; Ditte, *A. Ch.* [5] 27, 145).

According to Fremy (*A. Ch.* [3] 12, 460), another modification of SnO is obtained by heating the black crystals (prepared by the first process given above) to 258°; the crystals are said to swell up and change into soft, olive-green laminæ, without any change in weight.

By evaporating very dilute NH_4ClAq, holding $SnO.xH_2O$ in suspension, until NH_4Cl began to crystallise, Fremy (*A. Ch.* [3] 12, 460) obtained a cinnabar-red powder, which he took to be a third form of SnO. Retl (*A.* 60, 214) obtained red, crystalline SnO by digesting $SnO.xH_2O$, at 56°, with a solution of $SnO.xH_2O$ in acetic acid; the solution containing a little free acetic acid, and having S.G. 1·06.

For the S.G. and appearance of SnO prepared in various ways *v.* also Ditte (*l.c.*).

SnO is unchanged in air at ordinary temperatures. According to Ditte (*A. Ch.* [5] 27, 145), SnO that separates from an alkaline solution is unchanged at 300°–310°; when heated to redness it is partly decomposed to Sn, and SnO_2 which combines with unchanged SnO to give $2SnO.SnO_2$. SnO is readily converted into SnO_2 by heating with oxidising agents; the change is effected by heating to 500° in NO (Sabatier a. Senderens, *C. R.* 114, 1429). SnO dissolves in acids to form stannous salts, SnX_2, $X = NO_3$, $\frac{1}{2}SO_4$, $\frac{1}{3}PO_4$, &c.; it is not acted on by NH_3Aq; boiled with fairly conc. KOHAq or NaOHAq it gives a solution of an alkali stannate (M_2SnO_3) and tin; heated in Cl forms $SnCl_4$ and SnO_2; mixed with S and strongly heated, SnS_2 and SO_2 are produced; SnO is reduced to tin by heating to redness in H or with C.

HYDRATED STANNOUS OXIDE. The white pp. formed by adding an alkali carbonate to solution of a stannous salt, washing with air-free cold water, and drying at a temperature not above 80°, is said to have the composition $2SnO.H_2O = Sn_2O(OH)_2$. According to Ditte (*A. Ch.* [5] 27, 145) the pp. formed by adding KOHAq or NaOHAq to $SnCl_2Aq$, washing thoroughly, and drying *in vacuo* at 14° is $SnO.2H_2O$ ($= SnO_2H_2.H_2O$). Stannous hydroxide is a yellowish white amorphous powder. It is dehydrated, to SnO, by heating in CO_2; also by the action of boiling water containing a little KOH, or a trace of HCl, or acetic acid—HNO_3Aq and H_2SO_4Aq form stannous salts; also by boiling with NH_4ClAq (Ditte, *l.c.*). The hydroxide is gradually oxidised by exposure to air to $SnO_2.xH_2O$. Boiled with conc. KOHAq it gives K_2SnO_3Aq and tin. Many metallic salts are reduced, to lower salts or to the metals, by the action of $SnO.xH_2O$ (for details of the interaction with CuO in presence of alkali *v.* Lenssen, *J. pr.* 89, 90).

STANNIC OXIDE SnO_2. (*Dioxide of tin.*) Mol.

is unknown; probably at least $Sn_{10}O_{20}$ (*v.* Carnelley a. Walker, *C. J.* 53, 92).

Occurrence.—Tinstone is more or less pure SnO_2; the percentage of the oxide varies from c. 85 to c. 99, the other constituents are generally SiO_2, and oxides of Al, Fe, and Mn. Tinstone crystallises in quadratic forms. Crystalline SnO_2 has been found in the fused slag from a furnace used for casting gun-metal (Abel, *C. J.* 10, 119).

Formation.—1. By exposing molten tin to the action of the air (Emich, *M.* 14, 345).—2. By heating to c. 600° $SnO_2.xH_2O$ formed by the interaction of tin and HNO_3Aq, or of alkalis and stannic salts, or of alkali stannates and dilute acids.—3. By strongly heating SnO or $SnO.xH_2O$.—4. By passing a mixture of vapour of $SnCl_4$ and steam through a red-hot tube.—5. By heating SnC_2O_4, in small quantities, in contact with the air (Vogel, *C. C.* 1855. 413).—6. By passing a little CO_2 into a dilute solution of an alkali stannate (Ditte, *A. Ch.* [6] 30, 282).

Preparation.—A. Crystalline stannic oxide.—1. Molten tin is kept in contact with the air until the surface becomes covered with crystalline nodules of SnO_2 (Emich, *M.* 14, 345). 2. A stream of CO_2 is passed through $SnCl_4$, and then through a red-hot porcelain tube through which a current of steam is passed at the same time (Daubrée, *C. R.* 29, 227).—3. Amorphous SnO_2 is strongly heated in a rapid current of dry HCl (Deville, *C. R.* 53, 161).—4. SnC_2O_4 is strongly heated, in small quantities at a time, in an open porcelain or silver dish (Vogel, *C. C.* 1855. 413).

B. Amorphous stannic oxide.—5. The hydrated stannic oxide obtained by ppg. a stannic salt by an alkali, decomposing an alkali stannate solution by dilute acid, or by treating tin with HNO_3Aq, is thoroughly washed and dried, and then heated to c. 630°, at which temperature dehydration is complete (Carnelley a. Walker, *C. J.* 53, 83).

Properties.—Crystalline stannic oxide is a hard, lustrous, white solid. It is dimorphous. Prepared by heating the amorphous oxide in HCl gas, SnO_2 crystallises in quadratic forms isomorphous with *tinstone* and *anatase* (TiO_2) (Daubrée, *C. R.* 29, 227); prepared by decomposing vapour of $SnCl_4$ by steam, it crystallises in trimetric prisms isomorphous with *brookite* (TiO_2). S.G. of crystalline SnO_2 = 6·7 to 6·85 (Playfair a. Joule, *C. J.* 1, 137; Mallet, *J.* 3, 705; Bergemann, *J.* 10, 661; Daubrée, *C. R.* 29, 227). The crystals obtained by long continued heating molten tin in air had S.G. 7·0096 at 4° (Emick, *M.* 14, 345). Crystalline SnO_2 is hard enough to scratch glass. The amorphous oxide has S.G. 6·6 to 6·9 (P. a. J., *l.c.*; Herapath, *P. M.* 64, 321; Boullay, *A. Ch.* [2] 43, 266). It is a hard, yellowish-white powder. SnO_2 has not been fused. It is not acted on by acids (but *v. Reactions*, No. 6). Fusion with KOH or NaOH forms M_2SnO_3 which dissolves in water. The product of fusion with $KHSO_4$ dissolves in water, but addition of more water ppts. all the tin as $SnO_2.xH_2O$.

Mallet (*C. J.* 35, 524) obtained a compound $SnO_2.HCl$, to which he gave the formula SnO.OH.Cl, and the name *chlor-stannic acid*, by keeping $SnCl_4$ for a year or two in a loosely closed bottle.

Reactions.—1. Fusion with *sulphur* produce SnS_2 and SO_2.—2. When strongly heated i *chlorine* $SnCl_4$ is formed.—3. SnO_2 is reduced t tin by heating to a high temperature in *hydrogen*, or with *potassium*, *sodium*, or *carbon*, or i *carbonic oxide*.—4. Fusion with *caustic potash* o *caustic soda* forms alkali stannate (M_2SnO_3), which dissolves in water.—5. Heating with *phosphorus trichloride* to 160° forms $SnCl_2$, $SnCl_4$, and P_2O_5 (Michaelis, *J. Z.* 6, 239; 7, 110).—6. According to Ditte (*C. R.* 104, 172), SnO_2 dissolves very slowly in hot *sulphuric acid* (1 acid to 8 water), and on concentrating till not more than 3 or 4 vols. water are present to 1 vol. H_2SO_4 crystals of $SnO_2.2H_2SO_4$ separate.

HYDRATED STANNIC OXIDE. Carnelley a. Walker (*C. J.* 53, 60, 68, 83) examined the dehydrating action of heat on $SnO_2.xH_2O$, obtained by decomposing Na_2SnO_3Aq by cold dilute HClAq and drying the pp. in the air for five months. The pp. lost less and less weight for each increase of c. 10° from 50° to c. 110°, at which temperature rather less water was present than corresponded with the formula $SnO_2.H_2O$, the loss of weight for each rise of 10° was then approximately constant up to c. 360°, at which temperature the composition was nearly that required by the formula $3SnO_2.H_2O$; at a little above 360° the solid changed colour from brown to pale yellow, and at the same time lost weight at a rate nearly three times as great as during the previous rise of 100°; after changing colour the solid had the composition $7SnO_2.2H_2O$; the loss of weight, per 10° increase, then decreased very much for the next 30° or 40°, and after that dehydration continued irregularly until at 630°–635° the oxide SnO_2 remained. From these results, considered with results obtained by the same method for other hydrated oxides, C. a. W. concluded that probably a large number of hydrates of SnO_2 exists, but that none of these is stable through more than a very small range of temperature. The results of J. van Bemmelen (*B.* 13, 1466) on the dehydration by heat of stannic hydrates, obtained by oxidising tin by HNO_3Aq, and by decomposing $SnCl_4Aq$ by $CaCO_3$, and on the rehydration of the products obtained by heat, by placing them in air more or less saturated with moisture, at different temperatures, show that the quantity of water of hydration varies with variations in temperature, in the molecular states of the solids, and in the moistness of the surrounding air. Not only does the quantity of water of hydration vary with variations in the molecular state of the hydrates, but the firmness or looseness wherewith the water is held also varies much as the molecular condition varies. According to J. van B. the loosely held water is given up in dry air; and when the product is placed in moist air water is taken up until a state of equilibrium is attained wherein as many molecules of water are taken up as are lost in the unit of time.

The following compositions have been given to different hydrates of SnO_2.

I. *Hydrates obtained by decomposing soluble stannates by dilute acids*: (1) $8SnO_2.7H_2O$, by drying in a stream of dry air (Fremy, *A. Ch.* [3] 12, 462); (2) $SnO_2.2H_2O$, by drying in the air at the ordinary temperature (Weber, *P.* 122, 358); (3) $SnO_2.H_2O$, by drying *in vacuo* (Fremy, *l.c.*); (4) $8SnO_2.2H_2O$, by drying at 140° (Fremy, *l.c.*); to these should probably be added (5) $7SnO_2.2H_2O$, by drying at c. 365° (Carnelley a. Walker, *l.c.*).

II. *Hydrates obtained by oxidising tin by* HNO_3Aq: (6) $5SnO_2.10H_2O$, by drying at the ordinary temperature (Fremy, *l.c.*); (7) $5SnO_2.5H_2O$, by drying at the ordinary temperature (Thomson, *Ann. Phil.* 1817. 149), by drying over H_2SO_4 (Weber, *l.c.*), by drying *in vacuo*, or at 100° (Fremy, *l.c.*); (8) $5SnO_2.4H_2O$, by drying at 130° (Fremy, *l.c.*); (9) $5SnO_2.3H_2O$, by drying at 160° (Fremy, *l.c.*); (10) $2SnO_2.H_2O$, by drying at 55° (Thomson, *l.c.*).

The hydrates obtained by decomposing stannates by dilute acids, or by ppg. stannic salts by $CaCO_3$ or $BaCO_3$, differ in properties from the hydrates obtained by oxidising tin by HNO_3Aq; the former are generally distinguished as *stannic hydrates*, and the latter as *metastannic hydrates*. The stannic hydrates, dried in air, form hard, semi-transparent lumps, like gum arabic; soluble in the stronger acids, forming stannic salts SnX_4, where $X = NO_3, \frac{1}{2}SO_4$, &c.; soluble in alkali solutions, forming stannates $M^{I}_2SnO_3$ (*v. Stannates*, under TIN OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, *infra*). Metastannic hydrates are white solids (? crystalline) that do not dissolve in HNO_3Aq, or H_2SO_4Aq (*v. infra*). These hydrates interact with HClAq, and the product is soluble in water but insoluble in conc. HClAq; according to Weber (*P.* 122, 358), the solution gives $SnCl_4.3SnO_2.5H_2O$, when evaporated over H_2SO_4; by prolonged boiling, with fresh additions of water, all the tin in the solution is ppd. as metastannic hydrate (Fremy, *A. Ch.* [3] 12, 463; 23, 393). Metastannic hydrates dissolve in KOHAq and NaOHAq, forming metastannates $M_2H_8Sn_5O_{15}$ (*v. Metastannates*, under TIN OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, p. 730).

According to Ditte (*C. R.* 104, 172), both stannic and metastannic hydrates dissolve in warm H_2SO_4Aq (1 part acid and 8 parts water), and on concentrating till not more than 3 to 4 vols. water are present to 1 vol. H_2SO_4 the solution deposits white crystals of $SnO_2.2H_2SO_4$: these crystals are very deliquescent; they are decomposed by water; if so much water is added that not more than 43 g. H_2SO_4 are present in 1,000 c.c. of the liquid, a pp. of $SnO_2.xH_2O$ is formed. By dissolving stannic or metastannic hydrate in warm H_2SeO_4Aq, and concentrating, D. (*l.c.*) obtained crystals of $SnO_2.2H_2SeO_4$.

For further details of reactions of stannic and metastannic hydrates *v.* TIN OXYACIDS, AND SALTS AND DERIVATIVES THEREOF (*infra*).

OXIDES OF TIN OTHER THAN STANNOUS AND STANNIC OXIDES. Oxides which are most simply regarded as $xSnO.ySnO_2$ seem to exist.

According to Fuchs (*J. pr.* 5, 318), a greyish-white, slimy solid, having the composition $SnO.SnO_2 (= Sn_2O_3)$, is obtained by diffusing freshly ppd. $Fe_2O_3.xH_2O$ in $SnCl_2Aq$ free from acid, and boiling

$$(2SnCl_2Aq + Fe_2O_3 = SnO.SnO_2 + 2FeCl_2Aq).$$

This oxide is said to dissolve completely in NH_3Aq, and also in HClAq.

By digesting $SnO_2.xH_2O$, ppd. by alkali from $SnCl_4Aq$, with $SnCl_2Aq$, Schiff (*A.* 120, 53) obtained an orange-yellow solid, to which he gave the composition $SnO.6SnO_2.5H_2O$; by digesting $SnO_2.xH_2O$, formed by oxidising tin with HNO_3Aq, with $SnCl_2Aq$ Schiff (*l.c.*) obtained a yellow powder, said by him to be $SnO.6SnO_2.9H_2O$, or when dried at 85° to be $SnO.6SnO_2.4H_2O$ (*v.* also Tschermak, *C. C.* 1862. 305).

PURPLE OF CASSIUS. A purple-coloured solid is obtained by adding solution of a stannous salt to dilute $AuCl_3Aq$; this solid has been examined by many chemists, who have generally assigned to it formulæ which represent it as a compound of SnO_2, sometimes of $SnO.SnO_2$, and AuO. According to the most recent investigations the composition varies according to the conditions of preparation, and all that can be said with certainty is that the purple solid is a compound of tin, gold, and oxygen (*v.* Buisson, *J. Ph.* 16, 629; Bohlen, *Ar. Ph.* 57, 277; Capaun, *J. pr.* 22, 153; Fuchs, *J. pr.* 5, 318; Wächter, *A.* 68, 116; Figuier, *Ph. C.* 1844. 724; Debray, *C. R.* 100, 1035; Müller, *J. pr.* [2] 30, 252; and, for a bibliography (to 1866), Fischer, *D. P. J.* 182, 39).

Tin oxyacids, and salts and derivatives thereof. Some of the hydrates of SnO_2 interact with alkalis to produce salts wherein tin forms part of the acidic radicle; compounds are also known the acidic radicles whereof contain tin in combination with other negative elements besides oxygen, or tin in combination with both metallic and nonmetallic elements.

The reactions of the hydrates of SnO_2 ppd. from solutions of stannates by dilute cold acids, or ppd. from stannic salts by alkalis, are distinctly different from the reactions of the hydrates of SnO_2 obtained by oxidising tin by HNO_3Aq, or by ppn. by dilute acids from solutions of another class of salts which have the same composition as stannates, except that they always contain H and O in the ratio 2H:O in addition to the constituents of stannates. It is therefore usual to distinguish the acidic hydrates of SnO_2 as *stannic* and *metastannic acids*; to the former is given the composition $H_2SnO_3 (= SnO_2.H_2O)$, and to the latter the composition $H_{10}Sn_5O_{15} (= 5SnO_2.5H_2O)$. Neither of these formulæ is to be regarded as more than an attempt to connect the differences in the chemical behaviour of two compounds having identical percentage compositions (if the H_2O in one class is omitted) with differences in the complexities of their interacting atomic aggregates; the molecular weight of neither compound is known. It is, indeed, doubtful whether a compound with the composition xH_2SnO_3 can exist apart from other hydrates of the composition $ySnO_2.zH_2O$; it is certain that the composition of the hydrates of SnO_2 varies with very small variations of temperature, by whatever methods these hydrates are prepared (*v.* p. 726, HYDRATED STANNIC OXIDE).

That the hydrates of SnO_2, obtained respectively by ppg. solution of stannates by dilute acids and by oxidising tin by HNO_3Aq, differed in their reactions, was noticed by Berzelius in 1811 (*v. Lehrbuch* [5th ed.] 2, 596). Berzelius regarded these compounds as hydrates of two different modifications of stannic oxide; he called the oxide supposed to be a constituent of the hydrates obtained by ppg. solutions of stannates ***stannic oxide***, and designated it as $aSnO_2$; the other oxide he called *metastannic oxide*, and designated it as $bSnO_2$. Gmelin called the hydrate from stannates *ordinary stannic acid*, and the other hydrate *abnormal stannic acid.*

STANNIC ACID H_2SnO_3.

Preparation.—By adding cold dilute HClAq to an aqueous solution of K_2SnO_3, prepared by fusing SnO_2 with KOH, or by heating tin with KOH and KNO_3 (*v.* POTASSIUM STANNATE, p. 730), a gelatinous pp. is obtained which, when washed and dried *in vacuo*, has the composition $SnO_2.H_2O = H_2SnO_3$ (Fremy, *A. Ch.* [3] 12, 463). The same hydrate is formed, according to F. (*l.c.*), by adding $CaCO_3$ or $BaCO_3$ to excess of $SnCl_4Aq$, washing, and drying *in vacuo.* (For details regarding the results obtained by different chemists who have examined the compositions of the stannic hydrates, *v.* HYDRATED STANNIC OXIDE, p. 726). Graham (*T.* 1861. 213) obtained colloidal stannic acid (no analyses are given) by dissolving $SnO_2.xH_2O$ ppd. from a stannic salt (? by alkali from $SnCl_4Aq$) in $SnCl_2Aq$, and dialysing until all the Cl had passed into the dialysate. Colloidal forms of stannic acid are also obtained (1) by dialysing a solution of the ppd. acid in HClAq or in an alkali; (2) by the action of CO_2, or of air, on an alkaline solution of the ppd. acid (J. van Bemmelen, *R. T. C.* 7, 87; *abstract* in *C. J.* 54, 1160 [1888]; the results of experiments on the dehydration of the colloidal acid are given).

Properties and Reactions.—A gelatinous, amorphous solid, drying (in air or *in vacuo*) to hard, semi-transparent lumps, like gum arabic. Reddens litmus paper. Vignon (*C. R.* 108, 1049) found that the heat of neutralisation, by KOHAq, of stannic acid formed by ppg. $SnCl_4Aq$ by KOHAq, decreased when the ppd. acid was kept in contact with water for some days, and decreased more rapidly when the acid was heated with water in a sealed tube for some hours. J. van Bemmelen (*J. pr.* [2] 23, 324) found that when stannic acid is shaken with solutions of HCl, or H_2SO_4, or with solutions of certain salts, such as KCl or K_2SO_4, a definite number of molecules of the acid or salt is taken up by the stannic acid so as to form a loose combination therewith; and that the number of molecules thus absorbed varies with the proportion between the quantities of stannic acid and the acid or salt in the solution used, and also with the concentration of the solution used. The loose compounds thus formed are called *absorption-compounds* by J. van B. Dissolves in the stronger acids (HNO_3, H_2SO_4, HCl, &c.). According to Ditte (*C. R.* 104, 172), when a solution of stannic acid in warm H_2SO_4Aq (1 part acid to 8 parts water) is evaporated until not more than 3 to 4 vols. water are present to 1 vol. H_2SO_4, and allowed to cool, it yields white deliquescent crystals of $SnO_2.2H_2SO_4$; and a solution of stannic acid in warm H_2SeO_4Aq yields a similar crystalline compound $SnO_2.2H_2SeO_4$. Dissolves in excess of caustic alkali solutions, forming stannates (*q. v.* p. 730) M_2SnO_3. According to J. van. B. (*l.c.*) colloidal stannic acid does not form any compound when shaken with dilute cold KOHAq, but only complex molecular aggregates, the composition of which varies considerably with temperature and concentration. Stannic acid, dried at the ordinary temperature by pressure, is gradually changed to metastannic acid by heat; the change begins at c. 55° (J. van B., *l.c.*; *v.* also *infra*, *Change of stannic to metastannic acid, and vice versâ*). For other reactions of stannic acid *v. infra*, *Distinctions between stannic and metastannic acids.*

METASTANNIC ACID $H_{10}Sn_5O_{15}$.

Preparation.—Tin, in thin pieces or granulated, is heated with HNO_3Aq, S.G. c. 1·35, until the metal is converted into a greyish-white powder, which is washed with dilute HNO_3Aq, and then with water, and dried. The solid is said to have the composition $H_{10}Sn_5O_{15}$ ($= 5SnO_2.5H_2O$) when dried *in vacuo* (Fremy, *A. Ch.* [3] 12, 463), when dried over H_2SO_4 (Weber, *P.* 122, 358), or when dried at the ordinary temperature (Thomson, *Ann. Phil.* 1817. 149). For details of the results obtained by different chemists who have examined the compositions of the metastannic hydrates *v.* HYDRATED STANNIC OXIDE (p. 726); *v.* also J. van Bemmelen, *R. T. C.* 7, 87 (*abstract* in *C. J.* 54, 1160 [1888]). It should be noted that the empirical formula assigned to metastannic acid dried *in vacuo* (Fremy), or dried over H_2SO_4 (Weber), is the same as that assigned to stannic acid dried *in vacuo* (Fremy); this formula is $SnO_2.H_2O$. The different reactions of the two compounds show that if both have the same empirical formula one must be an isomeride or a polymeride of the other. Metastannic acid is also obtained by decomposing an aqueous solution of the sodium salt (*v.* p. 730, *Metastannates*) by boiling. Graham (*T.* 1861. 213) obtained colloidal metastannic acid by adding a little HClAq to the acid obtained by the action of HNO_3Aq on tin, dissolving the solid so formed in water, and dialysing. Vignon (*C. R.* 108, 1049) found that the heat of neutralisation of metastannic acid by KOHAq decreased when the acid was dried at 110°, and decreased very considerably when the acid was heated with water, for some hours, at 250° in a sealed tube.

Properties and Reactions.—A white powder. Insol. in nitric acid. Contact with conc. HClAq for a short time produces a compound (according to J. van Bemmelen, *R. T. C.* 7, 87; *abstract* in *C. J.* 54, 1160 [1888], no definite compound is formed, but only complex molecular aggregates of metastannic acid and HCl) which dissolves in water, but is insol. in HClAq. According to Barfoed (*J. pr.* 101, 268), the compound with HCl is quite insol. in HClAq S.G. 1·1, and may be purified by washing with acid of that concentration. The solution of this substance in water gives off HCl and H_2O, with a very little $SnCl_4$, when distilled; and metastannic acid separates out (Fremy, *A. Ch.* [3] 12, 463; 23, 393; H. Rose, *A.* 68, 272). Evaporation of the aqueous solution over H_2SO_4 is said to give an oxychloride $3SnO_2.SnCl_4.5H_2O$ (Weber, *P.* 123, 358). Metastannic hydrate dissolves in conc. HClAq after prolonged boiling, forming $SnCl_4$ solution (Löwenthal, *J. pr.* 77, 321). Barfoed (*l.c.*) says that conc. HClAq gradually converts recently ppd. and moist metastannic acid into stannic acid, and that the quantity of metastannic acid thus changed increases with the quantity of conc. HClAq, the time of contact, and the temperature. J. van Bemmelen (*J. pr.* [2] 23, 324) found that metastannic acid forms *absorption compounds* with HCl, H_2SO_4, KCl, K_2SO_4, &c.

(*cf.* Stannic acid, *Properties*, p. 728). For other reactions of the solution in water of the product of the action of HClAq on metastannic acid *v. infra*, *Distinctions between stannic and metastannic acids*. According to Ditte (*C. R.* 104, 172), metastannic acid dissolves in warm H_2SO_4Aq (1 pt. acid to 8 pts. water), forming a solution which gives crystals of $SnO_2.2H_2SO_4$ when evaporated until not more than 3 to 4 vols. water are present for one vol. H_2SO_4; the crystals are decomposed by water, with ppn. of $SnO_2.xH_2O$ (?metastannic hydrate), when sufficient water is added to insure that not more than 43 g. H_2SO_4 are present in 1,000 c.c. of the liquid. A similar compound was obtained with selenic acid, viz. $SnO_2.2H_2SeO_4$ (D., *l.c.*). Allen (*C. J.* 25, 274) found that metastannic acid dissolved in boiling conc. H_2SO_4, forming $Sn(SO_4)_2$ solution; by pouring this solution into water some of the tin was ppd., after a time, as stannic acid, but on boiling the whole of the tin came down as metastannic acid. Metastannic acid is said to dissolve slowly in fairly dilute cold KOHAq or NaOHAq; addition of conc. KOHAq or NaOHAq is said to ppt. K or Na metastannate; when the solution in KOHAq or NaOHAq stands in the air metastannic acid gradually deposits. According to J. van Bemmelen (*l.c.*), colloidal metastannic acid does not form any definite compound with KOH when shaken with KOHAq of different concentrations. By fusing metastannic acid with $KHSO_4$ or $NaHSO_4$, Allen (*C. J.* 25, 274) obtained a product which dissolved partially in water; the aqueous solution gave a pp. of metastannic acid on boiling.

Distinctions between stannic and metastannic acids (*v.* Fremy, *A. Ch.* [3] 12, 462; 23, 393; H. Rose, *P.* 75, 1; 105, 561; Löwenthal, *J. pr.* 77, 321; Barfoed, *J. pr.* 101, 368; J. van Bemmelen, *R. T. C.* 7, 87; *abstract* in *C. J.* 54, 1160 [1888]).—Stannic acid is soluble in dilute HNO_3Aq, H_2SO_4Aq, or HClAq; metastannic acid is insol. in these acids. Cold conc. HClAq dissolves stannic acid, and the solution gives the reactions of $SnCl_4$; cold conc. HClAq forms a compound (?molecular aggregates) with metastannic acid, which is insol. HClAq of S.G. 1·1, or greater S.G., but dissolves in cold water.

The following reactions apply to solutions of stannic acid in HClAq on the one hand, and to solutions in water of the substance formed by the action of HClAq on metastannic acid on the other hand. Stannic acid solution, if conc., does not become turbid on boiling; long continued boiling, with additions of water, ppts. all the acid. Metastannic acid solution, even when conc., goes turbid on boiling; long-continued boiling, accompanied by dilution, ppts. all the acid. Stannic acid solution, when distilled, gives off H_2O, with a little HCl and $SnCl_4$; and a little stannic acid separates. According to Barfoed (*J. pr.* 101, 368), when a solution of stannic acid in HClAq S.G. 1·1 is distilled, the whole of the tin passes over as $SnCl_4$. Metastannic acid solution, when distilled, gives off H_2O, with some HCl and a very little $SnCl_4$, and the meta- acid separates in the retort. Addition of tartaric acid to the stannic solution, followed by gradual addition of NH_3Aq, excess of NH_3Aq being avoided, produces no pp. Treatment of the metastannic solution with tartaric acid and NH_3Aq (not in excess) ppts. the meta- acid. $SnCl_4$Aq gives no pp. with the stannic solution; $SnCl_2$Aq gives a yellowish pp. (? $SnO.6SnO_2.9H_2O$) with the metastannic solution. Addition of dilute H_2SO_4Aq to the stannic solution produces no pp., unless the stannic solution is very much diluted. Dilute H_2SO_4Aq produces a pp. even in very dilute metastannic solution; by washing this pp. with hot water, metastannic acid remains (*cf.* Ditte's experiments are described under both Stannic acid and Metastannic acid, pp. 728, 729). The stannic solution is not ppd. by conc. HClAq. The metastannic solution, if nearly neutral, is ppd. by conc. HClAq. Addition of K_4FeCy_6Aq to the stannic solution, in the ratio $K_4FeCy_6:Sn$ present, ppts. all the tin as $SnFeCy_6$. To ppt. all the tin from the metastannic solution, the K_4FeCy_6Aq must be added in c. the ratio $19K_4FeCy_6:Sn$ present; the pp. is not $SnFeCy_6$, it is said by some observers to be metastannic acid; J. van B. (*l.c.*) calls it an *absorption compound* of metastannic acid and K_4FeCy_6. The stannic solution gives no pp. with excess of fairly conc. NaOHAq. The metastannic solution is completely ppd., as sodium metastannate, by excess of fairly conc. NaOHAq.

Change of stannic to metastannic acid and vice versâ. A solution of stannic acid in HClAq gradually changes to metastannic acid; the change is the more rapid and complete the more dilute the solution (H. Rose, *l.c.*; Barfoed, *l.c.*); by boiling for some time with repeated additions of water the whole of the stannic acid may be converted into metastannic acid. A very conc. solution of stannic acid in HClAq remains unchanged (*cf.* reaction of meta- acid with conc. HClAq, *infra*). According to Löwenthal (*l.c.*), the change from stannic to metastannic acid is stopped by addition of tartaric acid, even when the solution of stannic acid in HClAq is dilute; the amount of change to the meta- acid may be determined (according to L., *l.c.*) by finding the quantity of K_4FeCy_6Aq required to completely ppt. the tin in solution. Barfoed (*l.c.*) says the best way to measure the amount of change is to add excess of fairly conc. NaOHAq, which ppts. all the meta- acid (as a sodium salt) but none of the stannic acid.

Stannic acid is converted into the meta- acid by heat (H. Rose, *l.c.*). J. van Bemmelen (*l.c.*) found that stannic acid dried by pressure at the ordinary temperature is completely soluble in conc. HClAq, but that by heating to c. 55°, or by heating with water to below 100°, some metastannic acid is formed which is insoluble in conc. HClAq.

A solution of stannic acid in excess of KOHAq gradually deposits metastannate of K on exposure to air, with formation of K_2CO_3Aq.

Metastannic acid is gradually changed to stannic acid, according to Barfoed (*l.c.*), by contact with conc. HClAq; the quantity of stannic acid produced increases with the quantity of HClAq used, the time of contact, and the temperature.

Stannic acid is said to be obtained from the meta- acid by fusing the latter with a large excess of KOH, dissolving in water, and ppg. by cold dilute HClAq (H. Rose, *l.c.*; Fremy, *l.c.*).

Oxyacids of Tin other than Stannic and Metastannic. (1) $H_2Sn_2O_7$. Spring (*Bl.* [3] 1,

180) obtained a colloidal solid, drying at 100° to a white mass with the composition $H_2Sn_2O_7$, by adding excess of $BaO_2.xH_2O$ to a solution of $SnCl_4$ in HClAq, and dialysing the turbid liquid until $BaCl_2$ ceased to pass into the dialysate. S. regarded the new compound as an acid of the hypothetical perstannic oxide SnO_3, analogous to CeO_3, TiO_3, and (?) ZnO_2. (2) $H_4Sn_2O_6$ and $H_6Sn_3O_9$. The empirical formula of both these hydrates of stannic oxide is $SnO_2.H_2O$. According to Musculus (*C. R.* 65, 961), the hydrates differ somewhat in properties both from stannic and metastannic acids; they are said to be formed by keeping stannic acid under water, and to form K salts, $KH_3Sn_2O_6$ and $KH_5Sn_3O_9$.

Stannates, $M^{I}_2SnO_3$ and $M^{II}SnO_3$. The alkali stannates are obtained by dissolving stannic acid in MOHAq ($M = NH_4$, K, or Na), and evaporating over H_2SO_4; the stannates of the alkaline earth metals may be obtained by the interactions of solutions of the alkali stannates with MO_2H_2 or MCO_3 (M = Ba, Ca, Sr).

Ammonium stannate. A salt, said to have the composition $(NH_4)_2SnO_3.SnO_2.xH_2O$, is obtained, as a yellowish jelly, by evaporating a solution of stannic acid in NH_3Aq over H_2SO_4 (Moberg, *J. pr.* 28, 230). When K_2SnO_3Aq is added to NH_4ClAq, stannic acid is ppd. according to Ditte (*C. R.* 96, 701).

Barium stannate. The *normal salt* $BaSnO_3.6H_2O$ is said to be obtained by adding $BaCl_2Aq$ to K_2SnO_3Aq; it is described as a heavy, white powder (Moberg, *l.c.*). By adding K_2SnO_3Aq to excess of $BaCl_2Aq$, Ditte (*l.c.*) obtained a *basic salt* $BaSnO_3.BaO.10H_2O$ as lustrous leaflets.

Calcium stannate. Ditte (*l.c.*) obtained the *normal salt* $CaSnO_3.5H_2O$, in white crystals, by adding K_2SnO_3Aq to excess of $CaCl_2Aq$, washing, and drying at 100°. By heating for some hours a mixture of stannic acid and $CaCl_2Aq$, with a little CaO, D. obtained $CaSnO_3$ in regular crystals.

Potassium stannate $K_2SnO_3.xH_2O$. Prepared by dissolving stannic acid in KOHAq, or by fusing SnO_2 or metastannic acid with excess of KOH for some time and dissolving in water, and evaporating over H_2SO_4; transparent, rhombic prisms; crystallising with $4H_2O$ (Fremy, *A. Ch.* [3] 23, 393), with $3H_2O$ (Moberg, *l.c.*). Marignac (*Ann. M.* [3] 15, 277) obtained the salt, in rhombohedral crystals, by gradually heating 3 pts. metastannic acid with 8 pts. KOH till the mixture boiled, allowing to cool, dissolving in water, filtering, and evaporating. Ordway (*Am. S.* [2] 40, 173) prepared the pure salt by adding an equal volume of absolute alcohol to a solution of the commercial salt (*v. infra*), repeatedly treating the syrupy layer that separated with alcohol, drying the pasty mass so obtained by pressure, dissolving in water, evaporating *in vacuo*, and washing the crystals with alcohol. K stannate dissolves easily in water; O. (*l.c.*) gives S. at 10° = 106·6, and at 20° = 110·5; solution reacts alkaline. Insoluble in alcohol. By adding a dilute acid solution sufficient to neutralise $\frac{3}{4}$ of the alkali, a white flocculent pp. of K metastannate is said to be produced (O., *l.c.*); excess of cold dilute acid ppts. stannic acid. $K_2SnO_3.xH_2O$ is dehydrated at a red heat.

Commercial stannate of potash solution is prepared (1) by fusing tinstone with K_2S, KOH or KNO_3 and dissolving in water; (2) by boiling tinstone with KOHAq; (3) by fusing tin with KNO_3 and K_2CO_3, or boiling the metal with KOHAq containing KNO_3 and KCl (*v.* Haeffely, *D. P. J.* 144, 66; Vaughan, *B.* 5, 396; and Dictionary of Applied Chemistry, vol. iii. pp. 843–4).

Sodium stannate $Na_2SnO_3.xH_2O$. Prepared similarly to the K salt. Crystallises in hexagonal plates with $3H_2O$ (M., *l.c.*; O., *l.c.*). Marignac (*l.c.*) obtained rhombohedral crystals. Jonas (*C. C.* 1865. 607) obtained rhombic crystals of $Na_2SnO_3.9H_2O$ by recrystallising the commercial salt. Haeffely (*D. P. J.* 144, 66) obtained crystals of $Na_2SnO_3.3H_2O$ by heating an aqueous solution of S.G. 1·3; on allowing to cool again the crystals dissolved, the S.G. became 1·35, and after a time crystals of $Na_2SnO_3.8H_2O$ were deposited. Scheurer-Kestner (*Bl.* [2] 8, 839) obtained crystals of the composition $Na_2SnO_3.10H_2O$ by evaporating a dilute solution of the ordinary salt, free from excess of NaOH, at a low temperature. $Na_2SnO_3.3H_2O$ is more soluble in cold than in hot water; O. (*l.c.*) gives S. at 0° = 67·4, and at 20° = 61·3. Insoluble in alcohol. According to H. (*l.c.*), an aqueous solution of the octohydrate gives a crystalline pp. of Na metastannate when heated, or when left at the ordinary temperature for some weeks. *Commercial stannate of soda solution* is prepared similarly to the solution of the potash salt (*v. supra*).

Strontium stannate. A *basic salt* $2SrSnO_3.SrO.10H_2O$ was obtained by Ditte (*C. R.* 96, 701), in lustrous octahedra, by adding K_2SnO_3Aq to excess of $SrCl_2Aq$.

Metastannates. Only alkali metastannates have been prepared. The empirical formula of these salts is $M_2O.5SnO_2.4H_2O$; as they are decomposed by removing water, the formula is generally written as $M_2H_8Sn_5O_{15}$ (*cf.* Metastannic acid, p. 728). Metastannic acid dissolves slowly in KOHAq or NaOHAq; on adding conc. MOHAq the salts are ppd. The salts are better obtained by adding conc. MOHAq to a solution in water of the substance obtained by the interaction of metastannic acid and conc. HClAq (Barfoed, *J. pr.* 101, 368). Dilute acid solutions ppt. metastannic acid from solutions of metastannates. Metastannates heated with excess of MOH give stannates. For more details regarding $M_2H_8Sn_5O_{15}$ (M = K or Na) *v.* Fremy (*A. Ch.* [3] 23, 393); Weber (*P.* 122, 358); Haeffely (*D. P. J.* 144, 66).

ARSENIO-STANNATES. A compound $Na_2O.2As_2O_5.6SnO_2.5H_2O$ was obtained by Haeffely (*D. P. J.* 140, 290) by adding excess of HNO_3Aq to a boiling solution of Na_2SnO_3 and Na_3AsO_4, and treating the gelatinous pp. with excess of NaOHAq.

OXALO-STANNATES. The compound $2KHC_2O_4.SnO_2.5H_2O$ was obtained, in lustrous leaflets, by Péchard (*C. R.* 116, 1513) by dissolving stannic acid in hot KHC_2O_4Aq and allowing to cool.

PLATINO-STANNATES. Compounds of SnO and SnO_2 with PtO_2, derived from the acids $H_2Sn_2Pt_2O_6$ and $H_2Sn_2Pt_2O_4$ (*v.* Platino-stannates, this vol. p. 285).

PLATINO-SELENO-STANNATES *v.* this vol. p. 285.

SILICO-STANNATES. Bourgeois (*Bl.* [2] 47, 97) obtained the salt $CaO.SiO_2.SnO_2$ in monoclinic, lustrous crystals, by fusing SiO_2 and SnO_2 with excess of $CaCl_2$, and extracting with water.

In connection with stannic and metastannic acids and their derivatives, *v. Chlor-stannic acid*, under STANNOUS CHLORIDE (p. 721); TIN, OXIDES AND HYDRATED OXIDES OF (p. 725); and TIN, THIO-ACIDS AND SALTS OF (p. 735).

Tin, oxybromides of. By adding pieces of tin to the mother-liquor from $BaSnBr_6$ (*v. Stannibromides*, under STANNIC BROMIDE, p. 720). Rayman a. Preis (*A.* 223, 323) obtained colourless, prismatic crystals to which they gave the formula $Sn_3OBr_6.12H_2O$; and from the mother-liquor from this compound fine, colourless needles of $Sn_3O_2Br_8.10H_2O$ separated after a time.

Tin, oxychlorides of. According to Ditte (*A. Ch.* [5] 27, 145), when $SnO.xH_2O$, obtained by ppg. a stannous salt by NH_3Aq, is boiled with water containing a trace of $SnCl_2$, a gelatinous oxychloride is obtained having the composition $Sn_2OCl_2.6H_2O$ ($=SnO.SnCl_2.6H_2O$); and when this compound is boiled with a little more dilute $SnCl_2Aq$ another oxychloride, $Sn_5O_3Cl_4.6H_2O$ ($=3SnO.2SnCl_2.6H_2O$) is formed in small, white, pearly tablets.

The oxychloride $SnOCl_2$ is obtained, according to Scheurer-Kestner (*A. Ch.* [3] 47, 1), by evaporating $SnCl_4Aq$ at 50° to 60°; also by heating 100 pts. $SnCl_2.2H_2O$, dissolved in 50 pts. water, with HNO_3Aq containing 16 pts N_2O_5.

An oxychloride is also formed by treating metastannic acid with conc. HClAq, pouring off the excess of acid, dissolving in water, and evaporating over H_2SO_4 and CaO; to this oxychloride, which is an amorphous, white solid, Weber (*P.* 122, 358) gave the formula $Sn_4O_6Cl_4.5H_2O$ ($=3SnO_2.SnCl_4.5H_2O$). Tschermak (*W. A. B.* 44, 2) obtained a crystalline oxychloride $Sn_8O_8Cl_{14}$ ($=4SnO_2.3SnCl_4.SnCl_2$) by dissolving moist metastannic acid in hot conc. $SnCl_2Aq$ containing HCl.

Mallet (*C. J.* 35, 524) obtained a semi-transparent, jelly-like solid from $SnCl_2Aq$ which had been kept in a loosely-stoppered bottle for a year or two; to this solid he gave the formula $SnO_2.HCl$ ($=SnO.OH.Cl$).

Tin, oxyfluoride of. When SnF_2 is heated in air it is said to form the oxyfluoride $SnOF_2$ ($=SnO_2.SnF_4$) (Fremy, *A. Ch.* [3] 47, 37; Marignac, *Ann. M.* [5] 15, 221).

Tin, oxyiodides of. According to Personne (*C. R.* 54, 216), various oxyiodides are formed by decomposing SnI_2 by much water; P. analysed four compounds, to which he assigned the compositions $Sn_3O_2I_2$ ($=2SnO.SnI_2$), Sn_2OI_2 ($=SnO.SnI_2$), Sn_3OI_4 ($=SnO.2SnI_2$), and Sn_4OI_6 ($=SnO.3SnI_2$).

Tin, phosphides of. By heating finely divided tin in vapour of P, Schrötter (*W. A. B.* 1849. 301) obtained a silver-white, brittle solid to which he gave the formula SnP; S.G. 6·56; easily acted on by HClAq, but not by HNO_3Aq. Other crystalline solids have been obtained by heating tin and P together, but their compositions are not determined with certainty (*v.* Pelletier, *S.* 55, 106; Berthier, *A. Ch.* [2] 33, 180; H. Rose, *P.* 24, 326; Lüpke, *C. C.* 1890 [ii.] 643). Natanson a. Vortmann (*B.* 9, 1459) obtained a phosphide of tin by heating glacial phosphoric acid with C and tin; HClAq gave off PH_3 and left SnP.

Tin, salts of. Tin forms two classes of salts by replacing the H of acids; the *stannous* salts SnX_2 and the *stannic* salts SnX_4 ($X=ClO_3$, NO_3, $\frac{1}{2}CO_3$, $\frac{1}{2}SO_4$, $\frac{1}{3}P_4O$, &c.). The chief salts of oxyacids are the following: (1) ***Stannous salts:*** *antimonate, arsenate, borate, carbonate, chlorate, chromate, iodate, nitrate, phosphates, phosphite, sulphates*, and *sulphite*. (2) ***Stannic salts:*** *antimonate, arsenate, bromate, chlorate, iodate, molybdate, nitrate, phosphates, phosphite, selenate, selenite, sulphates*, and *tungstates* (*v.* NITRATES, SULPHATES, &c.).

Tin, selenides of. Tin and Se form two compounds, SnSe and $SnSe_2$. The former can be prepared by the direct union of the elements; the latter does not seem to be obtained by this method. Both selenides dissolve in alkali solutions, and in solutions of alkali sulphides.

STANNOUS SELENIDE SnSe. (*Tin monoselenide or protoselenide.*) Mol. w. unknown. Obtained by melting together Se and tin (Berzelius; Welsmann, *A.* 116, 122). With excess of Se the disulphide $SnSe_2$ was said to be formed (Little, *A.* 112, 213), but this was probably a mistake (Schneider, *P.* 127, 624). Also formed by adding powdered Se to molten $SnCl_2$, heating till $SnCl_4$ is volatilised, and allowing to cool, when SnSe crystallises; excess of $SnCl_2$ is removed by washing with dilute HClAq (Schneider, *l.c.*). Steel-grey, lustrous prisms; probably isomorphous with SnS; S.G. 5·24 at 15° (S., *l.c.*). Also obtained, as a black powder, by passing H_2Se into $SnCl_2Aq$, washing, and drying at 100°. SnSe prepared by ppn. is soluble in alkali solution; the crystals prepared by heating Se with $SnCl_2$ are insoluble, even in boiling alkali solutions. Both crystalline and amorphous SnSe are soluble in solutions of alkali sulphides or selenides. SnSe is insoluble in HClAq; oxidised by HNO_3Aq to $SnO_2.xH_2O$, H_2SeO_3, and H_2SeO_4. Heated with I, forms SnI_4 and $SnSe_2$; or, with an excess of I, SnI_4 and Se; reacts similarly with Br. SnSe is not reduced by heating in H. Heated in air it is gradually oxidised to SnO_2 and SeO_2 (S., *l.c.*). According to Ditte (*C. R.* 96, 1790), SnSe can be sublimed in a stream of H at a red heat; D. says S.G. is 6·179 at 0°.

STANNIC SELENIDE $SnSe_2$. (*Tin diselenide.*) Mol. w. unknown. Not formed by heating together tin and Se, as excess of Se over that required to form SnSe sublimes; Little's statement that $SnSe_2$ is formed by directly combining tin and Se by heat (*A.* 112, 213) is probably wrong (Schneider, *P.* 127, 624). Prepared by rubbing 5 pts. I and 8 to 10 pts. crystallised SnI_2 (the SnI_2 is used to enable the I to be thoroughly powdered), adding 4 pts. powdered SnSe, then sufficient CS_2 to form a pasty mass (stirring constantly), and then adding more CS_2 to dissolve SnI_4, and washing with CS_2, when $SnSe_2$ remains as a dark, red-brown, indistinctly crystalline powder, which becomes darker when dried at 100° (Schneider, *l.c.*). S.G. 4·85. According to Welsmann (*A.* 116, 122), $SnSe_2$ is obtained, as a dark reddish-brown powder, by passing H_2Se into $SnCl_4Aq$; heated in H, this powder gives off Se and leaves SnSe.

$SnSe_2$ is not acted on by water, or by dilute acids; it is slowly attacked by conc. boiling HClAq; *aqua regia*, or conc. HNO_3Aq, oxidises it to SnO_2, H_2SeO_3 and H_2SeO_4; it dissolves in hot conc. H_2SO_4, and when the olive-green solution is poured into water Se separates and $Sn(SO_4)_2$ remains dissolved. $SnSe_2$ is easily soluble in caustic alkali solutions, including NH_3Aq, forming blood-red liquids. Heated with I, in the ratio $SnSe_2$:4I, SnI_4 and Se are formed; Br reacts similarly to I (Schneider, *l.c.*).

Tin, silicides of. No definite compound has been isolated. Substances which seem to be of the nature of alloys are formed by heating together tin and Si; treatment with HClAq dissolves tin from these bodies, and separates Si along with SiO_2 (*v.* Winkler, *J. pr.* 91, 193).

Tin, silicofluoride. According to Berzelius (*Lehrbuch* [5th ed.] 3, 767), the salt $SnSiF_6$ separates (? from solution of $SnO.xH_2O$ in H_2SiF_6Aq) in prismatic crystals, which are readily crystallised from water.

Tin, sulphides of. Two sulphides of tin are known, SnS and SnS_2: the former is readily obtained by heating tin and S; the latter by heating tin with an excess of S and some substance (*e.g.* NH_4Cl) which readily volatilises, and so removes heat, which would else drive off the S above that required to form SnS. Both sulphides are also formed by ppn. by H_2S from corresponding salts in solution. Both sulphides dissolve in solutions of alkali polysulphides, forming *thiostannates*, M_2SnS_3.

STANNOUS SULPHIDE SnS. (*Tin monosulphide* or *protosulphide.*) Mol. w. unknown.

Preparation.—1. Finely divided tin is heated with c. equal parts of S; the product is powdered, and repeatedly heated with S in a closed vessel. Ditte (*C. R.* 96, 1790) recommends to sublime the SnS thus prepared, by heating to redness in a porcelain tube in a stream of H.—2. H_2S is passed into a solution of a stannous salt until the liquid smells strongly of H_2S; the brownish black pp. of amorphous SnS is washed and dried, and is then added, little by little, to molten $SnCl_2$ as long as it is dissolved thereby; after cooling, $SnCl_2$ is dissolved out by dilute HClAq, and any dark-brown powder that is present is washed away from the heavier, greyish, lustrous, crystalline particles of SnS (Schneider, *P.* 95, 167).

Properties.—A dark, lead-grey, crystalline solid; S.G. 4·85° (Karsten, *S.* 65, 394), 5·27 (Boullay, *A. Ch.* [2] 43, 266). Ditte (*l.c.*) describes SnS, after sublimation in H, as crystallising in thin, lustrous squares with an angle of c. 90°; with a grey-blue, metal-like lustre; soft and friable; S.G. 5·0802 at 0°. Crystalline SnS melts at a red heat; it expands considerably on cooling (Ditte, *l.c.*). Prepared by ppn. SnS is a brownish-black, amorphous solid.

Reactions.—1. SnS, prepared by heating together tin and S, may be sublimed in *hydrogen* at a red heat (Ditte, *C. R.* 96, 1790); but continued heating in H is said to reduce it to tin, H_2S being given off.—2. Heated in *air* SnS is gradually converted into SnO_2 and SO_2.—3. Reacts with *chlorine*, even at the ordinary temperature, to form $SnCl_4$ and $SnCl_4.2SCl_4 = (SnS_2Cl_{12})$ (H. Rose, *P.* 47, 517).—4. Fusion with *potassium cyanide* produces tin and KCNS.—5. SnS dissolves gradually in boiling *hydrochloric acid*, forming $SnCl_2$ solution and giving off H_2S (for details of interaction with HClAq of different concentration, and with HCl gas, *v.* Ditte, *C. R.* 97, 42).—6. Gradually oxidised to SnO_2 by heating with *nitric acid*.—7. Dissolves in solutions of *alkali polysulphides*, forming alkali thiostannates M_2SnS_3.—8. SnS is generally said to be nearly insoluble in solutions of *alkali monosulphides* (M_2S). According to Ditte (*C. R.* 94, 1419, 1470), SnS is not acted on by K_2SAq at the ordinary temperature if the concentration of the solution does not exceed $20K_2S:100H_2O$; but a more conc. solution of K_2SAq, out of contact with air, gradually converts the SnS into a grey, spongy mass of tin; and still more conc. K_2SAq dissolves this, forming K_2SnS_3Aq and giving off H: if air is admitted the reactions are more complex.

STANNIC SULPHIDE SnS_2. (*Tin disulphide.*) Mol. w. not known.

Preparation.—1. By saturating $SnCl_4Aq$ containing a little HClAq with H_2S, warming, again saturating with H_2S, warming gently for some hours, collecting the pp., washing with dilute H_2SAq, drying, and heating to above 100° out of contact with air. Pure SnS_2 can scarcely be prepared in this way; there seems to be always some $SnO_2.xH_2O$ present in the pp. (Kühn, *A.* 84, 110; Barfoed, *J. pr.* 101, 368).—2. By passing the mixed vapours of $SnCl_4$ and H_2S through a red-hot porcelain tube, or by passing H_2S into $SnCl_4$ and heating the white crystals of $SnCl_4.5H_2S$ so obtained (Coldridge, *P. M.* [5] 29, 383).—3. A mixture of finely-divided tin and S, or of SnS and S, with some substance that gradually volatilises and so removes heat, is slowly heated to redness in a glass retort, or a loosely covered flask, imbedded in sand; the volatile substance gradually passes off, then the excess of S is volatilised and the SnS_2 remains, partly on the sides and partly on the bottom of the vessel. If tin is heated with S only, the heat produced in the reaction is so great that the SnS_2 formed is resolved into SnS and S. Various mixtures have been employed by different chemists; the following give good results: (1) equal parts sifted tin-filings, S, and NH_4Cl (Pelletier); (2) 4 parts tin-filings, 3 parts S, 2 parts NH_4Cl (Woulfe); (3) a pulverised amalgam of 12 parts tin and 6 parts Hg, with 7 parts S, and 6 parts NH_4Cl (W.); (4) 5 parts SnS and 8 parts $HgCl_2$ (W.).

References.—Pelletier (*Crell's Chem. Ann.* 1797 [1] 46); Woulffe (*ibid.* 1, 149); Bullion (*ibid.* 1793 [1] 89); Proust (*Gehlen's Journ. f. Chem. und Phys.* 1, 250).

According to Gmelin (*Handbuch* [5th ed.] 3, 75) if NH_4Cl is heated with tin and S there is formed a compound of NH_4Cl and $SnCl_2$, which then interacts with the S, forming SnS_2 (? $2Sn + 8NH_4Cl = 2(2NH_4Cl.SnCl_2) + 2H_2 + 4NH_3$;
$2(2NH_4Cl.SnCl_2) + 2S$
$= SnS_2 + 2NH_4Cl.SnCl_4 + 2NH_4Cl$).

Properties.—Prepared by sublimation, SnS_2 is a soft golden-yellow, lustrous, crystalline solid; S.G. 4·6 (Karsten, *S.* 65, 394), 4·42 (Boullay, *A. Ch.* [2] 43, 266). Crystalline SnS_2 is known as *mosaic gold* (*v.* DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 845).

Reactions and Combinations.—1. *Heated in a closed vessel* gives SnS and S, and a sublimate of SnS_2.—2. *Heated in air* SnO_2 and SO_2 are formed.—3. *Chlorine* liquefies SnS_2, on cooling yellow crystals of $SnCl_4.2SCl_4$ are formed (H. Rose, *P.* 42, 517). — 4. The compound SnS_2I_4(= $SnSI_2.SI_2$) is said to be formed by heating SnS_2 with *iodine* in a stream of CO_2 (Schneider, *J. pr.* 79, 419; *v.* also Tin, thio-iodide, *infra*). According to Schneider (*l.c.*) a boiling alcoholic solution of I does not act on SnS_2 prepared by sublimation, but with amorphous SnS_2 prepared by ppn. it gives SnS_2I_4.—5. Amorphous, but not crystalline, SnS_2 is slowly decomposed by boiling conc. *hydrochloric acid*, H_2S being given off and $SnCl_4$ solution formed.—6. The amorphous sulphide is slowly oxidised by hot *nitric acid*; *aqua regia* oxidises both amorphous and crystalline SnS_2 to SnO_2 and H_2SO_4Aq.—7. Fusion with *lead monoxide* produces a mixture of sulphides and oxides of tin and lead; with excess of PbO, SO_2 is given off and lead remains.—8. SnS_2 was said by Dumas (*S.* 66, 409) to combine with *stannic chloride*, forming $SnS_2.2SnCl_4$; the compound being produced by the interaction of $SnCl_4$ and H_2S. According to Coldridge (*P. M.* [5] 29, 383) this compound does not exist, the product of the reaction being $SnCl_4.5H_2S$.—9. SnS_2 dissolves in *alkali sulphide solutions*, forming thiostannates (*q.v.*, *infra*), M_2SnS_3. — 10. In *alkali solutions* SnS_2 dissolves, probably forming stannates and thiostannates (? $3SnS_2 + 6KOHAq = K_2SnO_3Aq + 2K_2SnS_3Aq + 3H_2O$).

Tin Sesquisulphide. Berzelius (*Lehrbuch* [5th ed.] 2, 600) gave the formula Sn_2S_3 to a greyish-yellow, lustrous solid obtained by heating a mixture of 3 parts SnS and 1 part S in a retort; the substance was almost certainly a mixture of SnS and SnS_2.

Tin, sulphochlorides of; *v.* Tin thiochlorides, *infra.*

Tin, sulpho-iodide of; *v.* Tin thio-iodide, *infra.*

Tin, sulphocyanide of; *v.* vol. ii. p. 352.

Tin, telluride of, SnTe. A grey, lustrous, metal-like, crystalline solid; S.G. 6·478 at 0°; obtained by heating together tin and Te, and slowly subliming in a stream of H (Ditte, *C. R.* 96, 1790).

Tin, thio-acids and salts of. It is doubtful whether a thio- acid of tin has been isolated with certainty; a few salts derived from the acid H_2SnS_3 have been obtained.

Thiostannic acid. (*Sulphostannic acid.*) Kühn (*A.* 84, 110) obtained an olive-brown pp. by adding HClAq or $H.C_2H_3O_2$Aq to a conc. solution of $Na_2SnS_3.Na_2S.12H_2O$ (*v. infra*); after washing, and drying at 100°, the pp. was a leaden-grey, lustrous solid having the composition H_2SnS_3. Storch (*M.* 10, 255), repeating Kühn's experiments, always obtained brown pps., which did not contain more S than required by the ratio Sn:S = 1:2·19. S. concluded that the pps. were mixtures of H_2SnS_3 and SnS_2. By adding dilute oxalic acid solution to solution of Na_2SnS_3 (prepared by saturating Na_2SnO_3Aq with H_2S) in quantity just sufficient to combine with the Na present, S. (*l.c.*) obtained a deep-yellow liquid which remained clear for hours; after removing the H_2S by a current of air S. found that the liquid contained tin and S in the ratio Sn:3S; he concluded that H_2SnS_3 was present in the liquid. The liquid was decolourised by NH_3Aq, KOHAq, Na_2CO_3Aq, $(NH_4)_2CO_3$Aq, and NH_4ClAq; strong acids gave brownish pps. containing rather more S than required by the formula SnS_2.

Thiostannates (Kühn, *l.c.*; Höring, *Hirsel's Zeit. für Pharm.* 1851. No. 8). The alkali salts are obtained by dissolving SnS_2 in alkali sulphide solutions, M_2SAq; the alkaline earth salts are formed by double decomposition from the alkali salts.

Potassium thiostannate $K_2SnS_3.10H_2O$. Obtained by dissolving SnS_2 in K_2SAq, and adding alcohol, when the salt separates as a dark brown heavy oil; all H_2O is given off at 100°.

Sodium thiostannates. The *normal salt* $Na_2SnS_3.2H_2O$ is obtained, in yellow, glassy, regular crystals, by adding tin, little by little, to molten Na_2S_5, treating the fused mass with water, and evaporating at a low temperature. A solution of SnS and S in Na_2SAq deposits colourless, monoclinic crystals of the *basic salt*, which, when dried over H_2SO_4, has the composition $Na_2SnS_3.Na_2S.12H_2O$. The stronger acids (HCl, H_2SO_4, $CHCl_2.CO_2H$) ppt. SnS_2 at once from Na_2SnS_3Aq; but weak acids (H_3PO_4, $H_2C_2O_4$, $CH_2Cl.CO_2H$, &c.) form brown-yellow solutions from which red-brown pps. separate more or less slowly (Storch, *M.* 10, 255). Kühn (*l.c.*) gives the reactions of the two Na thiostannates with solutions of several metallic salts; many of the pps. were doubtless thiostannates of the metals employed.

PLATINO-THIOSTANNATES. Schneider (*Z.* [2] 5, 629; 6, 270, 613) obtained salts to which he gave the composition $M_2Pt_3SnS_6$ (= $M_2S.3PtS.SnS_2$), where M = K or Na, by fusing SnS_2, Pt, M_2CO_3, and S, and lixiviating with water.

Tin, thiochlorides of. A compound SnS_2Cl_{12} (= $SnCl_4.2SCl_4$) is said to be formed, along with $SnCl_4$, by the interaction of Cl and SnS or SnS_2 (H. Rose, *P.* 42, 517). Dumas (*S.* 66, 409) described a compound $Sn_2S_2Cl_4$(= $SnS_2.SnCl_4$) as obtained by passing H_2S into $SnCl_4$; but according to Coldridge (*P. M.* [5] 29, 383) this compound is not formed. C. (*l.c.*) says that the passage of H_2S into $SnCl_4$ produces white crystals of $SnCl_4.5H_2S$, which are decomposed by heat, giving off HCl and H_2S, and leaving SnS_2.

Tin, thio-iodide of. By melting together crystalline SnS_2 and I, in the ratio SnS_2:4I, allowing the liquid to cool, and either heating in a stream of CO_2, or dissolving in CS_2 and crystallising, Schneider (*J. pr.* 79, 419) obtained brown, lustrous crystals of SnS_2I_4 (= $SnSI_2.SI_2$). This thio-iodide is dissolved unchanged by CS_2 or $CHCl_3$; alcohol separates S; water, or a solution of a caustic alkali, produces SnS_2, S, and HIAq (or MIAq); HClAq or HNO_3Aq decomposes it, with separation of S. The compound SnS_2I_4 is also produced by the interaction of a solution of I in CS_2 and ppd., dried SnS_2 (S., *l.c.*). M. M. P. M.

TIN ORGANIC COMPOUNDS.

Stannic methide $SnMe_4$. (78°). S.G. 1·313. V.D. 6·00 (calc. 6·15). Got by heating an alloy of tin and sodium (14 p.c.) with MeI (¾ pt.) at 100°–120° (Ladenburg, *A. Suppl.* 8, 74; *cf.* Cahours, *A.* 111, 236; 114, 372). Oil, with ethereal odour. Reduces alcoholic $AgNO_3$.

Stannic tri-methylo-iodide $SnMe_3I$. (170°). S.G. ^{0} 2·143. Formed by the action of I on $SnMe_4$. Oil. Yields crystalline $SnMe_3OH$ and the salts $(SnMe_3)_2SO_4$, $SnMe_3.O.CO.H$, and $SnMe_3.OAc$. Forms the compounds $SnMe_3OEt$ (Ladenburg, *B.* 3, 358) and $SnMe_3I2NH_3$ (Cahours, *A.* 122, 56).

Stannic di-methylo-di-iodide $SnMe_2I_2$. [30°]. (228°). S.G. ^{22} 2·872. Formed by heating tinfoil with MeI at 150° (C.). Monoclinic crystals (from ether-alcohol). Converted by ammonia into amorphous $SnMe_2O$, which is insol. water, but dissolves in acids forming the following crystalline salts: $SnMe_2Cl_2$ [90°] (189°), forming trimetric crystals; *a*:*b*:*c* = ·834:1: ·941.—$SnMe_2PtCl_6$ 7aq, forming trimetric crystals; *a*:*b*:*c* = ·888:1:·977. — $SnMe_2Br_2$. (209°). — $SnMe_2SO_4$, forming monoclinic crystals (Hjortdahl, *C. R.* 88, 584).

Stannic ethide $SnEt_4$. Mol. w. 234. (181°). S.G. ^{23} 1·187. Formed from $SnEt_2I_2$ and EtI (Buckton, *A.* 109, 218; 112, 223; Frankland, *A.* 111, 44). Formed also, together with tin and ZnEtCl, by adding fused $SnCl_2$ to cooled $ZnEt_2$ and then distilling (Frankland a. Lawrance, *C. J.* 35, 134). Prepared by heating powdered tin with EtI and the zinc-copper couple; and also by heating ZnEtI with powdered tin at 160° (Letts a. Collie, *C. J. Proc.* 2, 166). Oil. Has no action at 180° on Al, Na, or Mg. Slowly absorbs sulphur dioxide, forming crystalline $SO_2(OSnEt_3)_2$, insol. ether and an oil $SnEt_3.SO_3Et$, sol. ether. Hot conc. HClAq forms ethane and $SnEt_3Cl$. Iodine forms $SnEt_3I$ and IEt.

Stannous ethide $SnEt_2$. S.G. ^{15} 1·558. Formed by adding zinc to a warm solution of $SnEt_2Cl_2$ (Frankland). Oil. Decomposed at 150° into $SnEt_4$ and tin. Br forms $SnEt_2Br_2$.

Distannic hexa-ethide Sn_2Et_6. (265°–270°). S.G. ^{0} 1·412. V.D. 14·8 (calc. 14·7). Got by distilling $SnEt_3I$ with sodium (Ladenburg, *A. Suppl.* 8, 66; *B.* 3, 647). Pungent oil. I forms $SnEt_3I$. Conc. HClAq forms $SnEt_2Cl_2$, ethane, and hydrogen.

Stannic tri-ethylo-iodide $SnEt_3I$. (231°). S.G. ^{22} 1·833. Formed by the action of EtI on an alloy of tin and sodium (Ladenburg, *A. Suppl.* 8, 60; *B.* 3, 353, 647; *cf.* Löwig, *A.* 84, 308). Liquid. Combines with NH_3 (2 mols.). On distilling with KOHAq it yields $SnEt_3OH$ crystallising from ether in prisms [43°] (271°) converted by heat into oily $(SnEt_3)_2O$, which recombines with water forming the hydroxide. NaOEt converts the iodide into $SnEt_3OEt$ (191°) S.G. ^{0} 1·263, which is at once changed by water into the hydroxide. The hydroxide $SnEt_3OH$ is sol. water, strongly alkaline, absorbs CO_2 from the air, and is converted by acids into the salts:—$SnEt_3Cl$. [c. 0°]. (209°). S.G. ^{8} 1·428.—$(SnEt_3)_2PtCl_6$.—$SnEt_3PtCl_5$.—$SnEt_3Br$. (223°) (Cahours). — $SnEt_3Cy$. — $SnEt_3CyO$.—$SnEt_3NO_3$.—$(SnEt_3)_2SO_4$. Hexagonal prisms terminated by pyramids (Hjortdahl).—$(SnEt_3)_2S$. — $SnEt_3SH$. — $(SnEt_3)H_2PO_4$. — $SnEt_3.OAc$. — $SnEt_3OBz$. — $(SnEt_3)_2CO_3$. — $(SnEt_3)_2C_2O_4$ aq. — Formate $(SnEt_3)CHO_2$.— Butyrate $(SnEt_3)C_4H_7O_2$. — Tartrates $(SnEt_3)_2C_4H_4O_6$ aq.—$(SnEt_3)HC_4H_4O_6$ aq.

Stannic di-ethylo-di-iodide $SnEt_2I_2$. [44·5°]. (245°). Formed from tin and EtI by exposure to sunlight or by heating with EtI at 150° (Frankland, *A.* 85, 329; Löwig, *A.* 84, 308; Cahours a. Riche, *A.* 84, 333). Needles (from alcohol), sl. sol. cold water. May be sublimed. Alcoholic NH_3 forms $SnEt_2O$, which is an amorphous powder, insol. water, converted by acids into the following salts: $SnEt_2Cl_2$. [85°]. (220°), forming trimetric crystals; *a*:*b*:*c* = ·839:1: ·943. — $SnEt_2Cl.OH$: plates.—$SnEt_2Br_2$ (233°). V.D. 11·6 (calc. 11·7).—$SnEt_2(NO_3)_2$.—$SnEt_2ICy$.—$SnEt_2(SCy)_2$. — $SnEt_2S$. — $SnEt_2SO_4$. — Crystals. $SnEt_2(OAc)_2$. — $SnEt_2C_2O_4$. — Formate $SnEt_2(CHO_2)_2$.

Stannic ethylo-trimethide $SnEtMe_3$. (125°–128°). Formed from $SnMe_3I$ and $ZnEt_2$ (Cahours, *A.* 122, 59). Oil; converted by I into EtI and $SnMe_3I$.

Stannic di-ethylo-di-methide $SnEt_2Me_2$. (145°). S.G. ^{0} 1·260. V.D. 6·84 (calc. 7·14). Formed from $SnEt_2I_2$ and $ZnMe_2$ (Frankland, *A.* 111, 50; Morgunoff, *A.* 144, 157). Oil.

Stannic methylo-tri-ethide $SnMeEt_3$. (163°). V.D. 6·72 (calc. 6·65). Formed from $SnEt_3I$ and $ZnMe_2$ in the cold (C.). Heavy oil.

Stannic tetrapropylide $SnPr_4$. (224°). S.G. ^{14} 1·179. Formed from $SnPr_3I$ and $ZnPr_2$ (Cahours, *C. R.* 76, 133). Pungent oil.

Stannic tripropylo-iodide $SnPr_3I$. (261°). S.G. ^{10} 1·692. Formed from PrI and an alloy of Na and tin (Cahours a. Demarçay, *C. R.* 88, 725, 1112). Oil, converted by moist Ag_2O into crystalline $SnEt_3OH$.

Stannic di-propylo-di-iodide $SnPr_2I_2$. (272°). Formed from tin and PrI. Oil. Converted by alkalis into amorphous $SnPr_2O$, insol. water, which yields $SnPr_2Cl_2$ [81°].

Stannic tri-isopropylo-iodide $SnPr_3I$. (257°). Got in like manner.

Stannic di-isopropylo-di-iodide $SnPr_2I_2$. (267°). Yields $SnPr_2Cl_2$ [57°].

Stannic tri-isobutylo-iodide $Sn(C_4H_9)_3I$. (285°). S.G. ^{15} 1·540. Formed from CH_2PrI and a 9 p.c. alloy of Na in tin (Cahours a. Demarçay, *C. R.* 89, 68). Pungent oil, converted by KOH into $Sn(C_4H_9)_3OH$ (313°).

Stannic di-isobutylo-di-iodide $Sn(C_4H_9)_2I_2$. (290°–295°). Formed by heating tinfoil with isobutyl iodide at 125°. Liquid, converted by alkalis into amorphous $Sn(C_4H_9)_2O$, and by HCl into $Sn(C_4H_9)_2Cl_2$ [c. 6°] (261°).

Stannic tetra-isoamylide $Sn(C_5H_{11})_4$. Formed from isoamyl iodide and an alloy of Na (1 pt.) and tin (6 pts.) (Grimm, *A.* 92, 383). Liquid.

Stannic tri-isoamylo-iodide $Sn(C_5H_{11})_3I$. (304°). Accompanies the preceding compound (C. a. D.). Converted by potash into oily $Sn(C_5H_{11})_3OH$ (337°).

Stannic tetraphenylide $SnPh_4$. [226°]. (over 420°). Formed by heating bromo-benzene with a tin-sodium alloy and acetic ether (Polis, *B.* 22, 2915). Colourless prisms, insol. ligroïn, v. sl. sol. alcohol, v. sol. boiling benzene.

Stannic tri-phenylo-chloride $SnPh_3Cl$. [105°]. Formed by the action of $NaNO_2$ on a solution of $SnPh_2Cl_2$ in HOAc, the yield being 85 p.c. of that represented by the equation $3SnPh_2Cl_2 = 2SnPh_3Cl + SnCl_4$ (Aronheim, *B.* 12, 509). Converted by potash into $SnPh_3OH$ 1$\frac{1}{2}$aq [118°].

Stannic di-phenylo-dichloride $SnPh_2Cl_2$. [42°]. (335°). Prepared by boiling $HgPh_2$ with $SnCl_4$ and ligroïn (Aronheim, *B.* 10, 2228;

11, 2285; *A.* 194, 145). Triclinic prisms; $a:b:c = \cdot588:1:1\cdot067$; $\alpha = 62°\ 47'$; $\beta = 76°\ 48'$; $\gamma = 94°\ 8'$. Sol. alcohol and ligroïn, miscible with ether. Converted by means of water into $SnPh_2Cl.OH$, an amorphous insoluble powder [187°]. Potash forms $SnPh_2O$. Ether, alcohol, and sodium-amalgam form $SnPh_2(OEt)_2$ [124°].

Stannic di-phenylo-di-bromide $SnPh_2Br_2$. [c. 38°]. (230° at 42 mm.). Formed from $SnPh_4$ and Br (Polis), and from the oxide and HBr (A.).

Stannic di-phenylo-chloro-bromide $SnPh_2BrCl$ [39°]. Crystalline. Formed from $SnPh_2Cl(OH)$ and HBr.

Stannic di-phenylo-chloro-iodide $SnPh_2ClI$. [69°]. Yellow monoclinic crystals (from ether), decomposed by water.

TIN GROUP OF ELEMENTS. Group IV. in the periodic classification of the elements contains the following members:—

Even series	2	4	6	8	10	12
	C	Ti	Zr	Ce	—	Th
Odd series	3	5	7	9	11	
	Si	Ge	Sn	—	Pb	

Subdividing this group in accordance with the chemical similarities of the elements we get the following families:—

Carbon family: C and Si.
Titanium family: Ti, Zr, Ce, —, Th.
Tin family: Ge, Sn, —, Pb.

The *carbon family* is considered in the article CARBON GROUP OF ELEMENTS (vol. i. p. 682); and that article also gives a sketch of the chemical relations of all the members of the group. The elements of the *titanium family* are considered under the heading TITANIUM GROUP OF ELEMENTS (this vol., p. 749). The *tin family* is considered in the present article.

Ge occurs in small quantities, as sulphide, in a very few rare minerals. Tin and lead are found native in not very large quantities. The chief ore of tin is *tinstone*, which contains SnO_2; SnS_2 is also found in *tin pyrites*; and various *micas* contain more or less SnO_2. *Galena*, containing PbS, is the chief ore of lead; sulphate, carbonate, phosphate, &c., are also found in considerable quantities. Ge is obtained by heating its ore with Na_2CO_3 and S, dissolving in water, decomposing Na_2S by H_2SO_4Aq, ppg. Ag (Ag_2S is a constituent of the ore) by HClAq, then ppg. GeS_2 by H_2S, oxidising the GeS_2 to GeO_2 by HNO_3, and reducing the GeO_2 by heating in H or with C. Tin is obtained by calcining *tinstone*, washing, and reducing the SnO_2 by heating with C. To obtain lead, *galena* is roasted in such a quantity of air that it is partially oxidised, both PbO and $PbSO_4$ being formed; by then heating out of contact with much air the PbS, PbO, and $PbSO_4$ interact to form SO_2 and lead. Tin and lead have been known from very early times. Ge was isolated in 1885.

The table on page 736 presents some of the principal physical and chemical properties of the tin elements.

General formulæ and characters of compounds. **Oxides**:—MO, MO_2; also Pb_3O_4 and Pb_2O_3: various hydrates of most of these oxides are known. **Sulphides**:—MS, MS_2 (?PbS_2). **Haloid compounds**:—MX_2 and MX_4. **Acids**:—H_2MX_6, where M = Ge or Sn, and X = either Br, Cl, F, or I; also H_2PbI_4; H_2SnO_3 and $H_2.H_8Sn_5O_{15}$; ?H_2SnS_3. **Salts**:—MX_2 and MX_4, where M = Sn or Pb and X = NO_3, $\frac{1}{2}SO_4$, $\frac{1}{3}PO_4$, &c. **Salts containing M in the acidic radicle**:—$R^I_2MX_6$, where M = Ge, Sn, (?Pb), and X is a halogen; $R^I_2MO_3$, where M = Sn, or Pb; also $R^I_4PbO_4$; also $R^I_2.H_8Sn_5O_{15}$; also $R^I_2SnS_3$.

The *oxides* MO are basic; they react with acids to form salts MX_2, X = NO_3, $\frac{1}{2}SO_4$, $\frac{1}{3}PO_4$, &c. (no salts of GeO have yet been isolated). PbO also dissolves in molten KOH, forming K_2PbO_2. The oxides MO_2, where M = Sn or Pb, are both basic and acidic; they react with some acids to form salts MX_4; several of these salts have been isolated when M = Sn, very few when M = Pb: they also react with molten KOH or NaOH ($SnO_2.xH_2O$ also with MOHAq) to form salts K_2(orNa_2)MO_3; when M = Sn two classes of salts are known, *stannates* M_2SnO_3, and *metastannates*, probably $M_2.H_8Sn_5O_{15}$. GeO_2 dissolves in acids, also in molten KOH or K_2CO_3, but the products of these reactions have not yet been examined. Pb_3O_4 reacts with dilute strong acids to form PbO_2, and PbX_2 which dissolves; with glacial acetic acid Pb_3O_4 forms $Pb(C_2H_3O_2)_2$ and $Pb(C_2H_3O_2)_4$. Pb_2O_3 probably reacts with dilute strong acids to give PbO_2 and a salt of PbO. The hydrates of MO and MO_2 react similarly to the oxides. Some of the hydrates $SnO_2.xH_2O$ are acidic; one class of these is probably polymeric with the other. There are indications of the existence of an oxide MO_3 in the case of tin; this oxide seems to be acidic.

The *sulphides* of Ge have not been much investigated; GeS_2 dissolves in alkali sulphide solutions, and is probably acidic. GeS has been gasified and V.D. determined. The sulphides of tin are both basic and acidic; with hot conc. HClAq they give $SnCl_2$ and $SnCl_4$ respectively; both dissolve in alkali sulphide solutions to form *thiostannates* M_2SnS_3. PbS is basic; with acids it gives salts PbX_2, and H_2S; there are indications of the existence of a higher sulphide, perhaps PbS_2, which will probably form thioplumbates with the sulphides of strongly positive metals.

The *haloid compounds* MX_2 (none isolated yet when M = Ge) may be formed by the direct union of the elements, and by the other usual methods. $SnCl_2$ and $PbCl_2$ have been gasified, and the formulæ are molecular; molecules of the composition Sn_2Cl_4 probably exist, but are decomposed at c. the boiling-point of the compound. Several salts are known of the form M_2SnX_4, where X = Br, Cl, F, or I; and an acid $HSnCl_3.xH_2O$ and some salts $MSnI_3$ are also said to exist. H_2PbI_4 and salts M_2PbI_4 have been isolated; and also several salts coming under the general formula $xPbX_2.yNH_4Cl$, where X = Br or Cl. The haloid compounds MX_4 have been gasified, and V.D.s determined, when M = Ge and X = Cl or I, and when M = Sn and X = Br or Cl. $PbCl_4$ has not been isolated with certainty, but salts of the form M_2PbCl_6 are known, and also some salts $xPbCl_4.yNH_4Cl$. The acids H_2GeF_6, H_2SnBr_6, and H_2SnCl_6 have been obtained, and also salts derived from these acids; salts M_2SnF_6 and M_2PbCl_6 are also known. $GeHCl_3$ has been isolated. Many *oxyhaloid compounds* $x.MO.yMX_2$ and $xMO_2.yMX_4$ are known.

The *oxyacids* of tin, H_2SnO_3, and (probably) $H_2.H_8Sn_5O_{15}$, are to be classed with the weak

—	GERMANIUM.	TIN.	LEAD.
Atomic weights.	72·3	118·8	206·4
	One or more compounds of each element have been gasified. Specific heats have also been determined directly. There is some evidence in favour of the conclusion that the molecules of tin and lead, in solution in Hg, are monatomic.

Atom. wts. / *Spec. gravs.* (approx.).	13·2	16·3	18·1
Occurrence and preparation.	Double sulphide of Ge and Ag occurs as a rare mineral. GeO_2 also found in some specimens of *euxenite*, with oxides of Nb, Ta, and Y. Prepared by reducing GeO_2 by H or C.	Metal found in small quantities. SnO_2 occurs in tolerable quantities widely distributed. Prepared by reducing SnO_2 by C.	Small quantities of lead found. Chief ore contains PbS; widely distributed in considerable quantities. Prepared by interaction of PbS, PbO, and $PbSO_4$; also by reducing PbO by C.
Physical properties.	Greyish white, lustrous, very brittle. Crystallises in regular octahedra. Melts at c. 900°; slightly volatilised at 1,350° in N or H.	Silver-white, lustrous, malleable, but malleability varies with temperature; tenacity very small. Crystallises very easily in rhombic and quadratic forms. Melts easily (at 232°), and boils between 1,450° and 1,600°.	White, with tinge of blue; lustrous; very malleable and ductile; tenacity very small; very soft. Crystallises easily in regular octahedra. Melts easily (at 330°), but at higher temperature than tin, and boils between 1,450° and 1,600°.
Chemical properties.	Unchanged in air at ordinary temperature; oxidised to GeO_2 when heated in fine division. Combines readily with Br, Cl, and I when heated, forming GeX_4. Heated in HCl gas forms $GeHCl_3$. Dissolves in H_2SO_4Aq. No salts have yet been isolated by replacing H of oxyacids by Ge. GeO_2 dissolves in fused KOH or K_2CO_3. H_2GeF_6Aq and salts of this acid are known.	Unchanged in pure air at ordinary temperature. Heated in air gives SnO and SnO_2. Heated in Br, Cl, or I forms SnX_2 and SnX_4. Heated with S forms SnS and SnS_2; also forms SnSe and $SnSe_2$. Reacts with acids forming two series of salts, SnX_2 and SnX_4, $X = NO_3, \frac{1}{2}SO_4, \frac{1}{3}PO_4$, &c. Conc. HNO_3 produces $SnO_2.xH_2O$. SnO is basic; $SnO_2.xH_2O$ both basic and acidic, with strong acids forms salts SnX_4, and with caustic alkalis forms stannates M_2SnO_3. SnS_2 forms thio-stannates M_2SnS_3 with alkali sulphides. Stanni fluorides M_2SnF_6 are known; the acids H_2SnCl_6 and H_2SnBr_6 have been isolated. Mol. w. perhaps same as at. w. in solution in Hg. Valency of atom varies from 2 in $SnCl_2$ gas to 4 in $SnCl_4$ gas.	Tarnishes in air, film of oxide (? Pb_2O) forming on surface. Melted in air forms PbO and Pb_3O_4. Combines with halogens to form PbX_2; $PbCl_4$ also probably isolated. Combines with S and Se, forming PbS and PbSe; $PbS.xS$ also probably exists. Reacts with acids forming salts PbX_2, $X = NO_3, \frac{1}{2}SO_4, \frac{1}{3}PO_4$, &c. PbO is basic; PbO_2 feebly basic and feebly acidic; $Pb(C_2H_3O_2)_4$ has been isolated, and probably $PbCl_4$; with molten KOH, PbO_2 forms K_2PbO_3. No thioplumbates isolated. No acid H_2PbF_6, or salts thereof, isolated; but $3KF.HF.PbF_4$ probably exists. Mol. w. perhaps same as at. w. in solution in Hg. Atom is divalent in gaseous molecule $PbCl_2$, and tetravalent in gaseous molecule $PbMe_4$.

acids; the one is probably a polymeride of the other. The salts of these acids show very distinct differences: the acids themselves interact with strong acids to form salts containing tin in the positive radicles. Of *acids containing tin and halogens* the following have (probably) been isolated: $HSnCl_3$, H_2SnBr_6, and H_2SnCl_6. H_2GeF_6 is known, and H_2PbI_4 is said to exist. It is doubtful whether *thiostannic acid* H_2SnS_3 has been obtained pure, but salts of this acid have been isolated.

The salts of oxyacids containing these metals in the negative radicles are M_2SnO_3 and $M_2.H_8Sn_5O_{15}$, M_2PbO_2 and M_2PbO_3. These salts are generally easily decomposed. Oxyacids and salts of oxyacids of Ge have yet to be searched for.

Salts derived from oxyacids by replacing H by M are known when M = Sn or Pb; no Ge salts of oxyacids have yet been isolated. The tin salts belong to two classes, SnX_2 and SnX_4, where X = NO_3, $\frac{1}{2}SO_4$, $\frac{1}{3}PO_4$, &c.; both classes of salts readily undergo decomposition and show a general tendency to separate off SnO or SnO_2. Almost all the lead salts belong to the class PbX_2; they are more definite and less ready to split off oxide or decompose to basic salts than the corresponding salts of tin. $Pb(C_2H_3O_2)_4$ is the only lead salt of an oxyacid of the class PbX_4 that has been certainly isolated; it is decomposed by the least trace of moisture, giving a pp. of PbO_2.

The elements of the tin family are distinctly metallic in their physical properties, and in most of their chemical properties also; they exhibit, however, non-metallic characters in their highest salt-forming oxides, MO_2, which are acidic towards strong bases, while they also react as basic oxides towards several acids. The tin elements are less chemically metallic, on the whole, than the members of the even-series, or titanium family, of Group IV.; the two distinctly non-metallic elements of the group are the first member of the even series – carbon, and the first member of the odd series – silicon.

In considering the chemical analogies of the tin elements, the position of the members of the family in their respective series should be looked to (*v.* table in vol. iii. p. 811). Ge comes in series 5; it is preceded by Ga, Zn, and Cu, and succeeded by As, Se, and Br: tin comes in series 7; it is preceded by In, Cd, and Ag, and succeeded by Sb, Te, and I: lead comes in series 11; it is preceded by Tl, Hg, and Au, and succeeded by Bi and two unknown elements. The highest salt-forming oxides of the elements preceding and succeeding the tin elements in the series are: *series* 5, CuO, ZnO, Ga_2O_3; GeO_2; As_2O_5, SeO_3, —; *series* 5, Ag_2O, CdO, In_2O_3; SnO_2; Sb_2O_5, TeO_3, ? I_2O_7 — *series* 11, Au_2O, HgO, Tl_2O_3; PbO_2; Bi_2O_5, —, —. The preceding oxides GeO_2 are, on the whole, more basic than the oxides preceding SnO_2 or PbO_2; and the oxides succeeding GeO_2 are on the whole more acidic than the oxides succeeding SnO_2 or PbO_2. Hence we should expect the three oxides, GeO_2, SnO_2, and PbO_2 to be about equally acidic and equally basic; SnO_2, perhaps, being the most acidic of the three. Looking at the position of the tin elements in the general periodic system, we may express the relationship of these odd-series elements to the first member of the odd series of their group (Si) by the following statements: (1) Pb:Si = Tl:Al = Hg:Mg = Au:Na = Bi:P. — (2) Sn:Si = In:Al = Cd:Mg = Ag:Na = Sb:P. — (3) Ge:Si = Ga:Al = Zn:Mg = Cu:Na = As:P. On the whole, Bi is more unlike P than Tl is unlike Al, Hg is unlike Mg, or Au is unlike Na; Sb is more unlike P than In is unlike Al, Cd is unlike Mg, or Ag is unlike Na; and As is more unlike P than Ga is unlike Al, Zn is unlike Mg, or Cu is unlike Na. Hence the differences between Pb and Si, tin and Si, and Ge and Si, respectively, will be very decided. If the relations expressed in the preceding statements are worked out in detail, they show that the differences between Pb and Si will be more marked than those between tin and Si, and still more marked than those between Ge and Si; but at the same time there will not be any very great differences between these three pairs of differences. Lead, then, will on the whole be the most metallic, and Ge the least metallic, of the tin elements. But the three elements will resemble each other closely in so far as their general positive or negative character is concerned. Then, considering the resemblances and differences between consecutive pairs of elements in (1) series 3 and 5 (*i.e.* Si and Ge series), and (2) series 5 and 7 (*i.e.* Ge and tin series), and (3) series 7 and 11 (*i.e.* tin and lead series), it is evident that Ge and Si will be more alike than Ge and tin, and that Ge and tin will more closely resemble one another than tin and lead. Hence, on the whole, we may expect that Ge will form several compounds wherein the element acts distinctly as a non-metal; it is possible that GeH_4 may be isolated ($GeHCl_3$ exists). Ge will form volatilisable organic compounds; GeO_2 will probably be found to be di- or trimorphous.

Historical.—In 1791 Gregor found indications of a new element in a Cornish ironsand called *menaccanite*, from the village near which it was found (*Crell's Ann.* 1791 [1] 40, 103). The element was called *menachin* by Kirwan. In 1795 Klaproth found a compound of a new element in a mineral known as '*rother Schoerl zu Boinik in Hungarn*,' and called the element *titanium* (derived from *Titan*). In 1797 K. recognised that the chief constituent of the Hungarian mineral was the same as the characteristic constituent of *menaccanite* examined by

Gregor (K., *Beiträge zur Kentniss der Mineralkörper*). The element was isolated for the first time by Berzelius in 1824 (*P.* 4, 3).

Occurrence.—Ti never occurs native. The chief ore of Ti is more or less pure TiO_2, which occurs in different crystalline forms as *rutile* and *anatase* (tetragonal) and *brookite* (rhombic). Various minerals contain TiO_2, combined with SiO_2 and alkaline earths, *e.g.* *titanite* or *sphene* and *ferrotitanite*; compounds of titanates and niobates are found in some rare minerals, *e.g.* *polycrase*, *euxenite*, and *pyrochlore*. Varying quantities of TiO_2 occur in many *titaniferous iron ores*. The ores of Ti are found in small quantities. Some of them, especially the titaniferous iron ores, are widely distributed (for analyses of Ti ores *v.* H. Rose, *P.* 3, 163; 14, 501; 15, 276; Mosander, *P.* 19, 211; Hermann, *J.* 25, 368; Berzelius, *J. pr.* 43, 50; Rammelsberg, *P.* 1858. 507; Scheerer, *P.* 64, 489; Groth, *Tabellarische Uebersicht der Mineralien* [2nd ed.] 35; O. v. d. Pfordten, *B.* 22, 1485). Mazade (*C. R.* 34, 952) found traces of Ti compounds in the mineral spring of Negrac in France. For analyses and descriptions of *anatase*, *brookite*, and *rutile* *v.* Klein (*J. M.* 1875. 337); G. vom Rath (*ibid.* 1876. 64); Schrauf (*ibid.* 1877. 403); Koch (*ibid.* 1878. 652). Cornu (*C. R.* 86, 101, 983) obtained spectroscopic indications of the occurrence of Ti in the sun's atmosphere. The bright-reddish crystals that are often found in blast furnaces wherein titaniferous iron ore has been smelted were supposed for many years to be Ti; but Wöhler (*A.* 73, 34) showed that they contain C and N besides Ti (*v.* TITANIUM CARBONITRIDE, p. 739).

Formation.—1. By heating K_2TiF_6 with K or Na, out of contact with air (*v. Preparation*).—2. By heating $TiCl_4$ with Na in a closed iron crucible heated in a wind furnace (Nilson a. Pettersson, *W.* 4, 554; *cf.* Kern, *C. N.* 33, 57). According to Robinson a. Hutchings (*Am.* 6, 74), Ti is formed by heating $TiCl_4$ with Na to 130° in a sealed tube; but O. v. d. Pfordten (*A.* 237, 201) says that very little, if any, Ti is obtained, and that the main product is $TiCl_2$.—3. By fusing K_2TiF_6 with an equal weight of iron filings, and dissolving away the iron by HClAq (Wehrlin a. Giraud, *C. R.* 85, 288).—4. By heating $TiCl_4$ to 180° with Ag obtained by reducing a salt of Ag; Ti_2Cl_6 is also formed (Friedel a. Guérin, *A. Ch.* [5] 7, 24).

Preparation.—Finely-powdered *rutile* is mixed with double its weight of K_2CO_3, and the mixture is fused in a Pt crucible placed inside an earthenware crucible. The fused mass is powdered and dissolved in the necessary quantity of HFAq in a Pt dish; water is added to dissolve K_2TiF_6 which begins to separate, the liquid is boiled and filtered while boiling; the K_2TiF_6, which separates from the filtrate in lustrous crystalline crusts, is pressed between filter-paper, washed repeatedly with cold water, again pressed, and recrystallised several times from boiling water (Wöhler, *A.* 74, 212). The dry K_2TiF_6 is placed in a porcelain boat in a porcelain (or hard glass) tube connected with a supply of pure dry H; another boat, containing Na, is also placed in the tube; H is passed through the apparatus, and the Na is gradually vaporised and driven over the K_2TiF_6, which is heated. When the action is completed and the tube has cooled (the H stream being maintained), the solid is treated with water, which dissolves out KF, NaF, and Na (W. a. Deville, *A.* 103, 230). The Ti is finally washed with ether and dried over H_2SO_4 (*v.* Kern, *C. N.* 33, 57). Merz (*P.* 73, 48) prepared Ti by heating a mixture of six pts. K_2TiF_6 and three pts. NaCl with two pts. Na in a glass bulb placed in a sand-bath, while a stream of H was passed through the bulb, then adding zinc-powder and fusing, and dissolving out the zinc by cold dilute HClAq.

Properties.—A dark-grey or black lustrous powder; has not been obtained crystallised. Ti resembles iron reduced from Fe_2O_3 by H at a low temperature.

According to Junot (*J.* 1853. 336), Ti was obtained by him as a silver-white lustrous deposit by electrolysing a solution prepared by dissolving titanate of K in boiling H_2SO_4Aq, evaporating to a syrup, and extracting with Na_2SO_4Aq. J.'s experiments do not seem to have been repeated. Lévy (*C. R.* 110, 1368) obtained hard, steel-white, cubicle crystals, which he took to be nearly pure Ti, by passing $TiCl_4$ vapour over Si, B, or several metals heated to bright redness. L. found only 80 p.c. Ti in the crystals. Ti burns brilliantly in a flame. When heated to redness in O, it is oxidised with production of an intensely brilliant white light. Ti also burns in Cl. It decomposes water at 100°. Warm HClAq dissolves Ti easily; it is also at once dissolved by HFAq. Heated by electric sparks, Ti gives an emission-spectrum very rich in lines (*v.* Thalen, *A. Ch.* [4] 18, 239; Troost a. Hautefeuille, *C. R.* 73, 620; Cornu, *C. R.* 86, 101, 983; Liveing a. Dewar, *Pr.* 32, 402).

The atomic weight of Ti has been determined (1) by analyses of $TiCl_4$ (H. Rose, *P.* 15, 145 [1829]; Pierre, *A. Ch.* [3] 20, 257 [1847]; Thorpe, *C. J.* 47, 108 [1885]); (2) by determining the weight of TiO_2 got from a determinate weight of $TiCl_4$ (H. Rose, *l.c.*; Thorpe, *l.c.*); (3) by analyses of $TiBr_4$ (Thorpe, *l.c.*); (4) by determining the weight of TiO_2 got from a determinate weight of $TiBr_4$ (Thorpe, *l.c.*); (5) by measuring S.H. of Ti (Nilson a. Pettersson, *Z. P. C.* 1, 34); (6) by determining V.D. of $TiCl_4$ and TiI_4 (*v.* these compounds). Rose's determinations gave values for the at. w. of Ti varying from 47·92 to 48·32; Pierre's values varied from 50·2 to 50·29. The very accurate series of determinations made by Thorpe has settled the at. w. to be almost exactly 48 (48·01 if O = 16; 47·9 if O = 15·96).

The atom of Ti is tetravalent in the gaseous molecules $TiCl_4$ and TiI_4. Ti is metallic in many of its chemical properties; it decomposes water, giving off H; the oxides Ti_2O_3 and TiO_2 form corresponding salts; the chloride and iodide (and ? also bromide) can be gasified without decomposition; the sulphide TiS_2 does not show any acidic characters so far as it has been examined. The chlorides give pps. of corresponding hydrated oxides by reacting with alkalis, &c. On the other hand, Ti exhibits distinctly non-metallic or chlorous properties; hydrates of TiO_2 act as feeble acids, producing salts wherein Ti forms part of the negative radicle. The acids H_2TiF_6 and $H_2TiO_2F_4$ are known, and also salts derived therefrom. $TiCl_4$ is very easily decomposed by

water, giving HClAq and $TiO_2.xH_2O$, &c. As might be expected from the two-sided character of the reactions of Ti, most of the salts obtained by replacing the H of oxyacids by Ti are basic salts. The oxide TiO_3 has been isolated; it is probably a superoxide. Ti is closely related to Zr, Ce, and Th; these elements, with Ti, form the even-series family of Group IV. (*v.* TITANIUM GROUP OF ELEMENTS, p. 749). Ti is also closely related to Ge, Sn, and Pb, which form the odd-series elements of Group IV. (*v.* TIN GROUP OF ELEMENTS, p. 735). Ti also shows distinct relationships to C and Si, which are the first and second members of Group IV. (*v.* CARBON GROUP OF ELEMENTS, vol. i. p. 682). The similarity between Ti and Si is shown very distinctly in the titanic and silicic acids, the relations between which may be expressed by such a general equation as $nMH_4O_4 - mH_2O = M_nH_{4n-2m}O_{4n-m}$ (M = Ti or Si). Ti is the only element of Group IV. which is known to form compounds of the type $M_2TiO_2F_4 = Ti(OM)_2F_4 = TiX_6$.

Reactions and Combinations.—1. Heated in ***air*** or in *oxygen*, burns brilliantly to TiO_2.—2. Burns when heated in *chlorine*, forming Ti_4Cl.—3. TiI_4 is formed by passing vapour of *iodine* over hot Ti.—4. Combines with *nitrogen* when heated therewith (*v. Nitrides*, p. 743).—5. Ti is violently oxidised to TiO_2 by heating with *cupric oxide* or *red lead*.—6. Interacts with ***water*** at 100°, forming TiO_2 and H.—7. Dissolves in warm *hydrochloric acid*, forming Ti_2Cl_6 (Glatzel, *B.* 9, 1831; Rammelsberg, *B. B.* 1874. 490).—8. Ti dissolves easily in *hydrofluoric acid* (? forming Ti_2F_6); also in warm dilute *nitric* or *sulphuric acid*, according to Glatzel (*l.c.*), the solution in H_2SO_4Aq deposits crystals of $Ti_2(SO_4)_3$ on cooling. Conc. hot H_2SO_4 reacts with Ti, giving off SO_2 (? forming $Ti(SO_4)_2$); conc. hot HNO_3 oxidises Ti to metatitanic acid (*q. v.*, p. 747) according to Weber (*P.* 120, 287).

Detection and Estimation.—Compounds of Ti are not reduced to metal by heating on charcoal in the blowpipe flame. Ti compounds, if not containing elements which give a colour to microcosmic salt, form a colourless glass when melted in the microcosmic salt bead in the outer blowpipe flame; in the inner flame they give a glass which is colourless when hot, but becomes violet on cooling; the delicacy of the reaction is much increased by adding a little zinc to the bead (Riley, *C. J.* 12, 13). Solutions of $TiO_2.xH_2O$ in HClAq or H_2SO_4Aq give white pps. of $TiO_2.xH_2O$ on boiling; addition of a piece of tin to a solution of $TiO_2.xH_2O$ in HClAq causes evolution of H and produces a violet-blue solution which becomes rose-coloured on dilution with water (von Kobell, *P.* 62, 599). A solution of TiO_2xH_2O in HClAq gives a violet-red liquid (Ti_2Cl_6 solution) by digestion for some time with Cu (Fuchs, *A.* 56, 319). Ti is estimated as TiO_2, ppd. from solutions by a slight excess of NH_3Aq. Insoluble compounds of Ti are generally fused with $KHSO_4$, the fused mass is dissolved in water, and $TiO_2.xH_2O$ is ppd. by long continued boiling.

Titanium, alloys of. The alloys of Ti have not been much examined. Wöhler a. Michel (*A.* 113, 248; 115, 102) obtained an alloy with ***aluminium*** approaching in composition to $TiAl_3$ by heating a mixture of TiO_2, KCl, NaCl, and *cryolite*, and treating with HClAq. By heating a mixture of Ti and Al with KCl or NaCl in an earthenware crucible in a stream of H, Lévy (*C. R.* 106, 66) obtained brittle steel-grey crystals which he took to be an *isomorphous mixture* of $TiAl_4$ and $TiAl_4$. Ti alloys with *iron*; it is often present in pig-iron, but rarely in bar-iron or steel (*v.* Riley, *C. J.* 16, 387).

Titanium, bromides of. Only one bromide has been isolated, $TiBr_4$.

TITANIC BROMIDE $TiBr_4$. (*Titanium tetrabromide.*) Mol. w. has not been determined, but the formula is almost certainly molecular from analogy of $TiCl_4$ and TiI_4.

Prepared by passing Br vapour over a mixture of TiO_2 and charcoal heated to full redness, collecting the liquid that distils over and solidifies in the receiver, and redistilling it from Hg (to remove free Br) (Duppa, *Pr.* 8, 42). Also prepared by passing HBr gas over $TiCl_4$ kept a few degrees below its boiling-point in a distilling flask connected with an upright condenser; the whole of the Cl of the $TiCl_4$ is expelled (Thorpe, *C. J.* 47, 126). Thorpe used 350 g. $TiCl_4$, and continued the passage of HBr for three days. The HBr is conveniently obtained by the interaction of Br and amorphous P in a little water; it is freed from Br by passing through a U tube containing broken glass and amorphous P, and is dried by passing through another U tube containing $CaCl_2$.

$TiBr_4$ forms dark-yellow or orange crystals, S.G. 2·6, melting at c. 40°, and boiling at c. 229° (D., *l.c.*; T., *l.c.*). It is very hygroscopic, easily decomposed by water, forming a perfectly clear solution containing HBr and $TiO_2.xH_2O$.

Titanium, bromochlorides of. By adding Br to $TiCl_2$ (*q. v.*, p. 741) Friedel a. Guérin (*A. Ch.* [5] 8, 24) obtained a colourless liquid, fuming in the air, boiling at 176°, which they said was probably $TiBr_2Cl_2$; and by the reaction of Br with Ti_2Cl_6 they obtained a liquid boiling at 154°, probably $TiBrCl_3$.

Titanium, carbonitride of, Ti_5CN_4. (*Titanium nitrocyanide*, or *cyanonitride* $Ti_{10}(CN)_2N_6$.) This compound is often found in blast furnaces wherein titaniferous ironstone has been smelted. It was supposed by Wollaston to be Ti (*G. A.* 75, 220), and was for many years generally mistaken for the metal. In 1850 Wöhler (*A.* 73, 34) proved it to contain C and N besides Ti.

The compound is found in blast furnaces as lustrous, opaque, copper-coloured, prismatic crystals. By treating these crystals with conc. HClAq, then with conc. H_2SO_4, washing, treating with HFAq, and again washing, the compound is freed from admixed Fe, &c.; small leaflets of graphite generally remain mixed with the carbonitride. Ti_5CN_4 can be prepared by heating a mixture of dry K_4FeCy_6 and TiO_2 in a closed crucible for an hour or two at c. the melting-point of Ni (1400° to 1450°), dissolving out Fe, &c., by conc. HClAq, washing, and drying. By examining the brown powder thus obtained with a magnifying power of 300 diameters copper-coloured crystals of Ti_5CN_4 can be detected (Wöhler, *A.* 73, 34). It is also obtained by heating a mixture 1 part C and $5\frac{2}{3}$ parts TiO_2, in a closed carbon crucible for some hours at 1400° to 1450°; also by passing N over a mixture of C and TiO_2 in the ratio $1:5\frac{2}{3}$ heated in a carbon boat placed in a carbon tube to the melting-point of Pt (c. 1800°) (W. a. Deville, *A.* 103, 231).

When Ti_5CN_4 is fused with KOH it gives off NH_3; heated to redness in a stream of water vapour TiO_2 is formed, and H, NH_3, and HCN are given off (W., *l.c.*); heated in Cl it gives $TiCl_4$ and $TiCl_4.2HCN$ (W., *l.c.*; also p. 219); the compound is burnt by heating with PbO, CuO, or HgO, giving off CO_2 and leaving TiO_2 and Pb, Cu, or Hg (much heat is produced in the reaction) (W., *l.c.*).

The simplest formula that expresses the composition of Ti carbonitride is Ti_5CN_4 (W., *l.c.*; *cf.* Reinhardt, *Zeit. für anorgan. Chemie*, 1, 121). This formula is generally doubled and written $Ti(CN)_2.3Ti_3N_2$, and the substance is regarded as a compound of cyanide and nitride of Ti; Joly (*C. R.* 82, 1195) regards it as a compound of carbide and nitride of Ti, and writes the formula TiC.4TiN (or 2TiC.8TiN).

Titanium, chlorides of. Ti and Cl combine to form $TiCl_4$; by the regulated action of H on $TiCl_4$ one-fourth of the Cl can be removed and $TiCl_3$ produced; and by the further action of H on $TiCl_3$ one-third of the Cl can be removed and $TiCl_2$ produced. The V.D. of the tetrachloride has been determined, and the formula $TiCl_4$ is molecular; from the analogy of C_2Cl_6 and Si_2Cl_6 it is probable that the molecular formula of the trichloride is Ti_2Cl_6; from the analogy of $PbCl_2$ and $SnCl_2$ the formula $TiCl_2$ may be supposed to be molecular, but if the analogy of C_2Cl_4 is to be followed, the molecular formula must be Ti_2Cl_4.

TITANIC CHLORIDE $TiCl_4$. (*Titanium tetrachloride.*) Mol. w. 189·38. Melts at −25° (Haase, *B.* 26, 1052). Boils at 136·41° at 760 mm. (Thorpe, *C. J.* 37, 329). S.G. $\frac{0^{\circ}}{4^{\circ}}$ 1·76041; S.G. at b.p. 1·52223 (Thorpe, *l.c.*). V.D. 98·8 at 143° (Dumas, *A. Ch.* [2] 33, 388). S.V. 121·47 (Thorpe, *l.c.*).

Preparation.—1. TiO_2 is intimately mixed with c. half its weight of lampblack previously heated to redness in a stream of Cl, and the mixture is heated to full redness in a tube of hard glass connected with a receiver, while a stream of dry Cl is passed over it. The $TiCl_4$ which collects in the receiver is freed from Cl by shaking with Cu, Hg, or Na amalgam (Merz, *Bl.* [2] 7, 401), or by boiling for some time (Thorpe, *C. J.* 47, 119), and is then distilled. Thorpe (*l.c.*) conducted the final distillation in dry N.—2. Vapour of CCl_4, or a mixture of equal volumes of Cl and CO, is passed over TiO_2 in small lumps, heated to bright redness in a tube of hard glass connected with a receiver. The $TiCl_4$ is purified as described above (Watts a. Bell, *C. J.* 33, 443).

Properties.—A colourless liquid, solidifying at −25° (Haase, *B.* 26, 1052). Does not conduct electricity (O. v. d. Pfordten, *A.* 237, 201). Fumes in the air, rapidly absorbing moisture and solidifying to the hydrate $TiCl_4.5H_2O$ (Demoly, *A.* 72, 213). (For an apparatus for collecting $TiCl_4$ for analysis, *v.* Thorpe, *l.c.*) $TiCl_4$ is violently decomposed by water, forming HClAq, and $TiO_2.xH_2O$ some of which ppts. (*v. Reactions*, No. 8).

Reactions.—1. *Hydrogen* reduces $TiCl_4$, at a high temperature, to Ti_2Cl_6 and then to $TiCl_2$ (*v. trichloride* and *dichloride*). — 2. Mixed with *oxygen* and passed through a red-hot porcelain tube, $Ti_4O_2Cl_8$ is formed (*v. Oxychlorides*, p. 748). 3. Heated to 130° in a sealed tube with *sodium*, the chief product is $TiCl_2$, according to O. v. d. Pfordten (*A.* 237, 201); Robinson a. Hutchings (*Am.* 6, 74) say that Ti is produced in this reaction. Nilson a. Pettersson (*W.* 4, 554) obtained Ti by reducing $TiCl_4$ by Na at a very high temperature.—4. *Sodium-amalgam* produces Ti_2Cl_6 and $TiCl_2$ (O. v. d. P., *l.c.*).—5. Reduced *silver* gives Ti_2Cl_6 and Ti when heated with $TiCl_4$ to 180° (Friedel a. Guérin, *A. Ch.* [5] 7, 24).—6. By passing vapour of $TiCl_4$ over *silicon, boron,* or several *metals*, heated to bright redness, Lévy (*C. R.* 110, 1368) obtained hard, steel-white, cubical crystals which he supposed to be nearly pure Ti.—7. Pure, dry, *hydrogen sulphide* reacts at the ordinary temperature, forming Ti_2Cl_6; at a higher temperature a pp. is produced which is probably a thiochloride of Ti (O. v. d. P., *A.* 234, 257).—8. Cold *water* reacts violently with $TiCl_4$, with production of much heat and formation of a turbid liquid containing HCl and holding in suspension $2TiO_2.H_2O$ (*v. Metatitanic acid* under TITANIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, p. 747); after 30 or 40 hours the liquid becomes clear, but ppn. occurs again on heating to c. 85° when about 7 pts. water are present to 1 pt. $TiCl_4$ used (*v.* Thorpe, *C. J.* 47, 120; and *cf.* TITANIUM OXYACIDS, p. 746). According to Merz (*Bl.* [2] 7, 401), an oxychloride, approximately $TiCl_4.3TiO_2.16H_2O$, is obtained by evaporating $TiCl_4Aq$, or $TiCl_4$ that has deliquesced in air, over H_2SO_4 and CaO (*v. Oxychlorides*, p. 748). TiO_2, in the form of *brookite*, is obtained by passing vapour of $TiCl_4$ and *water*, mixed with CO_2, through a red-hot porcelain tube (Daubrée, *C. R.* 29, 227; 39, 153).—9. With *hydrochloric acid* the compounds $TiCl_3.OH$ and $TiCl_2(OH)_2$ are formed (*v.* TITANIUM HYDROXYL CHLORIDES, p. 743).—10. *Chlorosulphonic acid* ($SO_2.OH.Cl$) reacts with $TiCl_4$ at the ordinary temperature to form a yellow, amorphous, deliquescent powder, having the composition $TiCl_4.SO_3$ ($= TiCl_3.OSO_2.Cl$) (Clausnizer, *B.* 11, 2011).—11. By passing vapour of $TiCl_4$, mixed with H, through a white-hot tube containing *titanium dioxide* the oxychloride $Ti_2O_2Cl_2$ is obtained (*v. Oxychlorides*, p. 748).

Combinations.—1. With *water* to form a pentahydrate and a dihydrate. Demoly (*A.* 72, 213) obtained $TiCl_4.5H_2O$, as deliquescent crystals, by allowing $TiCl_4$ to absorb moisture from the air, then adding a little more water, and evaporating under reduced pressure. By drying the pentahydrate over H_2SO_4 *in vacuo*, D. obtained $TiCl_4.2H_2O$.—2. With *ammonia*, to form $TiCl_4.4NH_3$ according to H. Rose (*P.* 16, 57), $TiCl_4.6NH_3$ according to Persoz (*A. Ch.* [2] 46, 315); easily decomposed in air; heated in a tube gives off NH_3, then NH_3 and HCl, and a yellowish sublimate of $TiCl_4.3NH_4Cl$, and leaves Ti; heated in NH_3 gives Ti_3N_4 (*v.* TITANIUM NITRIDES, p. 743). 3. With *hydrogen phosphide*, to form a brown powder, which when heated gives a sublimate of $3TiCl_4.2PH_4Cl$ according to H. Rose (*P.* 42, 527). 4. With *hydrogen cyanide* to form $TiCl_4.2HCN$ (Wöhler, *A.* 73, 226); by vaporising this compound through a red-hot tube Ti_3N_4 and C are formed (W., *l.c.*).—5. With *cyanogen chloride*, to form yellow crystals of $TiCl_4.CNCl$; sublimable at 100° (W., *A.* 73, 219).—6. With *phosphorus* *pentachloride* to form $TiCl_4.PCl_5$; obtained by heating $TiCl_4$ and PCl_5 to 150° in a sealed tube (Bertrand, *Bl.* [2] 33, 565); also by heating TiO_2 and PCl_5 in the ratio $TiO_2:3PCl_5$, or by saturating a mixture of $TiCl_4$ and PCl_3 with Cl (Tüttscheff, *A.* 141, 111), and removing excess of $TiCl_4$ by heating in a stream of Cl (Weber, *P.* 132, 452). A citron-yellow, loose, semi-crystalline solid; sublimes without melting; deliquescent in air.—7. With *phosphorus trichloride* to form yellow crystals of $TiCl_4.PCl_3$, melting at 85·5° (Bertrand, *l.c.*).—8. With *sulphur tetrachloride*, to form $2TiCl_4.SCl_4$; obtained by saturating a mixture of $TiCl_4$ and S_2Cl_2 with Cl, and warming in a stream of Cl (Weber, *P.* 132, 454).—9. By mixing $TiCl_4$ and *sulphurous chloride* H. Rose obtained large yellow crystals, probably a compound of the two chlorides (*P.* 42, 527).—10. With *ammonium chloride*, to form $TiCl_4.3NH_4Cl$ (*v. supra, Combinations*, No. 2).—11. With *phosphoryl chloride* to form $TiCl_4.POCl_3$; obtained by gradually adding $POCl_3$ to $TiCl_4$, and gently warming (Weber, *P.* 132, 453); colourless, deliquescent crystals, melting at 110°, and boiling at 140° (Wehrlin a. Giraud, *C. R.* 85, 288).—12. With *selenion oxychloride* to form a yellow powder, decomposed by heat, having the composition $TiCl_4.2SeOCl_2$; obtained by adding $SeOCl_2$ to $TiCl_4$, and drying the solid that separates on cooling on a tile over H_2SO_4 (Weber, *B. B.* 1865. 154).—13. With *nitrosyl chloride*; obtained by saturating $TiCl_4$ with NO_2, and subliming (Hampe, *A.* 126, 47), also by passing the vapours from *aqua regia* into $TiCl_4$ (Weber, *P.* 118, 476). Hampe (*l.c.*) gives the composition $3TiCl_4.4NOCl$, Weber (*l.c.*) the composition $TiCl_4.2NOCl$. A deep citron-yellow, crystalline mass; decomposes in air; sublimable out of air; with water gives off NO.—14. With *sulphur trioxide* to form $TiCl_4.SO_3$ (or $TiCl_3.OSO_2.Cl$), formed by the interaction of $TiCl_4$ and $SO_2.OH.Cl$ at the ordinary temperature; a yellow, amorphous, deliquescent powder (Clausnizer, *B.* 11, 2011).—15. Demarçay (*Bl.* [2] 20, 127) obtained a great many compounds of $TiCl_4$ with *esters*, *mercaptans*, and *ethyl sulphide* (*cf.* Bedson, *C. J.* 29, 309).

TITANIUM TRICHLORIDE Ti_2Cl_6. (*Titanium sesquichloride. Titanous chloride.*) Mol. w. not determined; but from analogy of C_2Cl_6 and Si_2Cl_6 the formula Ti_2Cl_6 is probably molecular.

Formation.—1. By reducing $TiCl_4$ by H (*v. Preparation*).—2. By reducing $TiCl_4$ by sodium-amalgam (O. v. d. Pfordten, *A.* 237, 201); or by pure, dry H_2S (O. v. d. P., *A.* 234, 257).—3. By heating $TiCl_4$ with reduced Ag to 180°; Ti is also formed, and probably $TiCl_2$ also (Friedel a. Guérin, *A. Ch.* [5] 8, 24).—4. A solution of Ti_2Cl_6 is obtained by digesting a solution of $TiO_2.xH_2O$ in HClAq with Cu at 40°-50° (Fuchs, *A.* 56, 319); or with Ag ppd. by zinc from AgCl (von Kobell, *P.* 62, 599). Ti_2Cl_6 is also probably present in the greenish liquid obtained by adding Na amalgam to K_2TiF_6 in HClAq (O. v. d. P., *A.* 237, 201).

Preparation.—$TiCl_4$ is placed in a retort connected with a tube of porcelain or hard glass (if a glass tube is used it should be wrapped in copper-foil) which is placed horizontally in a furnace; the other end of the tube projects considerably out of the furnace and is connected with a receiver to collect undecomposed $TiCl_4$. The delivery tube from an apparatus evolving pure and dry H passes into the retort beneath the surface of the $TiCl_4$. H is passed through the apparatus until it is entirely filled with the gas; the tube is then heated to redness, and the retort is gently warmed. Ti_2Cl_6 is formed and condenses as dark-violet scales on the part of the tube that projects out of the furnace. When all the $TiCl_4$ has been driven out of the retort, the Ti_2Cl_6 in the cooler part of the tube is gently warmed, while the passage of H is continued, to remove any adhering $TiCl_4$; the Ti_2Cl_6 is allowed to cool in the stream of H (Ebelmen, *A. Ch.* [3] 20, 385).

Properties.—A dark-violet, very lustrous solid, deliquescing in air, and dissolving in water to form a violet liquid, which gradually decolourises with ppn. of $TiO_2.xH_2O$. Ti_2Cl_6 is easily soluble in alcohol, forming a violet or green liquid; it is insoluble in ether, and sparingly soluble in HClAq (O. v. d. P., *A.* 237, 201).

Reactions.—1. Heated in *hydrogen* to c. 440°, $TiCl_4$ distils over and $TiCl_2$ remains (Friedel a. Guérin, *A. Ch.* [5] 8, 24).—2. Heated in *air*, $TiCl_4$ vaporises and TiO_2 remains.—3. Dissolves in *water*, forming a violet, or green-violet, liquid which slowly becomes colourless with ppn. of $TiO_2.xH_2O$.—4. *Alkalis*, or *alkali carbonates*, in solution ppt. $Ti_2O_3.xH_2O$ from Ti_2Cl_6Aq; *ammonium sulphide* forms the same pp.; *hydrogen sulphide* gives no pp. (Ebelmen, *l.c.*).—5. Ti_2Cl_6Aq reduces *solutions of gold, silver, or platinum salts* with ppn. of the metals; *ferric* and *cupric salts* are reduced to ferrous and cuprous salts; *sulphurous acid solution* is reduced by heating with Ti_2Cl_6Aq with ppn. of S (E., *l.c.*).—6. Ti_2Cl_6 reacts with *bromine* to form a liquid boiling at 154°, probably $TiBrCl_3$ (F. a. G., *l.c.*).

Combinations.—With *water* to form $Ti_2Cl_6.8H_2O$; obtained by Glatzel (*B.* 9, 1829) by evaporating a solution of Ti in HClAq to the crystallising point, filtering off ppd. $TiO_2.xH_2O$ from time to time. The hydrate is a green solid; it dissolves in water, forming an opalescent violet solution containing a little suspended $TiO_2.xH_2O$; the solution becomes colourless on standing, and then gives the reactions of titanic acid.

TITANIUM DICHLORIDE $TiCl_2$. (Sometimes called *titanous chloride.*) Mol. w. is not known. From the analogy of $SnCl_2$ and $PbCl_2$, the formula $TiCl_2$ would be molecular; but from the analogy of C_2Cl_4 the molecular formula would be Ti_2Cl_4.

Formation.—1. By reducing Ti_2Cl_6 by H (*v. Preparation*).—2. $TiCl_2$ is probably formed, along with Ti_2Cl_6, by heating $TiCl_4$ with reduced Ag (Friedel a. Guérin, *A. Ch.* [5] 8, 24).—3. Along with Ti_2Cl_6, by the action of Na amalgam on $TiCl_4$; also by heating $TiCl_4$ with Na to 130° in a sealed tube (O. v. d. Pfordten, *A.* 237, 201).

Preparation.—Ti_2Cl_6 reacts with H at a red heat to give $TiCl_2$ and $TiCl_4$. Friedel a. Guérin (*l.c.*) proceed as follows. The tube containing Ti_2Cl_6, prepared from $TiCl_4$ (*v. supra*), while still filled with H, is connected with an apparatus evolving pure, dry CO_2, and the whole of the H in the apparatus is driven out by CO_2. The Ti_2Cl_6 is then shaken into a small tubulated retort, placed on a sand-tray, and previously filled with CO_2; the CO_2 is displaced by pure, dry H; the retort is then heated to dull red.

ness, while a stream of H is passed through it, until $TiCl_4$ ceases to distil off; the retort is allowed to cool in the stream of H, and CO_2 is then passed in until all the H is removed (if this is omitted the $TiCl_2$ takes fire in the air), and the black $TiCl_2$ in the retort is quickly shaken into small dry tubes filled with CO_2, which are at once sealed off.

Properties.—A black, light powder; very rapidly absorbs water, forming a kind of mud; insoluble in CS_2, $CHCl_3$, or Et_2O. Volatilised without melting by heating to full redness in H. Shaken with Et_2O and KCNSAq, the Et_2O becomes dark brown; this is a delicate test for $TiCl_2$ (O. v. d. Pfordten, *A.* 237, 201).

Reactions.—1. Takes fire when touched with a drop of *water* (? with formation of $Ti_2O_2Cl_2$; *v.* F. a. G., *l.c.*); thrown into water, it hisses like red-hot iron, decomposing the water with evolution of H and formation of a yellowish liquid.—2. Decomposes absolute *alcohol*, giving off H and forming a yellowish liquid.—3. Heated in *air*, $TiCl_2$ burns like tinder, giving off $TiCl_4$ and leaving TiO_2.—4. With *bromine* it forms a liquid boiling at 176°, probably $TiCl_2Br_2$ (F. a. G., *l.c.*).

Titanium, chlorobromides of, *v.* TITANIUM BROMOCHLORIDES, p. 739.

Titanium, cyanonitride of, *v.* TITANIUM CARBONITRIDE, p. 739.

Titanium, ferrocyanides of, *v.* vol. ii. p. 337.

Titanium, fluorides of. The only compound that has been isolated with certainty is TiF_4. There are indications of the existence of Ti_2F_6, and compounds of this fluoride with alkali fluorides are known.

TITANIC FLUORIDE TiF_4. (*Titanium tetrafluoride.*) Formula probably molecular, from analogy of $TiCl_4$ and TiI_4. By heating a mixture of TiO_2 and CaF_2 with H_2SO_4, Unverdorben (*P.* 7, 320) obtained a colourless distillate, which he supposed to contain a compound of Ti and F. Berzelius (*P.* 4, 1) obtained crystals (? TiF_4) by dissolving $TiO_2.xH_2O$ in HFAq. The crystals were decomposed by water, giving an acid solution (? H_2TiF_6Aq), and an insoluble, 'so to say *basic*,' compound. TiO_2 is obtained by passing vapour of TiF_4, mixed with H_2O, through a tube heated to c. 800° or 1000° (Hautefeuille, *A. Ch.* [4] 4, 131; *cf.* TITANIUM DIOXIDE, p. 741). Heated to redness in H, perhaps gives Ti_2F_6 (H., *l.c.*).

Combinations.—1. TiF_4 probably combines with *hydrogen fluoride* to form H_2TiF_6. By dissolving $TiO_2.xH_2O$ in HFAq, evaporating, adding water to the crystals (? TiF_4) thus formed, and filtering from an insoluble solid (? oxyfluoride), Berzelius (*P.* 4, 1) obtained an acid solution from which, by neutralisation with KOHAq and evaporation, he obtained the salt K_2TiF_6. The acid solution probably contained H_2TiF_6. This compound (if it exists) is best called *titanifluorhydric acid*. It is analogous to H_2SiF_6, H_2SnF_6, and other acids of the type H_2MX_6, where M = an element of Group IV. (except C), and X = a halogen.—2. With various *metallic fluorides* to form $TiF_4.2MF = M_2TiF_6$. These salts were obtained from the K salt, which was got by neutralising the acid solution prepared as described under 1. Salts of NH_4, Ca, Cu, Fe, Pb, Mg, and Ni are described (B., *l.c.*; Weber, *P.* 120, 291). These salts are best called *titanifluorides*; they are similar to stannifluorides.—3. TiF_4 also combines with *ammonium fluoride* to form $TiF_4.3NH_4F$ (besides $TiF_4.2NH_4F$) (Baker, *C. J.* 35, 763).

By adding NH_3Aq, drop by drop, to warm $(NH_4)_2TiF_6Aq$, Piccini (*G.* 17, 479) obtained a compound of the form $TiO_2F_2.xNH_4F$; from this he prepared $TiO_2F_2.BaF_2$, and by carefully decomposing this salt by H_2SO_4Aq he obtained a solution of the acid $TiO_2F_2.2HF$. P. regards this acid as a F derivative of the hypothetical *pertitanic acid* H_2TiO_4 (the acid of TiO_3); he calls the acid *fluoroxypertitanic acid*, and the salts *fluoroxypertitanates*. Following the plan adopted in this *Dictionary*, the acid will be called *titanoxyfluorhydric acid* $H_2TiO_2F_4$, and the salts, $M^I_2TiO_2F_4$, will be called *titanoxyfluorides*. $H_2TiO_2F_4Aq$ is a yellow liquid, not ppd. by Ba salts, giving a pp. of TiO_3 with alkali carbonates.

TITANIUM TRIFLUORIDE Ti_2F_6. This compound is said to be formed by strongly heating K_2TiF_6 in a stream of H with a little HCl, according to Hautefeuille (*C. R.* 59, 189; *cf.* 57, 151). According to H., the compound is a purple-red solid, soluble in water. By treating Ti_2Cl_6Aq with KHF_2 or NH_4F, Piccini (*G.* 16, 104) obtained violet pps. of $Ti_2F_6.2MF$, where M = NH_4 or K; he also obtained $Ti_2F_6.3NH_4F$. The K salt is slightly soluble in water; soluble in dilute acids, forming green liquids, from which alkalis throw down azure-blue pps. that gradually oxidise to $TiO_2.xH_2O$ on exposure to air. The salt $TiF_4.3NH_4F$, when exposed to air, gradually oxidises to $TiO_2F_2.3NH_4F$.

Titanium, haloid compounds of. Ti combines with the halogens directly to form compounds TiX_4; these tetrahalides are generally prepared by passing the halogen as gas over a red-hot mixture of TiO_2 and C. TiI_4 is best prepared by heating $TiCl_4$ in HI gas, and $TiBr_4$ is very conveniently prepared by heating $TiCl_4$ in HBr gas; TiF_4 is prepared by dissolving $TiO_2.xH_2O$ in HFAq and evaporating. The two tetrahalides $TiCl_4$ and TiI_4 have been gasified. These formulæ are molecular, hence the formulæ TiF_4 and $TiBr_4$ probably also represent the compositions of the gaseous molecules of these compounds. By the action of H, or certain other reducing agents, on $TiCl_4$, two chlorides are obtained, Ti_xCl_{3x} and Ti_xCl_{2x}. The V.D. of neither has been determined, but from the analogy of C_2Cl_6 and Si_2Cl_6, the value of x in Ti_xCl_{3x} is probably 2; from the analogy of C_2Cl_4 the molecular formula of the lowest chloride is probably Ti_2Cl_4, but from the analogy of $SnCl_2$ and $PbCl_2$ the formula $TiCl_2$ would be given to it. Ti_2F_6 or TiF_3 probably exists. No bromide or iodide of either type Ti_2X_6 or Ti_2X_4 has been isolated. Two bromochlorides of the types TiX_4 and Ti_2X_4 probably exist. $TiCl_4$ and $TiBr_4$ dissolve in cold water; the solutions contain HXAq and $TiO_2.xH_2O$; dilution, and more quickly heating, ppts. insoluble $TiO_2.xH_2O$ from the solution of $TiCl_4$. TiF_4 is decomposed by water, giving H_2TiF_6Aq (and ? an oxyfluoride). TiI_4 is also decomposed by water; on heating insoluble $TiO_2.xH_2O$ separates. $TiCl_4$ combines with many non-metallic chlorides and oxychlorides. TiF_4 combines with metallic fluorides, forming salts M_2TiF_6, and also some more complex salts $xTiF_4.yMF$. A few *oxyhaloid compounds* have been isolated, but a great number can doubtless be formed. The acid $H_2TiO_2F_4$ and salts of this acid have been isolated. Ti_2Cl_6 dissolves in water, and after a time $TiO_2.xH_2O$ separates; the solution is an energetic reducing agent; alkalis ppt. $Ti_2O_3.xH_3O$. $TiCl_2$ reacts violently with water, giving off H, and probably forming an oxychloride.

Titanium, hydroxyl chlorides of. By the reaction of the proper quantity of 36 p.c. HClAq with $TiCl_4$, the compound $Ti(OH)Cl_3$ was obtained by Koenig a. O. v. d. Pfordten (*B.* 21, 1708); using the calculated quantity of 36 p.c. HClAq, the compound $Ti(OH)_2Cl_2$ was produced; and the prolonged action of ordinary air on either of the preceding compounds resulted in the formation of $Ti(OH)_3Cl$. These compounds are regarded by K. a. O. v. d. P. as derived from $Ti(OH)_4$ by replacement of OH by Cl; the compounds may be called *orthotitanic chlorhydrins.* The compounds are yellow or white deliquescent solids; they dissolve in water; $Ti(OH)Cl_3$ very rapidly with a hissing noise, $Ti(OH)_2Cl_2$ less violently, and $Ti(OH)_3Cl$ with some difficulty. The aqueous solutions give pps. of $TiO_2.xH_2O$ on boiling. When the compounds are heated they give (1) $TiCl_4$ and $TiO_2.xH_2O$, (2) $TiO_2.xH_2O$ and HCl, and (3) $TiO_2.xH_2O$, HCl, and H_2O. By reducing $Ti(OH)Cl_3$ by Na amalgam, in H, Ti_2O_3 is produced (K. a. O. v. d. P., *B.* 22, 2070; *cf.* *B.* 22, 1485).

Titanium, hydroxyl fluoride of. This name may be given to the compound $Ti(OH)_2F_4$; it is described as *titanoxyfluorhydric acid,* under TITANIC FLUORIDE (p. 742).

Titanium, iodides of. Only one compound has been isolated, TiI_4.

TITANIC IODIDE TiI_4. (*Titanium tetraiodide.*) Mol. w. 554·02. V.D. at 440° = 261·2 (Hautefeuille, *Bl.* [2] 7, 201).

Formation.—1. Vapour of I is passed over Ti heated to redness (Weber, *P.* 120, 287).—2. A mixture of $TiCl_4$ vapour, I vapour, and H is passed through a tube heated to dull redness; TiI_4, mixed with free I, condenses on the colder part of the tube (Hautefeuille, *Bl.* [2] 7, 201).—3. By decomposing $TiCl_4$ by HI.

Preparation.—Dry HI gas is passed into $TiCl_4$, which is gradually heated to its b.p. and kept at that temperature until the reaction is completed; the TiI_4 is freed from traces of I, which give it a violet tinge, by a few distillations in H (H., *l.c.*).

Properties and Reactions.—A reddish-brown, lustrous, brittle solid; when melted and cooled, crystallises in octahedra, changing after some days to tufts of silky, prismatic crystals. Melts at 150°, and boils a little above 360°; can be distilled without decomposition; melted TiI_4 remains liquid till cooled below 100°. Fumes strongly in the air. Dissolves easily in water; solution turns brown on exposure to air and ppts. $TiO_2.xH_2O$. When vapour of TiI_4 is heated in air it burns to TiO_2 and I_2O_5 (H., *l.c.*).

Titanium, nitrides of. Four compounds of Ti and N have been described; but according to later experiments only two seem to exist.

TRITITANIUM TETRANITRIDE Ti_3N_4. Mol. w. unknown. This compound is obtained by heating $TiCl_4.4NH_3$ (*v.* TITANIC CHLORIDE, *Combinations,* No. 2, p. 740), loosely packed in a tube of hard glass, in a stream of dry NH_3, until the glass begins to melt, and allowing to cool in NH_3 (Wöhler, *A.* 73, 43; Friedel a. Guérin, *A. Ch.* [5] 8, 24). Indigo-blue powder, or golden-yellow (? rhombohedral) crystals; strongly heated in H gives Ti_2N_2 (F. a. G., *l.c.*).

DITITANIUM DINITRIDE Ti_2N_2. Mol. w. unknown. Prepared by placing two porcelain boats, one containing Na and the other K_2TiF_6, in a hard-glass tube previously filled with N, passing a stream of dry N through the tube, heating the K_2TiF_6 to full redness while the Na is volatilised over it, and allowing to cool in N after all the Na has been volatilised; boiling with HClAq, washing, and drying (Wöhler a. Deville, *A.* 102, 234). Also obtained by heating K_2TiF_6 with K, KCl, NaCl, and Al in N; also by passing $TiCl_4$ vapour and H over heated Al, in N; also by passing vapour of $TiCl_4$ over heated NH_4Cl (W. a. D., *l.c.*). F. a. G. (*l.c.*) obtained the same compound by strongly heating TiO_2 in a stream of dry NH_3 for some hours; W. (*A.* 73, 43) said that TiN_2 was formed by this reaction. F. a. G. also obtained Ti_2N_2 by strongly heating Ti_3N_4 in H; W. said that Ti_5N_6 was formed by this reaction. An amorphous, brown-yellow, very hard powder; S.G. 5·28 at 18° (F. a. G., *l.c.*).

The nitrides of Ti are not decomposed by heating, out of air, to c. 950°-1,000°; fused with KOH, or strongly heated in steam (F. a. G., *l.c.*), they give off NH_3; heated in Cl, $TiCl_4$ is produced (F. a. G., *l.c.*); heated with CuO, PbO, or HgO, the nitrides burn, and Cu, Pb, or Hg is produced (W., *A.* 123, 34).

TITANIUM DINITRIDE TiN_2. This compound is formed, according to Wöhler (*A.* 73, 43), by heating TiO_2 in NH_3 for some time. Friedel a. Guérin (*A. Ch.* [5] 8. 24) say that the substance obtained by W. contained Ti_2O_3, and that if the heating is continued until a definite nitride is formed the compound so produced is Ti_2N_2.

PENTATITANIUM HEXANITRIDE Ti_5N_6. Formed, according to W. (*l.c.*), by heating Ti_3N_4 to full redness in H; or, mixed with C, by heating TiO_2 in CN or HCN gas. F. a. G. (*l.c.*) say that the product of either reaction is Ti_2N_2, in the latter reaction mixed with C.

Titanium, nitrocyanide of, *v.* TITANIUM CARBONITRIDE (p. 739).

Titanium, oxides and hydrated oxides of (*cf.* TITANIUM OXYACIDS AND SALTS AND DERIVATIVES THEREOF, p. 746). Ti burns when heated in O, forming TiO_2; by the reaction of reducing agents on $TiCl_4Aq$, and addition of alkalis, Ti_2O_3 is obtained; when the reduction is carried further it is probable that $TiO.xH_2O$ is formed. By the reaction of H_2O_2Aq in presence of alkali on salts of TiO_2, a pp. of TiO_3 is obtained. Oxides intermediate between TiO_2 and Ti_2O_3 probably exist. TiO_2 is a basic oxide, forming salts TiX_4, where $X = NO_3$, $\frac{1}{2}SO_4$, &c.; many of the salts are basic. A few salts corresponding with Ti_2O_3 have been isolated; no salt corresponding with TiO and derived from an oxyacid has yet been obtained. Some of the hydrates of TiO_2 react as feeble acids.

TITANIUM DIOXIDE TiO_2. (*Titanic oxide. Titanic anhydride.*) Mol. w. unknown.

Occurrence.—As *rutile*, *anatase*, and *brookite*; *rutile* occurs in dimetric prisms, isomorphous with *tinstone*; *anatase* in dimetric octahedra; and *brookite* in trimetric octahedra.

Formation.—1. By burning Ti in air or O.—2. By ppg. $TiCl_4Aq$ by alkali, and washing, drying, and strongly heating the ppd. $TiO_2.xH_2O$.—3. By ppg. K_2TiF_6Aq by NH_3Aq, and strongly heating the pp. after washing and drying.—4. Vapour of $TiCl_4$, or TiF_4, mixed with steam is passed through a red-hot tube.—5. TiS_2 is heated in dry CO_2 ($TiS_2 + 2CO_2 = TiO_2 + 2CO + 2S$; O. v. d. Pfordten, *B.* 22, 2070).

Preparation.—A. Amorphous titanic oxide.—1. Pure $TiCl_4$ is added, little by little, to water; sufficient NH_3Aq to neutralise the HCl produced is added, the solution is evaporated to dryness, and the residue is heated to somewhat above 700° until it ceases to lose weight. $TiCl_4$ may be obtained from *rutile* by mixing the finely-powdered mineral with c. half its weight of dry charcoal-powder, making into little pellets with starch-paste, drying the pellets, heating them to full redness in a covered crucible, then heating in a tube of hard glass (to get quite dry), and then passing dry Cl over the pellets while they are heated to bright redness, and a dry receiver is connected with the end of the hard glass tube. The $TiCl_4$ may be purified (from $SiCl_4$, $FeCl_3$, &c.) by repeatedly distilling, best in a stream of N (*v.* Merz, *J. pr.* 99, 161).—2. K_2TiF_6 is dissolved in water, NH_3Aq is added, the pp. of $TiO_2.xH_2O$ is thoroughly washed, dried, and heated to somewhat above 700°. (For a method of getting K_2TiF_6 from *rutile v. Preparation of titanium*, p. 738.) For other methods of preparing TiO_2 from Ti ores *v.* Lévy (*A. Ch.* [6] 25, 511), Austen a. Wilber (*Am.* 4, 211), Hempel (*Zeit. f. anorg. Chemie*, 3, 193), Jones (*Fr.* 9, 41, 330). B. Crystalline titanic oxide.—3. By long-continued heating to whiteness TiO_2 is said to become crystalline (*v.* Rammelsberg, *B.* 5, 1006).—4. Amorphous $TiO_2.xH_2O$ is heated to incipient redness in HCl gas, at a pressure of three atmospheres; the crystals have the form of *anatase* (Hautefeuille a. Perrey, *C. R.* 110, 1038).—5. Crystalline TiO_2 is also formed, according to Hautefeuille (*A. Ch.* [4] 4, 127), by passing the mixed vapours of TiF_4, HF, and HCl—obtained by decomposing molten K_2TiF_6 by HCl gas—through a Pt tube into which a stream of moist H is also passed; at c. 860° (boiling-point of Cd) crystals of *anatase* are produced, and at temperatures between 860° and 1,000° *brookite* is formed.—6. Heating amorphous TiO_2 in an atmosphere of HF causes crystallisation; at an incipient red heat *anatase* forms, at a higher temperature *brookite*, and at a very high temperature *rutile* (H., *l.c.*).—7. Crystals of *rutile* are formed by heating amorphous TiO_2 with microcosmic salt (Ebelmen, *A. Ch.* [3] 33, 34), or with borax (G. Rose, *B. B.* 1867. 129; Knop, *A.* 157, 365), in a porcelain oven. For other methods of producing crystals of TiO_2 *v.* Deville (*C. R.* 53, 161, 163), Senarmont (*A. Ch.* [3] 30, 129), Michel (*C. R.* 115, 1020), Wöhler (*A.* 73, 35), Daubrée (*C. R.* 29, 227; 39, 153), H. Rose (*A.* 56, 127; 68, 163).

Properties.—TiO_2 obtained by strongly heating $TiO_2.xH_2O$ forms reddish-brown lumps, more nearly resembling rutile in colour and lustre the higher the temperature to which it is heated. The dehydration by heat of $TiO_2.xH_2O$ is accompanied by the appearance of shades of colour from white, though grey and greenish, to black, according to Wagner (*B.* 21, 960); these colours are similar to those shown by *anatase*, *brookite*, and *rutile*. Nilson a. Pettersson (*Z. P. C.* 1, 33 *note*) prepared TiO_2 as a white powder with faintest yellow tinge, by decomposing $TiCl_4$ by NH_3Aq, evaporating, and heating to whiteness. When melted by the O-H flame the colour is blue to black. S.G. TiO_2 increases as the oxide is heated; heated to c. 700° S.G. is c. 3·95 (Karsten, *S.* 65, 394), after being very strongly heated S.G. rises to 4·25 (Ebelmen, *J.* 4, 15; 12, 14). S.G. of *anatase* is 3·75 to 3·9 (Breithaupt, *J.* 2, 730; Damour, *J.* 10, 666); S.G. of *brookite* is 4 to 4·2 (Rammelsberg, *J.* 2, 730; Beck, *J.* 3, 704); S.G. of *rutile* is c. 4·3 (Scheerer, *P.* 65, 296; Müller, *J.* 5, 847). After fusion in the O-H flame and cooling S.G. is 4·1, according to Hautefeuille (*A. Ch.* [4] 40, 140). S.H. 0° to 100° = ·1785, 0°-211° = ·1791, 0°-301° = ·1843, 0°-440° = ·1919° (Nilson a. Pettersson, *Z. P. C.* 1, 27; TiO_2 prepared by decomposing $TiCl_4$ by NH_3Aq, evaporating to dryness, and heating to white heat). TiO_2 crystallises in dimetric prisms (*rutile*), dimetric octahedra (*anatase*), and trimetric octahedra (*brookite*); it is isotrimorphous with SnO_2 (Wunder, *J. pr.* [2] 2, 206). TiO_2 is somewhat hygroscopic, even after prolonged and intense heating (Thorpe, *C. J.* 47, 125). It is insoluble in water, and in all acids except conc. H_2SO_4; when powdered TiO_2 is heated with conc. H_2SO_4 until the excess of acid is removed, the solid thus produced dissolves in water. TiO_2 melts in the O-H flame. According to Moissan (*C. R.* 115, 1034), when heated in an electric furnace to c. 2500° TiO_2 forms black crystals of TiO.

Reactions.—1. According to Ebelmen (*A. Ch.* [3] 20, 394), TiO_2 is reduced to Ti_2O_3 by heating to redness in *hydrogen*; but O. v. d. Pfordten (*A.* 237, 201) says the product has the composition Ti_7O_{12}.—2. A mixture of TiO_2 and *magnesium* powder heated to redness in H gives $MgTiO_3$, and a brown powder which is probably TiO (Winkler, *B.* 23, 2657).—3. A mixture of TiO_2 and *carbon* strongly heated in *chlorine* gives $TiCl_4$.—4. By long-continued heating in dry *ammonia* Ti_2N_2 is formed (Friedel a. Guérin, *A. Ch.* [5] 8, 24).—5. The compound $TiCl_4.PCl_5$ is obtained by heating an intimate mixture of TiO_2 and *phosphorus pentachloride*, in the ratio $TiO_2:3PCl_5$, in a retort until the $POCl_3$ formed is driven off (Weber, *P.* 132, 452).—6. Heated to redness in *carbon tetrachloride* vapour, $TiCl_4$ is formed (Watts a. Bell, *C. J.* 33, 443). Demarçay (*C. R.* 104, 111) says that the first product is $TiOCl_2$.—7. $TiCl_4$ is formed by heating TiO_2 to redness in a mixture of equal volumes of *chlorine and carbon monoxide* (W. a. B., *l.c.*).—8. Ti_2N_2 mixed with C is formed by heating TiO_2 in *cyanogen* or in *hydrogen cyanide* (Friedel a. Guérin, *A. Ch.* [5] 8, 24).—9. Heating in a mixture of *hydrogen sulphide and carbon disulphide* forms Ti_2S_3 or TiS_2, according to the temperature (Thorpe, *C. J.* 47, 491).—10. When TiO_2 is fused with *sodium* or *potassium carbonate* the weight of CO_2 expelled corresponds with the formation of M_2TiO_3; on treating the fused mass

with water MOHAq is formed, and an acid Na or K titanate which is insoluble in water (*v.* Hermann, *J. pr.* 38, 92).—11. Fusion with *potassium hydrogen sulphate* forms a substance soluble in water; by evaporating the fused mass with conc. H_2SO_4, and then treating with water, the double salt $Ti(SO_4)_2.K_2SO_4.3H_2O$ is obtained (Warren, *P.* 102, 449; Glatzel, *B.* 9, 1833; Hermann, *l.c.*).—12. Heating powdered TiO_2 with *conc. sulphuric acid* produces a substance that dissolves wholly in water (? forming $Ti(SO_4)_2.xH_2O$ or $TiO.SO_4$; *v.* Merz, *J. pr.* 99, 157). For reactions of $TiO_2.xH_2O$ *v. infra, hydrated titanic oxide*; and *v.* also *titanic acid* under Titanium oxyacids and salts and derivatives thereof, p. 746).

Hydrated titanic oxide. Hydrates of TiO_2 are obtained by gradually adding $TiCl_4$ or $TiBr_4$ to cold NH_3Aq; by fusing TiO_2 with $KHSO_4$, dissolving in water, diluting, and boiling for some time; by adding water to $TiCl_4$ and boiling; by fusing TiO_2 with K_2CO_3, washing the fused mass with small quantities of water till all KOH is removed, adding a little conc. HClAq, filtering cold, and allowing the liquid to stand, when it gradually deposits gelatinous $TiO_2.xH_2O_6$ (O. v. d. Pfordten, *B.* 17, 727); by decomposing $Ti(OEt)_4$ by H_2O (Demarçay, *C. R.* 80, 51); and by other reactions. The isolation of a great many definite hydrates of TiO_2 has been announced from time to time. By decomposing $TiCl_4.PCl_5$ (*v.* Titanic chloride, *Combinations*, No. 6, p. 740) by the action of moist air, and drying over H_2SO_4, Tüttscheff (*A.* 141, 111) said that the *dihydrate* $TiO_2.2H_2O$ was formed, and by drying this at 110°–120° he said that the *monohydrate* $TiO_2.H_2O$ was obtained. According to Carnelley a. Walker (*C. J.* 53, 66, 81), dehydration of $TiO_2.xH_2O$ (obtained by adding $TiCl_4$ to cold NH_3Aq), air-dried for 14 days, proceeds continuously from 15° to 710° whereat the whole of the water is removed. A very large number of hydrates probably exists, and these pass one into the other as temperature rises without any of them remaining unchanged through more than a few degrees.

Two classes of hydrates of TiO_2 exist; one obtained by ppg. $TiCl_4$ by NH_3Aq, or warming TiO_2 with conc. H_2SO_4, dissolving in water, diluting, and ppg. by alkali; the other obtained by dissolving hydrates of the former class in dilute acid, and boiling. Hydrates of the former class dissolve easily in dilute acids, while those of the latter class are insoluble in dilute acids (for more details *v.* Titanium oxyacids, p. 746).

Hydrated TiO_2, obtained by ppn. by alkali in the cold, dissolves in dilute acids, forming salts TiX_4, where $X = NO_3$, $\frac{1}{2}SO_4$, &c.; not many salts of this form have been isolated, and most of those that are known are basic salts. $TiO_2.xH_2O$ dissolves in molten H_3PO_4; on cooling crystals of $TiO_2.P_2O_5$ ($=TiP_2O_7$) are obtained (Hautefeuille a. Margottet, *C. R.* 102, 1017). By heating $TiO_2.xH_2O$ with a little cold conc. HClAq, pouring off the solution after a few days, and evaporating it in *vacuo*, Koenig a. O. v. d. Pfordten obtained crystals approximating to $Ti(OH)_2Cl_2$, but differing from $Ti(OH)_2Cl_2$ prepared by the interaction of $TiCl_4$ and HClAq (*B.* 22, 1485; *cf.* Titanium hydroxyl chlorides, p. 743).

Titanium sesquioxide Ti_2O_3. (*Titanous oxide.*) Mol. w. unknown. By digesting a solution of $TiO_2.xH_2O$ in HClAq with Cu at 40° to 50°, Fuchs (*A.* 56, 319) obtained a violet solution which gave a brownish black pp. with NH_3Aq; the pp. quickly reacted with water, giving off H and forming $TiO_2.xH_2O$. Von Kobell (*P.* 62, 599) obtained similar reactions by using reduced Ag in place of Cu. Ebelmen (*J. pr.* 42, 73) obtained a nearly black pp. by adding alkali to Ti_2Cl_6Aq. According to Ebelmen (*J. pr.* 42, 76) Ti_2O_3 can be prepared by heating TiO_2 to redness in perfectly dry H. Ti_2O_3 thus prepared is described as a black solid; unacted on by HNO_3 or HClAq; oxidised to TiO_2 only by heating to a very high temperature; soluble in H_2SO_4Aq, forming a violet solution. According to O. v. d. Pfordten (*A.* 237, 201), the product of reducing TiO_2 in H is not Ti_2O_3 but has the composition Ti_7O_{12}. Friedel a. Guérin (*A. Ch.* [5] 8, 38) obtained Ti_2O_3, but not free from other compounds, by passing $TiCl_4$ vapour mixed with H over TiO_2 at a red heat. They describe Ti_2O_3 as a copper-red, metal-like, microscopically crystalline powder; not acted on by boiling HNO_3Aq, but oxidised to $TiO_2.xH_2O$ by boiling H_2SO_4Aq; soluble in HFAq or warm *aqua regia*; giving off NH_3 and H with hot alkali solutions; oxidised to TiO_2 by heating to redness in air. Koenig a. O. v. d. Pfordten (*B.* 22, 2070) failed to obtain Ti_2O_3 by the method of F. a. G.

When Ti is dissolved in hot HClAq, in an atmosphere of H, the solution contains Ti_2Cl_6 (Rammelsberg, *J. pr.* 99, 176); a solution of $TiO_2.xH_2O$ in HClAq reduced by zinc also contains Ti_2Cl_6 (K. a. O. v. d. P., *l.c.*); in these solutions alkalis give black pps., probably $Ti_2O_3.xH_2O$; the pps. soon change in contact with H_2O to $TiO_2.xH_2O$, H being given off. According to O. v. d. P. (*A.* 237, 201), a solution of K_2TiF_6 in a *little* HClAq gives a pp. of $Ti_2O_3.xH_2O$ on treatment with Na-amalgam.

Sabatier a. Senderens (*C. R.* 114, 1429; 115, 236) say that Ti_2O_3 is oxidised to TiO_2 by heating to c. 500° in NO, or to c. 300° in NO_2.

Titanium monoxide TiO. This oxide has not been isolated with certainty. According to Moissan (*C. R.* 115, 1034) black prisms, which he took to be TiO, are formed by heating TiO_2 to c. 2500° in an electric furnace, and at a higher temperature the (?) TiO melts and then volatilises. By heating a mixture of TiO_2 and Mg powder to redness, in H, Winkler (*B.* 23, 2657) obtained a brown powder which probably contained some TiO, mixed with $MgTiO_3$. According to Berthier (*A. Ch.* [2] 54, 374) TiO_2 lost 6 p.c. O when heated strongly in a carbon crucible, 13 to 16 p.c. O when heated with 12 p.c. C, and 20 p.c. O when heated with 24 p.c. C (TiO_2 loses 20 p.c. O in becoming TiO); the product may have contained TiO, or it may have been a mixture of TiO_2, Ti_2O_3, and Ti.

Hydrated titanium monoxide $TiO.H_2O = TiO_2H_2$. O. v. d. Pfordten (*A.* 237, 201) obtained a black pp., said by him to be TiO_2H_2, by the continued action of Na-amalgam on a solution of K_2TiF_6 in a fair amount of HClAq (if there is little HClAq, Ti_2O_3 is ppd.); the solution became green, then colourless, and then the black pp. was formed. The black pp. formed by NH_3Aq, alkali carbonates, or $(NH_4)_2SAq$, in solutions of $TiCl_2$ (*q. v.*, p. 741) is TiO_2H_2, according

to O. v. d. P. (*l.c.*). With Na_2HPO_4Aq, and $NaC_2H_3O_2Aq$, $TiCl_2$ is said to give bluish-black and greenish-black pps., which may be salts of TiO (O. v. d. P., *l.c.*).

TITANIUM PEROXIDE. TiO_3. (*Titanium trioxide* or *superoxide.*) In 1882 (*Atti dei Lincei*, 1882. 1) Piccini dropped H_2O_2Aq into solution of $TiO_2.xH_2O$; from the quantity of H_2O_2 that reacted he concluded that an oxide TiO_3 was produced. In the same year (*B.* 15, 2599) Weller obtained a yellow pp., which reacted with HClAq, giving off Cl, by the interaction of H_2O_2Aq and freshly ppd. $TiO_2.xH_2O$ or a solution of $TiO_2.xH_2O$. In 1888, Classen (*B.* 21, 370) added $TiCl_4$, drop by drop, to dilute alcohol, then added to this solution a very large excess of H_2O_2Aq, and then KOHAq, NH_3Aq, or $(NH_4)_2CO_3Aq$; in each case he obtained a yellow liquid from which a yellow pp. separated after some time; after syphoning off the liquid, washing the pp. by decantation, and drying it on a tile, he obtained a yellow solid approximating to the composition $TiO_3.3H_2O$. In 1889, Lévy (*C. R.* 108, 294) approximately determined the composition of the pp. obtained by adding H_2O_2Aq to $TiO_2.xH_2O$ in H_2SO_4Aq, by dropping in H_2O_2Aq of known concentration, and determining the quantity of H_2O_2 used in the reaction; L. concluded that the results could be accounted for by supposing the yellow pp. to be TiO_3, $TiO_2.H_2O_2$, or $Ti_2O_5.H_2O_2$, but that probably the pp. was TiO_3. In 1893 Bailey a. Dawson (*Studies from the Phys. and Chem. Laboratories of the Owens College*, vol. i. p. 216) obtained yellow to orange solids, agreeing fairly in composition with the formula TiO_3. B. a. D. added (1) H_2O_2Aq, (2) freshly ppd. BaO_2, to $TiO_2.xH_2O$ in dilute H_2SO_4Aq, diluted the deep-red liquids thus obtained with twice their volumes of alcohol, added conc. alcoholic solution of KOH, washed the pps. with alcohol (to remove H_2O and H_2O_2), and then with ether, and, in some cases, dried in the air. According to B. a. D., TiO_3 dissolves in water, forming a deep-red liquid; this solution decolourises $KMnO_4Aq$; TiO_3 dissolves in HClAq, giving off Cl. By allowing ppd. TiO_3 to stand for some time, B. a. D. say that a modification is formed insoluble in water.

OXIDES OF TITANIUM INTERMEDIATE BETWEEN TiO_2 AND Ti_2O_3.

I. By heating TiO_2 with HCl gas in a reducing atmosphere, Deville (*C. R.* 53, 163) obtained a blue, crystalline solid, to which he gave the formula Ti_3O_5. A similar solid (? same composition) was obtained by Friedel a. Guérin (*A. Ch.* [5] 8, 44) by passing H and HCl over TiO_2 strongly heated in a porcelain tube. This blue solid is said to decompose water, in presence of strong bases, giving off H and forming TiO_2.

II. By very strongly heating TiO_2 in H, O. v. d. Pfordten (*A.* 237, 228) obtained a dark indigo-blue solid, to which he gave the formula Ti_7O_{12}; according to Ebelmen (*J. pr.* 42, 76), Ti_2O_3 is formed by this reaction. Heated in air the compound burns to TiO_2.

III. By adding alcoholic solution of KOH to a solution of $TiO_2.xH_2O$ in dilute H_2SO_4Aq, after treating the solution with BaO_2, Piccini (*Atti dei Lincei*, 1882. 1) obtained yellow pps. with compositions varying from Ti_5O_{11} to Ti_2O_5.

Titanium oxyacids and salts and derivatives thereof. The hydrates of TiO_2 react as feeble acids, besides reacting with the stronger acids as feeble bases. The salts wherein Ti forms part of the acidic radicles are generally obtained by fusing TiO_2 with salts of the metals which are to be converted into titanates. Only a very few titanates are soluble in water; several dissolve in HClAq, but on diluting and boiling most, if not all, of the $TiO_2.xH_2O$ is ppd.

TITANIC ACIDS. Hydrates of TiO_2 are obtained by various reactions (*v.* HYDRATED TITANIC OXIDE, p. 745). By drying under different conditions solids are obtained approximately corresponding with the formula $xTiO_2.yH_2O$, where $x = 1$, 2, or 3, and $y = 1, 2, 3, 4$, or 5. (For a list of the hydrates obtained by different experimenters *v.* Tüttscheff, *A.* 141, 111.) There seems to be a series of hydrates of TiO_2, all of which may be classed together under the name *titanic acids*, none of them being stable through more than a few degrees of temperature (*v.* Carnelley a. Walker, *C. J.* 53, 66, 81); the relations of composition of these acids may be expressed by such a general equation as $n\text{TiH}_4\text{O}_4 - m\text{H}_2\text{O} = \text{Ti}_n\text{H}_{4n-2m}\text{O}_{4n-m}$.

The titanic acids belong to two classes: those which are formed by decomposing $TiCl_4$ or $TiBr_4$ by dilute cold alkali solutions, or by warming TiO_2 with conc. H_2SO_4, dissolving the product in water, and ppg. by dilute cold alkali solutions; and those which are formed by decomposing $TiCl_4$ or $TiBr_4$ by water and boiling, or by dissolving titanic acids of the former class in dilute acid and boiling, or by fusing TiO_2 with $KHSO_4$, dissolving in much water and boiling. The acids of the former class are generally called *titanic acids* or *ortho-titanic acids*, and those of the latter class *meta-titanic acids*. *Orthotitanic acids* dissolve easily in dilute acids; *metatitanic acids* are insol. dilute acids; by prolonged heating with conc. H_2SO_4 compounds are produced which dissolve on adding water. *Meta-acids* are also formed by heating *ortho- acids* to c. 100°. Experiments made by Merz (*J. pr.* 99, 166) show that the *meta- acids* lose water, on heating, more easily than the *ortho- acids*.

ORTHOTITANIC ACIDS. According to Wagner (*B.* 21, 960), a clear solution of an orthotitanic acid is obtained by adding water, a drop at a time, to $TiCl_4$, with constant shaking; HCl and $TiCl_4$ are given off (by the heat of the reaction), a solid is produced, then a greenish-yellow liquid, and finally a clear solution. By adding 1 pt. $TiCl_4$ to c. 6 to 7 pts. water, Thorpe (*C. J.* 47, 120) obtained an opalescent liquid which became clear after standing for 40 hours, and then contained orthotitanic acid; when this solution was heated ppn. of metatitanic acids began at c. 87°, and at c. 90° most of the Ti was ppd. A solution of $TiBr_4$ in water forms a perfectly clear liquid containing ortho-acid (T., *l.c.*, p. 126). The white flocculent solid obtained by adding $TiCl_4$ to dilute HClAq, ppg. by NH_3Aq when cold, washing with cold water, and drying in the air is $TiO_2.2H_2O$ ($= TiO_4H_4$), according to Merz (*J. pr.* 99, 166); **this composition is also assigned to the solid formed by keeping $TiCl_4.PCl_5$ under a bell-jar, with water and CaO, for some days, and then drying over H_2SO_4 (Tüttscheff, *A.* 141, 111). When TiO_4H_4 is dried *in vacuo* (Tüttscheff, *l.c.*), or over H_2SO_4**

(Merz, *l.c.*), the product is said to be $TiO_2.H_2O$ ($=H_2TiO_3 = TiO.O_2H_2$). The composition $2TiO_2.H_2O$ ($=H_2Ti_2O_5 = Ti_2O_3.O_2H_2$) is given to the product dried at 100° (Merz, *l.c.*; Demoly, *C. R.* 1849. 325), dried at 140° (Tüttscheff, *l.c.*), or dried *in vacuo* over H_2SO_4 (H. Rose, *A.* 52, 268); after drying at 100° or upwards, *meta-acids* are probably produced.

Orthotitanic acids are insoluble in water or alcohol; but dissolve easily in dilute acids; said also to dissolve in alkali carbonate solutions. The solutions in acids probably contain salts of the type TiX_4, $X = Cl, NO_3, \frac{1}{2}SO_4$, &c.; but compounds of the form $Ti(OH)_xX_y$, where X is a monovalent acidic radicle, and x is not greater than 3, may be formed, similar to the compounds $Ti(OH)_3Cl$, $Ti(OH)_2Cl_2$, and $Ti(OH)Cl_3$, obtained by O. v. d. Pfordten by the interaction of HClAq and $TiCl_4$ (*B.* 21, 1708; *v.* TITANIUM HYDROXYL CHLORIDES, p. 753). By adding a little conc. cold HClAq to orthotitanic acid, allowing to stand for some days, pouring off the clear liquid from undissolved acid, and evaporating *in vacuo*, Koenig a. O. v. d. P. (*B.* 22, 1485) obtained a white solid containing Ti and Cl in the ratio 1:1·47; they regarded this as consisting chiefly either of $TiCl_2(OH)_2$ but different in some properties from $TiCl_2(OH)_2$ obtained from $TiCl_4$—or chiefly of $TiCl(OH)_3.HCl$. White pps. are obtained by adding H_3PO_4Aq, H_3AsO_4Aq, or $H_2C_2O_4Aq$ to solutions of orthotitanic acids in dilute HClAq, HNO_3Aq, or H_2SO_4Aq, after making nearly neutral by NH_3Aq. When acid solutions of orthotitanic acids are diluted considerably and boiled for some time the whole of the Ti is ppd. as meta- acids. Ortho- acids are also partly changed to meta- acids by keeping under water for a long time (Wagner, *B.* 21, 960), or by washing with hot water. When an orthotitanic acid is heated strongly TiO_2 is produced, with vivid incandescence; the change from a meta- acid to TiO_2 is not accompanied by incandescence. According to Wagner (*l.c.*), the dehydration of moist ortho- acids by gently warming is accompanied by changes of colour from white to grey, green, and black.

METATITANIC ACIDS. Formed, as white powders, by dissolving ortho- acids in dilute acid and boiling for some time; also by fusing TiO_2 with $KHSO_4$ and boiling with much water; also by adding water to $TiCl_4$ or $TiBr_4$ and boiling; also by oxidising Ti by HNO_3 S.G. 1·25 (Weber, *P.* 120, 287). According to Weber (*l.c.*), freshly prepared dilute $TiCl_4Aq$ is not rendered turbid by HClAq, HNO_3Aq, or H_2SO_4Aq, but these acids at once ppt. metatitanic acids when added to dilute $TiCl_4Aq$ that has been boiled even for a few seconds. The pp. obtained by boiling a diluted solution of an orthotitanic acid in dilute H_2SO_4 is said to have the composition $TiO_2.2H_2O$ ($=TiO_4H_4$) when dried over H_2SO_4, the composition $3TiO_2.4H_2O$ ($=Ti_3O_{10}H_8 = Ti_3O_2.O_8H_8$) when dried at 120°, and the composition $3TiO_2.2H_2O$ ($=Ti_3O_8H_4 = Ti_3O_4.O_4H_4$) when dried at 140° (Tüttscheff, *A.* 141, 111); Merz (*J. pr.* 99, 166) gives the composition $TiO_2.H_2O$ ($=TiO_3H_2 = TiO.O_2H_2$) to the air-dried pp., and the composition $2TiO_2.H_2O$ ($=Ti_2O_5H_2 = Ti_2O_3.O_2H_2$) to the pp. dried over H_2SO_4, or at 60°.

Metatitanic acids are white powders, insoluble in water or dilute acids; after heating with conc. H_2SO_4 the products dissolve in water; when strongly *heated TiO_2 is formed without* incandescence.

COLLOIDAL TITANIC ACIDS. Graham (*T.* 1861. 213) obtained a gelatinous, probably orthotitanic, acid, insoluble in water, by dialysing a solution of $TiO_2.xH_2O$ in HClAq; by dissolving this gelatinous acid in such a quantity of cold dilute HClAq that not more than 1 p.c. titanic acid was present in the solution, and dialysing for several days, G. (*C. J.* 17, 325) obtained a dilute aqueous solution of colloidal titanic acid. Colloidal, insoluble, titanic acids have also been prepared by Knop (*A.* 123, 351), Rose (*G. A.* 73, 76 [1823]), and O. v. d. Pfordten (*B.* 17, 727).

TITANATES. These salts have not been thoroughly investigated. Those which have been best examined are either derivatives of H_2TiO_3 or H_4TiO_4, or are basic salts of the type $xMO.TiO_2$, where $x>1$. Some acid salts $MO.xTiO_2$, where $x>1$, are also known. The older investigations were made chiefly by H. Rose (*P.* 61, 507) and by Hautefeuille (*A. Ch.* [2] 4, 129).

Barium titanates. An *acid salt* $2BaO.3TiO_2$ ($=2BaTiO_3.TiO_2$ or $Ba_2TiO_4.2TiO_2$) was obtained by Bourgeois (*C. R.* 103, 141) in lustrous microscopic crystals, by heating to full redness a mixture of equivalent parts of TiO_2 and $BaCO_3$ with excess of $BaCl_2$, and washing with very dilute HClAq.

Calcium titanates. The *normal salt* $CaTiO_3$ occurs native as *perowskite*. The same salt was formed by heating to bright redness a mixture of equivalent parts of TiO_2 and $CaCO_3$ with excess of $CaCl_2$, and washing with very dilute HClAq (Bourgeois, *l.c.*).

Iron titanates. The mineral *titaniferous iron* or *ilmenite* is more or less pure $xFe_2O_3.yTiO_2$. By fusing a mixture of 2 pts. TiO_2 and 5 pts. FeF_2 with a large excess of NaCl, washing with water, and then with very dilute acid, Hautefeuille (*C. R.* 59, 733) obtained dark purple-violet, lustrous crystals of *ferrous titanate* Fe_2TiO_4 ($=2FeO.TiO_2$); but according to Koenig a. O. v. d. Pfordten (*B.* 22, 1485) the salt produced is *ferric titanate* $Fe_4(TiO_4)_3$ ($=2Fe_2O_3.3TiO_2$). K. a. O. v. d. P. say that the salt dissolves in water after warming with conc. H_2SO_4, forming a green solution containing $Fe_2(SO_4)_3$ and titanic acid.

Magnesium titanates. The *normal salt* $MgTiO_3$ ($=MgO.TiO_2$) was obtained (by Hautefeuille, *l.c.*) by heating to whiteness, for a short time in a closed crucible, a mixture of 1 pt. TiO_2 and 10 pts. $MgCl_2$ with a little NH_4Cl, washing with extremely dilute acetic acid, and then with water; lustrous, six-sided (probably trimetric) crystals, S.G. 3·91. The same salt is formed, according to Winkler (*B.* 23, 2657), by heating a mixture of TiO_2 and Mg powder. By heating a mixture of 2 pts. TiO_2, 1 pt. MgO, and 40 pts. $MgCl_2$, and washing with very dilute acetic acid, the salt Mg_2TiO_4 ($=2MgO.TiO_2$) is said to be formed in hard, lustrous, regular octahedra, S.G. 3·42 (H.).

Potassium titanates. When TiO_2 is fused with excess of K_2CO_3 the quantity of CO_2 given off corresponds with the formation of the *normal salt* K_2TiO_3; after fusion two layers are obtained, the lower of which is said to consist of K_2TiO_3, while the upper contains the undecomposed K_2CO_3. K_2TiO_3 is described as a yellowish, fibrous, easily fused solid (H. Rose, *P.* 61, 507). Water resolves it (according to Rose) into an insoluble *acid salt*, and a soluble *basic salt*; but according to Hermann (*J. pr.* 38, 92) no trace of titanic acid goes into solution in water, but all remains in the insoluble acid salt.

Sodium titanates. The *normal salt* Na_2TiO_3 was obtained by H. Rose (*l.c.*) similarly to the K salt; water resolves it into an insoluble *acid salt* and NaOHAq. By heating Na_2WO_4, and in some cases also WO_3, with mixtures of TiO_2 and Na_2CO_3 previously fused, Cormimbœuf (*C. R.* 115, 823) obtained three *acid salts*:
(1) $2Na_2O.3TiO_2$ ($=2Na_2TiO_3.TiO_2$, or $Na_4TiO_4.2TiO_2$), (2) $Na_2O.2TiO_2$($Na_2TiO_3.TiO_2$, or $Na_2Ti_2O_5$), (3) $Na_2O.3TiO_2$ ($=Na_2TiO_3.2TiO_2$, or $Na_2Ti_3O_7$).

Strontium titanates. An *acid salt* $2SrO.3TiO_2$ ($=2SrTiO_3.TiO_2$ or $Sr_2TiO_4.2TiO_2$) was obtained, in pale-greenish yellow cubes, S.G. 5·1, by Bourgeois (*C. R.* 103, 141), by heating equivalent parts of TiO_2 and $SrCO_3$ with excess of $SrCl_2$, and washing with very dilute HClAq.

Zinc titanates. The *normal salt* $ZnTiO_3$ was obtained by Lévy (*C. R.* 107, 421), by heating to redness a mixture of 2 pts. TiO_2, 8 pts. $ZnSO_4$, and 3 pts. K_2SO_4, and washing with dilute HClAq; pale-violet, silky needles, S.G. 3·17, scarcely acted on by boiling conc. acids or conc. KOHAq. By varying the proportion of TiO_2, $ZnSO_4$, and K_2SO_4 used, L. (*l.c.*) obtained the *normal salt* Zn_2TiO_4, which may also be regarded as a *basic salt* $ZnTiO_3.ZnO$; the *basic salt* $3ZnO.2TiO_2$ ($=2ZnTiO_3.ZnO$); and the *acid salt* $4ZnO.5TiO_2$ ($=4ZnTiO_3.TiO_2$).

FLUOTITANATES; *v. Titanifluorides*, under TITANIC FLUORIDE, *Combinations*, No. 2 (p. 742).

FLUOROXYTITANATES; *v. Titanoxyfluorides*, under TITANIC FLUORIDE (p. 742).

MOLYBDOTITANATES. A few compounds of the form $TiO_2.12MoO_3.2M_2O.x$aq, where $M=NH_4$ and K, are described by Péchard (*C. R.* 117, 788). By shaking with ether a solution of the NH_4 salt, acidified by HClAq, and allowing the ethereal liquid to evaporate, P. (*l.c.*) obtained *molybdotitanic acid* $TiO_2.12MoO_3.22$aq, in golden yellow octahedra, melting at c. 60°, very soluble in water.

OXALOTITANATES. By dissolving $TiO_2.xH_2O$ in hot KHC_2O_4Aq and cooling, Péchard (*C. R.* 116, 1513) obtained triclinic crystals of $2KHC_2O_4.TiO_2.H_2O$. By treating a solution of this salt with $BaCl_2$Aq, crystals of $Ba(HC_2O_4)_2.TiO_2.H_2O$ were obtained; and by decomposing this by an equivalent quantity of dilute H_2SO_4Aq, filtering, and evaporating *in vacuo*, long needles of *oxalotitanic acid* $2H_2C_2O_4.TiO_2.2H_2O$ were obtained.

SILICOTITANATES; *v.* this heading, p. 464.

Titanium, oxychlorides of. Several oxychlorides are known. (1) $TiOCl_2$. According to Demarçay (*C. R.* 104, 111), this is the first product of heating TiO_2 and CCl_4 in a sealed tube; it is described as a yellow crystalline solid. Heated with CCl_4 it gives $TiCl_4$ and $COCl_2$. (2) TiOCl. Obtained by passing a mixture of $TiCl_4$ vapour and dry H over TiO_2 in a tube heated white hot; Ti_2O_3 and Ti_2Cl_6 are also produced in the reaction (Friedel a. Guérin, *Bl.* [2] 22, 481). Brown, orthorhombic leaflets; heated in air burns to TiO_2 and $TiCl_4$. (3) $Ti_4O_2Cl_8$. Formed by passing $TiCl_4$ vapour through a red-hot tube containing fragments of porcelain (Troost a. Hautefeuille, *C. R.* 73, 563). (4) By allowing $TiCl_4$ to deliquesce in air, and then evaporating over H_2SO_4 and CaO, Merz (*Bl.* [2] 7, 401) obtained a solid approximating in composition to $Ti_4O_6Cl_4.16H_2O$. In connection with oxychlorides *cf.* TITANIUM HYDROXYL CHLORIDES (p. 743).

Titanium, oxyfluoride of. By decomposing by water the crystals formed by dissolving $TiO_2.xH_2O$ in HFAq and evaporating, Berzelius (*P.* 4, 1) obtained a white solid, of which he said it was an insoluble, 'so to say, *basic*,' compound.

The *titanoxyfluorides* $TiO_2F_2.2MF$ may be regarded as compounds of the oxyfluoride TiO_2F_2 (*v.* TITANIC FLUORIDE, p. 742).

Titanium, oxythiochloride of. The compound $TiCl_3.OSO_2.Cl$ formed by the reaction of $TiCl_4$ with $SO_2.OH.Cl$ may be regarded as TiO_3SCl_4 (*v.* TITANIC CHLORIDE, *Reactions*, No. 10, p. 740).

Titanium, salts of. Not many salts have been prepared by replacing H of oxyacids by Ti; most of those that have been isolated are basic salts derived from the oxide TiO_2. One salt, $Ti_2(SO_4)_3$, corresponding with the oxide Ti_2O_3 has been isolated. For the individual salts *v.* NITRATES, vol. iii. p. 517; PHOSPHATES, this vol. p. 112, TiP_2O_7, prepared by dissolving $TiO_2.xH_2O$ in molten H_3PO_4 (Hautefeuille a. Margottet, *C. R.* 102, 1017) should be added; and SULPHATES, this vol. p. 580.

Titanium, sulphides of. Three compounds of Ti and S have been isolated: TiS_2, Ti_2S_3, and TiS, corresponding with the three oxides TiO_2, Ti_2O_3, and TiO.

TITANIUM DISULPHIDE TiS_2. (*Titanic sulphide.*) Mol. w. unknown. H. Rose (*P.* 8, 177) said that this compound was obtained by passing vapour of CS_2 over very strongly heated TiO_2; but O. v. d. Pfordten (*B.* 17, 727) and Thorpe (*C. J.* 47, 491) have found that it is not possible by this method to obtain TiS_2 free from Ti oxides. TiS_2 is prepared by passing perfectly dry H_2S into $TiCl_4$ kept somewhat below its b.p., and sending the mixed vapours through a glass tube heated to incipient redness; TiS_2 deposits in the tube, and HCl is given off (Ebelmen, *A. Ch.* [3] 20, 285; confirmed by O. v. d. Pfordten, *B.* 17, 727). According to O. v. d. P. (*A.* 234, 257), the H_2S should be passed through $CrCl_2$Aq, to remove traces of O, and dried by means of P_2O_5; and the tube should be filled with H_2S before the mixed vapours are passed into it.

TiS_2 forms large, brass-yellow, lustrous, metal-like scales.

TiS_2 is decomposed to Ti_2S_3 and S by heating in *hydrogen* or *nitrogen*; it is not changed by heating in *hydrogen in presence of excess of hydrogen sulphide*; heated to redness in *carbon dioxide* it is completely oxidised to TiO_2 (O. v. d. P., *A.* 234, 257). Ebelmen (*l.c.*) gives the following reactions: with dry *chlorine* gives $TiCl_4$ and S_2Cl_2; *heated in air*, TiS_2 is burnt to

TiO_2 and SO_2; exposure to *moist air* decomposes **TiS_2 gradually, with evolution of H_2S;** heated to redness with *steam* gives $TiO_2.xH_2O$, H_2S, and H; *nitric acid* produces $TiO_2.xH_2O$, S, and NO; *aqua regia* oxidises it to $TiO_2.xH_2O$ and H_2SO_4Aq; not acted on by *hydrochloric acid* (H. Rose said that TiS_2 dissolved slowly in HClAq, giving off H_2S); insoluble in *potassium sulphide* solution; digestion with *potash solution* produces K titanate and KHSAq (Rose).

Titanium sesquisulphide Ti_2S_3. Mol. w. unknown. Thorpe (*C. J.* 47, 491) obtained this compound by passing the vapours of moist H_2S and CS_2 over powdered TiO_2 heated to very bright redness in a porcelain tube; dry H_2S and CS_2 had no action on TiO_2. T. describes Ti_2S_3 as a greenish-black powder; he did not obtain it quite free from TiS_2, as by heating at a lower temperature than full redness in H_2S and CS_2 it is slowly changed to TiS_2. O. v. d. Pfordten (*A.* 234, 257) obtained Ti_2S_3 by heating TiS_2 to full redness in dry H or N (S being set free); he describes it as a grey, metal-like solid; insoluble in NaOHAq; soluble in HNO_3Aq or conc. H_2SO_4 forming green solutions.

Titanium monosulphide TiS. Mol. w. unknown. Formed by very strongly heating TiS_2 in perfectly dry H quite free from O (T., *l.c.*; O. v. d. P., *l.c.*). A black powder (T., *l.c.*); forms dark-red crystals (O. v. d. P., *l.c.*). Slowly acted on by HNO_3Aq or *aqua regia*; insoluble in NaOHAq.

Titanium, sulphochloride of, *v.* Titanium thiochloride, *infra*.

Titanium, thiochloride of. The pp. formed by passing pure dry H_2S into hot $TiCl_4$ is probably a thiochloride, according to O. v. d. Pfordten (*A.* 234, 257). M. M. P. M.

TITANIUM GROUP OF ELEMENTS. The four elements, *titanium*, *zirconium*, *cerium*, and *thorium* form, with *carbon*, the *even-series* family of Group IV. in the periodic classification of the elements. There is yet an element to be discovered between Ce and Th; this unknown element will come in series 10 of Group IV. The titanium family of elements is closely allied to the tin family—Ge, Sn, Pb—which, with Si, form the odd-series members of Group IV. Carbon is the first even-series member, and silicon the first odd-series member, of the group; these two elements are more like one another than they are like the rest of the group.

For the properties and relations of C and Si *v.* Carbon group of elements, vol. i. p. 682; and for the tin family *v.* Tin group of elements, this vol. p. 735.

The presence of an element, before unknown, in a Cornish mineral was recognised by Gregor in 1791, and by Klaproth a few years later; the element—called titanium by Klaproth—was isolated by Berzelius in 1824. Klaproth, in 1789, recognised the presence of a new earth in *zirconite* from Ceylon; the metal zirconium was isolated by Berzelius in 1824. In 1803 the presence of a new earth in a Swedish mineral was announced by Klaproth, who gave the name of cerium to the metal of the earth he had discovered; Mosander isolated the element in 1826. Berzelius discovered a new earth, in a Norwegian mineral, in 1828, and isolated the metal of the earth, which he called thorium, in the same year.

None of the four elements Ti, Zr, Ce, or Th occurs native; the compounds of these elements are comparatively rare, especially those of Ce and Th.

The most frequently found compounds are the oxides MO_2, generally in combination with SiO_2 and with alkaline earths. The metals are obtained by reducing their double fluorides by Al, K, or Na; also in some cases by reducing the chlorides by K or Na; Ce has also been isolated by electrolysing molten $CeCl_3$. The table on the following page presents some of the physical and chemical properties of the elements.

General formulæ and characters of compounds.—Oxides.—MO_3, probably for all (? Th_2O_7); MO_2, for all; M_2O_3, when M = Ti or Ce; perhaps TiO. Hydrates of MO_2 exist.

Sulphides.—MS_2, when M = Ti or Th, ? Zr; M_2S_3, when M = Ti or Ce; TiS.

Haloid compounds.—MX_4, when X = Br, Cl, F or I (only CeF_4 prepared); MX_3, when M = Ti, and X = Cl, also when M = Ce and X = Br, Cl, F or I; $TiCl_2$. Salts.—MR_4, R = NO_3, $\frac{1}{2}SO_4$, $\frac{1}{3}PO_4$, &c.; most are basic when M = Ti or Zr, but when M = Ce many are normal, and when M = Th most are normal; several salts Ce_2R_6 are known, and a few Ti_2R_6; the Ce_2R_6 salts are more stable than the CeR_4 salts. Salts containing M in the acidic radicle.—M_2TiO_3 and others of general form $xMO.yTiO_2$; M_2ZrO_3, M_4ZrO_4, and others of general form $xMO.yZrO_2$. No cerates or thorates isolated. Salts X_2MF_6 known when M = Ti, Zr, or Th; $3CeF_4.3KF$ known. Acids. H_2TiO_3, $H_2Ti_2O_5$, H_4TiO_4, H_2TiF_6; various hydrates $ZrO_2.yH_2O$ act as feeble acids; H_4ThO_4 and $H_2Th_4O_9$ are perhaps feeble acids, but it is said that ThO_2 does not decompose alkali carbonates when fused therewith.

The *oxides* MO_2 are basic, and also feebly acidic when M is Ti or Zr; they interact with some acids to form corresponding salts, and, when M = Ti or Zr, with alkalis to form salts wherein M forms part of the acidic radicle; no salts of oxyacids with Ce or Th in the negative radicles have yet been isolated. Several hydrates of MO_2 exist, they easily pass one into the other with small changes of temperature; some of these hydrates react as feeble acids towards strong bases, forming salts of the types X'_2MO_3, X'_4MO_4, and, generally, $xX'_2O.yMO_2$; these salts are not referable to such definite forms as the stannates or silicates are, but they resemble these classes of salts fairly closely.

The *salts* which are derived from the oxides MO_2, by the interactions of these oxides with acids, are of the form MX_4, where X = NO_3, $\frac{1}{2}SO_4$, $\frac{1}{3}PO_4$, &c.; when M = Ti most of the salts that are known are basic; when M = Zr, many are basic, but a fair number of normal salts is also known; when M = Ce or Th, most of the salts that have been isolated are normal. Little is known of the oxides MO_3; as they are obtained by adding H_2O_2Aq and an alkali to solutions of salts MX_4, they are probably superoxides; the formula Th_2O_7 that is assigned to the oxide of Th formed in this way cannot be accepted as final. The oxides Ti_2O_3 and Ce_2O_3 are basic; the most definite and stable salts of

—	TITANIUM.	ZIRCONIUM.	CERIUM.	THORIUM.
Atomic weights.	48	90	139·9	232
	Molecular weights unknown. Mol. weights of one or more compounds of each element, except Ce, have been determined by Avogadro's law; spec. heats determined directly.			
Melting-points.	Has not been fused	c. 1200°	c. 800°	Has not been fused
Spec. gravities (approx.)	3·6	4·2	6·7	11·0
Spec. heats.	·13	·066	·0448	·0276
$\frac{\textit{Atomic weight.}}{\textit{Spec. gravities}\text{ (approx.)}}$	13·4	21·4	21·1	21·1
Physical properties.	Obtained only as a powder; black, lustrous, apparently amorphous. The powder has not been fused.	A black amorphous powder; resembling lampblack, but much heavier. Also obtained as a very lustrous, hard, brittle solid, resembling Sb. Said to melt above m.p. of Si.	Steel-grey, very lustrous metal; malleable, and ductile. Melts much more easily than any other member of the family.	Dark-grey, lustrous powder; also obtained in microscopic octahedral crystals. Has not been fused.
Occurrence and Preparation.	The four metals occur chiefly as silicates, Ti and Zr in moderate quantities and the others only in a few rare minerals. The metals are prepared by reducing the chlorides, or alkali salts of the form K_2(or Na_2)MF_6, by heating with K or Na; Ce also prepared by electrolysing molten $CeCl_3$.			
Chemical properties.	Burns brilliantly when heated in air, or in O, forming TiO_2. Decomposes H_2O at 100°, giving off H. Combines readily with Cl, less readily with Br, and with I only when vapour of I is passed over heated Ti. Dissolves in warm dilute HClAq, H_2SO_4Aq, HNO_3Aq, or HFAq. Forms two classes of salts TiX_2 and TiX_4, $X = NO_3$, $\frac{1}{2}SO_4$, &c.; very few TiX_2 salts isolated, and not many TiX_4; all salts easily decomposed. Salts derived from the acidic hydrates $xTiO_2.yH_2O$ also known. The acids H_2TiF_6 and $H_2TiO_2F_4$, and salts derived therefrom, are known. TiO_3, probably a superoxide, exists. Combines fairly readily with N, and with N and C. Atom of Ti is tetravalent in gaseous molecules $TiCl_4$ and TiI_4.	Amorphous Zr burns brilliantly when heated in air, or O, forming ZrO_2; the crystalline metal is superficially oxidised at a white heat; it burns in O-H flame. Combines with Cl, probably also with Br and I; compounds ZrX_4 are formed by heating ZrO_2 and C in X. Combines directly with S. Dissolves slowly in hot H_2SO_4, HClAq, HNO_3Aq; rapidly in HFAq. Decomposes molten KOH; crystalline Zr is said not to be oxidised by molten KNO_3 or $KClO_4$. Forms salts ZrX_4, $X = NO_3$, $\frac{1}{2}SO_4$, &c.; most salts isolated are basic, $xZrO_2.yR$. Salts derived from acid H_2ZrF_6 are known. Also forms zirconates $yMO.zZrO_2$ where Zr enters into negative radicle of salts. Oxide higher than ZrO_2, probably ZrO_3, (? superoxide) exists. ZrH_2 perhaps exists. Atom of Zr is tetravalent in gaseous molecule $ZrCl_4$.	Burns when heated in air, or O, to CeO_2. Decomposes cold water, giving off H. Combines directly with Cl, Br, I vapour, S vapour, and P vapour. Dissolves easily in HClAq, HNO_3Aq, H_2SO_4Aq, or HFAq. Forms two classes of salts, Ce_2X_6 and CeX_4, $X = NO_3$, $\frac{1}{2}SO_4$, &c.; salts Ce_2X_6 are more stable than CeX_4, the latter are easily reduced to Ce_2X_6. No cerates, where Ce forms part of negative radicle, have been isolated. Salts of form M_2CeF_6 not isolated. CeO_3, probably a superoxide, seems to exist.	Burns, when heated in air or O below redness, to ThO_2. Combines with Cl, Br, or I when heated; also with S vapour when heated therein. Easily dissolved by HClAq or HFAq; slowly by hot H_2SO_4Aq; HNO_3Aq has only a slight action. Forms salts ThX_4, $X = NO_3$, $\frac{1}{2}SO_4$, &c.; fair number of basic salts known. Hydrates of ThO_2, $ThO_2.2H_2O$ and $4ThO_2.H_2O$, are probably weak acids, but thorates have not been isolated. Oxide higher than ThO_2, probably Th_2O_7, isolated (? superoxide). ThH_2 perhaps exists. Atom of Th is tetravalent in gaseous molecule $ThCl_4$.

Ce are derived from this oxide. Several of the *haloid compounds* MX_4 have been gasified without decomposition, viz. $TiCl_4$, TiI_4, $ZrCl_4$, and $ThCl_4$. The haloid compounds MX_4 form many double compounds with other halides; some of these are certainly best regarded as salts of hypothetical acids containing M and X in their acidic radicles; the salts of this class R_2MF_6 are characteristic of the elements of Group IV.; all the elements of the group, except C and Ce, give these salts R_2MF_6, Ce is said to form $K_3Ce_2F_{11}(=2CeF_4.3KF)$, but further examination will most probably lead to the isolation of salts R_2CeF_6. Ti and Ce form chlorides MX_3, or more probably M_2X_6 from the analogy of C_2Cl_6 and Si_2Cl_6; Ce also forms Ce_2Br_6, Ce_2F_6, and Ce_2I_6, indeed the only haloid compound of Ce belonging to the form MX_4 that has yet been isolated is CeF_4. The *sulphides* have not been thoroughly examined; Ti is the only member of Group IV. which is known to form three sulphides corresponding with the oxides, TiS, Ti_2S_3, and TiS_2; one sulphide of Zr is known, probably ZrS_2; ThS_2 is the only sulphide of Th that has been isolated; and the only known sulphide of Ce is Ce_2S_3. So far as investigation has gone, the sulphides of Ti, Zr, Ce, and Th are basic.

A comparison of the titanium family with the tin family, which comprises the odd-series members of Group IV. (C and Si being omitted), shows that Ti, Zr, Ce, and Th are more metallic, on the whole, than Ge, Sn, and Pb. Th is certainly the most markedly positive element of Group IV., and Ti is at least not more negative than Ge; Zr is more metallic than Ge, and Ce more metallic than tin. The following formulæ show that, so far as composition goes, there is about an equal similarity between C and Si and the Ti elements, as between C and Si and the tin elements:

Oxides				*Sulphides*			*Chlorides, &c.*

SnO	? Sn_2O_3	SnO_2		SnS	? ? Sn_2S_3	SnS_2	$SnCl_2$		$SnCl_4$
PbO	Pb_2O_3	PbO_2		PbS		? PbS_2	$PbCl_2$		$PbCl_4$ (?)

A comparison of the odd-series families of the different groups with the even-series families (omitting series 2 and 3) shows that, speaking broadly, the members of the even-series families are more metallic in their chemical properties than the members of the odd-series families, and that the general difference between even and odd families becomes more marked in the higher than in the lower groups (*v.* Table in vol. iii. p. 811). For instance, the even family of Group VI.—Cr, Mo, W, and U—is decidedly more metallic than the odd family of the same group—S, Se, and Te; but although the even family of Group II.—Ca, Sr and Ba—is more metallic than the odd family of the same group—Mg, Zn, Cd and Hg—there is not nearly so great a difference between these two families as there is between the two families of Group VI. Considering that the titanium and the tin elements belong to even and odd series, respectively, of Group IV., which group comes midway in the general periodic scheme of classification, we should expect the titanium (even-series) family to be rather more metallic than the tin (odd-series) family, but at the same time we should expect these two families to be very like one another; this is exactly what a study of the two families shows to be the case.

In connection with this article *v.* TIN GROUP OF ELEMENTS, this vol. p. 735, and CARBON GROUP OF ELEMENTS, vol. i. p. 682).

M. M. P. M.

TITANOFLUORHYDRIC ACID H_2TiF_6 *v.* *Titanifluorhydric acid*, under TITANIC FLUORIDE, *Combinations*, No. 1, p. 742.

TITANOFLUORIDES M_2TiF_6 *v.* *Titanifluorides*, under TITANIC FLUORIDE, *Combinations*, No. 2, p. 742.

TITANOXYFLUORHYDRIC ACID $H_2TiO_2F_4$ *v.* TITANIC FLUORIDE, p. 742.

TITANOXYFLUORIDES $M_2TiO_2F_4$ *v.* TITANIC FLUORIDE, p. 742.

TOLALLYL SULPHIDE C[illegible]H[illegible]S_2. [174°]. (350°–360° i.V.). A product of distillation of benzyl sulphide (Märcker, *A.* 136, 75; Forst, *A.* 178, 370; Baumann a. Klett, *B.* 24, 3313). Plates (from ether).

TOLANE *v.* DI-PHENYL-ACETYLENE.

Tolane dibromide *v.* DI-BROMO-PHENYL-ETHYLENE.

Tolane chlorides *v.* CHLORO-PHENYL-ETHANE and CHLORO-PHENYL-ETHYLENE.

TOLENE *v.* TOLU BALSAM.

p-**TOLENYL-AMIDINE** $C_8H_{10}N_2$ *i.e.* $C_6H_4Me.C(NH)(NH_2)$. [102°]. Formed by the action of alcoholic NH_3 on the hydrochloride of *p*-tolenyl-imido-ethyl-ether (Glock, *B.* 21, 2653). Pearly plates, sol. alcohol and ether.

Reactions.—1. $CO.Cl_2$ in toluene and NaOH give $(C_6H_7.C(NH).NH)_2CO$ and $C_7H_7.C\begin{matrix}\diagup N.C(C_7H_7)\diagdown\\ \diagdown N:C(OH)\diagup\end{matrix}N$ [over 300°] (Pinner, *B.* 25, 1425).—2. *Oxalacetic ether* and NaOH form $C_7H_7.C(NH).NH.CO.CH_2.CO.CO_2Et$ [190°] and $C_7H_7.C\begin{matrix}\diagup N.C(CO_2H)\diagdown\\ \diagdown N:C(OH)\diagup\end{matrix}CH$ [252°] (Pinner, *B.* 25, 1422).

Salts.—$B'HCl\frac{1}{2}aq.$ [218°].—$B'_2H_2PtCl_6$ [225°].—$B'HNO_2$. [133°]. Needles, v. sol. water (Kirschnick, *A.* 265, 187).—$B'HNO_3 2aq.$ [95°].—$B'_2H_2SO_4 2aq.$ [240°], v. sol. water.

o-**TOLENYL-AMIDOXIM** $C_8H_{10}N_2O$ *i.e.* $C_7H_7.C(NOH).NH_2$. [149·5°]. Formed by heating *o*-toluic nitrile with hydroxylamine hydrochloride, alcohol, and Na_2CO_3 (Schubart, *B.* 22, 2438). Needles (from hot water), v. sol. alcohol and ether.

Ethyl ether $C_7H_7.C(NOEt).NH_2$. [140°]. Prisms, v. sol. alcohol.

Benzoyl derivative $C_7H_7.C(NOBz).NH_2$. [145°]. Needles, sol. alcohol. Conc. H_2SO_4 forms $C_7H_7.C{<}\substack{N.O\\N}{>}CPh$ [80°].

o-Toluyl derivative $C_7H_7.C(NO.CO.C_7H_7).NH_2$. [168°]. Converted at 180° into $C_7H_7.C{<}\substack{N.O\\N}{>}C.C_7H_7$ [59°] (Stieglitz, *B.* 22, 3156). Sodium diazobenzene sulphonate forms $C_7H_7.C{<}\substack{N.O\\NH}{>}C(NH_2).C_7H_7$ [110°].

p-**Tolenyl-amidoxim** $C_8H_{10}N_2O$ *i.e.* $C_6H_4Me.C(NOH).NH_2$. *Toluamidoxim.* [146°]. Formed by combination of toluic nitrile with hydroxylamine (Schubart, *B.* 19, 1487). White plates, sol. alcohol, ether and hot water. Yields NaA′, a hygroscopic mass, and HA′HCl [187°], crystallising in prisms.

Reactions.—1. *Benzene sulphonic chloride* forms $C_7H_7.C{<}\substack{N.O\\N}{>}SO.C_6H_5$ [89°] (Pinner, *B.* 24, 4173).—2. *Aceto-acetic ether* gives rise to $C_7H_7.C{<}\substack{N.O\\N}{>}C.CH_2Ac$ [97°] (Schubart, *B.* 22, 2438).—3. *Acetic aldehyde* forms the compound $C_7H_7.C{<}\substack{N.O\\NH}{>}CHMe$ [127·5°].—4. Hot HOAc forms $C_7H_7.C{<}\substack{N.O\\N}{>}C.C_7H_7$ [135°].—5. $COCl_2$ produces $C_7H_7.C{<}\substack{N.O\\NH}{>}CO$ [220°].—6. $ClCO_2Et$ yields $C_7H_7.C(NH_2){:}NO.CO_2Et$ [130°].—7. *Phenyl cyanate* gives $C_7H_7.C(NOH).NH.CO.NHPh$ [155°].—8. *Phenyl thio-carbimide* reacts forming $C_7H_7.C(NOH).NH.CS.NHPh$.—9. *Potassium cyanate* acting on the hydrocloride gives rise to $C_7H_7.C(NOH).NH.CO.NH_2$ [170°].—10. Ac_2O and NaOAc acting on the hydrochloride form $NH(C(NH).C_7H_7)_2$ [153°] (Glock, *B.* 21, 2657).—11. *Succinic anhydride* forms the compound $C_7H_7.C{<}\substack{N.O\\N}{>}C.CH_2.CH_2.CO_2H$ [138·5°].—12. Boiling Ac_2O forms $C_7H_7.C{<}\substack{N.O\\N}{>}CMe$ [80°]. 13. CS_2 and alcohol form, on long boiling, $C_7H_7.C(NSH)NH.CS.SHH_2N.C(NSH).C_7H_7$ (Crayen, *B.* 24, 390).—14. CS_2 and alcoholic potash yield $C_7H_7.C{<}\substack{N.S\\NH}{>}CS$ [165°].

Methyl ether $C_7H_7.C(NOMe).NH_2$. [85°].

Ethyl ether EtA′. [64°]. Needles. Converted by HBr and $NaNO_2$ into $C_7H_7.CBr{:}NOEt$, an oil, decomposed at 155° (Schubart, *B.* 22, 2434), while hydrogen chloride and $NaNO_2$ form $C_7H_7.CCl{:}NOEt$ (200°).

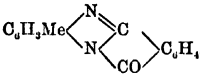
Benzoyl derivative $C_7H_7.C(NOBz).NH_2$. [178°]. Converted by heat into $C_7H_7.C{<}\substack{N.O\\N}{>}CPh$.

References.—Nitro- and Oxy-toluamidoxim.

p-**TOLENYL-IMIDO-ETHYL ETHER** $C_7H_7.C(NH).OEt$. The hydrochloride B′HCl [161°] formed by the action of dry HCl on *p*-toluic nitrile dissolved in ether-alcohol forms prisms, yielding $B'_2H_2PtCl_6\,2aq$, converted at 200° into *p*-toluic amide, by NH_3 into *p*-tolenyl-amidine, by aniline into di-phenyl-tolenyl-amidine [168°], and by Ac_2O into the compound $C_6H_4Me.C(NH).OAc$ [147°] (Glock, *B.* 21, 2650). The free base is liquid and changes on keeping into a polymeride [260°].

TOLENYL-PHENYLENE-DIAMINE $C_6H_4{<}\substack{NH\\N}{>}C.C_7H_7$. [268°]. Formed by reduction of tolyl-*o*-nitro-aniline and also from *p*-toluyl chloride and *o*-phenylene-diamine in benzene (Hübner a. Hanemann, *A.* 210, 328). Prisms, sl. sol. water, sol. alcohol.

TOLENYL-PHTHALAMIDONE $C_{15}H_{10}N_2O$ *i.e.*



[188°]. Got from tolenyl-benzenyl-amidine *o*-carboxylic acid (Bistrzycki, *B.* 25, 1984).

TOLENYL-XYLYLENE-DIAMINE $C_{15}H_{16}N$ *i.e.* [1:4] $C_6H_4Me{<}\substack{N\\NH}{>}C_6H_2Me_2$ $\left[\substack{5\\6}:1:3\right]$ [217°]. Formed by reducing the *p*-toluyl derivative of nitro-xylidine (Brückner, *A.* 205, 125; Hübner, *A.* 210, 333). Long crystals (from dilute alcohol).—B′HCl.—$B'HNO_3$.—$B'_2H_2SO_4$.

TOLIDINE *v.* Di-amido-ditolyl.

TOLIL *v.* Di-tolyl-diketone.

TOLIL-BENZOÏN *v.* Benzoïn, *Reaction* 9.

TOLINDOLE *v.* Methyl-indole.

TOLISATIN *v.* *Methyl*-isatin.

TOLU-ACET-ALDEHYDINE $C_{11}H_{14}N_2$ *i.e.* $C_7H_6(N{:}CHMe)_2$ or $C_7H_6{<}\substack{N\\NEt}{>}CMe$ (?) [91° uncor.]. Formed together with a small quantity of ethenyl-tolylene-diamine, by mixing tolylene *o*-diamine (1 mol.) with aldehyde (2 mols.) in cold HOAc (Hinsberg, *B.* 20, 1588).

TOLU-AMIDOXIM *v.* Tolenyl-amidoxim.

TOLU BALSAM. Obtained from incisions in the stem of *Myroxylum toluiferum* growing in Columbia, South America. It contains a terpene, tolene $C_{10}H_{16}$ (154°–170°), benzoic and cinnamic acids, benzyl cinnamate and two resins: $C_{18}H_{18}O_4$ [60°] v. sol. alcohol and ether and $C_{18}H_{20}O_5$ [above 100°], insol. alcohol and ether (Deville, *A.* 44, 304; Scharling, *A.* 97, 71; E. Kopp, *A.* 64, 372; Busse, *B.* 9, 830; Baillon, *Ph.* [3] 4, 385).

TOLUBENZYLAMINE *v.* Methyl-benzyl-amine.

TOLUENE C_7H_8 *i.e.* $C_6H_5.CH_3$. *Methyl-benzene. Retinaphtha. Phenyl-methane.* Mol. w. 92. V.D. 3·20 (calc. 3·29). (109°) (R. Schiff, *A.* 220, 91); (111°) (Wilbrand a. Beilstein, *A.* 128, 259; Tollens a. Fittig, *A.* 131, 304). S.G. $\frac{20}{4}$ ·8656 (Brühl); ^{24} ·8566 (Gladstone, *C. J.* 59, 290); $\frac{13}{4}$ ·8708 (S.). C.E. (13°–109°) ·001242. S.V. 118 (S.). μ_D = 1·4893 (G.). μ_β = 1·507 (B.). R_∞ = 50·06. H.F.p. −3520. H.F.v. −5260 (Thomsen, *Th.*). H.C. 933,762 (Stohmann, *J. pr.* [2] 35, 41). *Critical temperature* 321° (Pawlewski, *B.* 16, 2634). Occurs in coal tar (Mansfield). Obtained by dry distillation from balsam of tolu (Deville, *A. Ch.* [3] 3, 168; Muspratt a. Hofmann, *A.* 54, 9), from dragon's blood (Glénard a. Boudault, *C. R.* 19, 505), from the resin of *Pinus maritima* (Pelletier a. Walter, *A. Ch.* [2] 67, 278), and from wood (Völckel, *A.* 86, 334).

Formation.—1. By distilling vulpic acid with KOH (Möller a. Strecker, *A.* 113, 69).—2. By the action of sodium on a mixture of bromobenzene and MeI (Fittig a. Tollens, *A.* 131, 303).—3. By passing petroleum vapour over red-hot charcoal (Letny, *B.* 11, 1210).—4. By heating petroleum with $AlCl_3$ in presence of PbO and air (Friedel a. Crafts, *Z.* 1878, 1166).—5. By passing MeCl or CH_2Cl_2 into benzene containing $AlCl_3$ (Friedel a. Crafts, *A. Ch.* [6] 1, 460; 11, 264).—6. Together with CH_4 by heating benzene with MeI and I (Rayman a. Preis, *A.* 223, 317).—7. By distilling cresol with P_2S_5 (Geuther, *A.* 221, 58).—8. By distilling toluic acid with baryta (Noad, *A.* 63, 305).

Properties.—Oil, smelling like benzene.

Reactions.—1. When passed through a *red-hot tube* it yields benzene, styrene, naphthalene, diphenyl, anthracene, phenanthrene, and other products (Ferko, *B.* 20, 661; *cf.* Berthelot, *Bl.* 7, 218; Graebe, *B.* 7, 48).—2. Distillation over red-hot PbO gives benzene, di-phenyl-ethylene, diphenyl, phenanthrene, and anthracene (Lorenz, *B.* 7, 1097; Vincent, *C. R.* 100, 908).—3. By *electrolysis* of toluene to which alcohol and H_2SO_4 have been added benzoic aldehyde and phenose are formed (Rénard, *C. R.* 92, 965).—4.—When electric sparks are passed through toluene, acetylene and hydrogen are given off (Destrem, *Bl.* [2] 42, 267).—5. $AlCl_3$ at 200° in sealed tubes forms benzene, and *m*- and *p*-xylene (Friedel a. Crafts, *C. R.* 100, 692; Anschütz, *A.* 235, 178).—6. *Oxygen* passed through toluene containing $AlCl_3$ forms cresol (Friedel a. Crafts, *C. R.* 86, 884).—7. A mixture of toluene and ethylene passed through a red-hot tube yields benzene, styrene, and anthracene (Ferko).—8. CH_2Cl_2 and $AlCl_3$ yield di-tolyl-methane (280°-290°), di-methyl-anthracene [232°], and *m*-, and *p*-xylenes (Friedel a. Crafts, *Bl.* [2] 41, 322).—9. *Bromine* acts upon toluene in the dark as readily as in diffused daylight, with production of *o*- and *p*-bromo-toluene. The addition of iodine greatly hastens the reaction, but the same products are formed. In direct sunlight the substitution takes place entirely in the side-chain, with production of benzyl bromide. But if iodine (even 2 p.c.) is present the effect of the sunshine is entirely counteracted, and the substitution takes place wholly in the nucleus (Schramm, *B.* 18, 606; *cf.* Zakrzewski, *M.* 8, 304).—10. *Chlorine*, in presence of I, acting even on boiling toluene, forms chloro-toluene and benzyl chloride (Beilstein a. Geitner, *A.* 231, 170; *cf.* Aronheim, *B.* 8, 1401).—11. CrO_2Cl_2 added slowly to a solution of toluene in CS_2 ppts. $C_7H_8 2CrO_2Cl_2$, which slowly absorbs moisture, being converted into benzoic aldehyde (Étard, *A. Ch.* [5] 22, 223).—12. H_2SO_4 yields the *o*- and *p*-sulphonic acids, converted by potash-fusion into *o*- and *p*-cresol (Wurtz, *A. Ch.* [4] 25, 108).—13. Bz_2O_2 forms $C_{14}H_{12}$ (c. 260°) isomeric with the di-phenyl-ethylenes, and yielding benzoic acid on oxidation (Lippmann, *M.* 7, 521).—14. HNO_3 forms *o*- and *p*-nitro-toluene.—15. *Paraldehyde* and conc. H_2SO_4 form ditolylethane and $C_{23}H_{24}$ (350°-360°) (O. Fischer, *B.* 7, 1194).

Compounds $(C_7H_8)_3AlCl_6$. S.G. ^{2} 1·08 (Gustavson, *B.* 11, 2151). Oil.—$(C_7H_8)_3AlBr_3$. S.G. 1·37.

Dihydride C_7H_{10}. (105°-108°). Formed by heating toluene with PH_4I at 350° (Baeyer, *A.* 155, 271; *Z.* [2] 4, 445).

Tetrahydride C_7H_{12}. (104°). S.G. ^{15} ·797. Occurs in the product of distillation of colophony (Rénard, *A. Ch.* [6] 1, 231). Oil, sol. alcohol and ether. Rapidly absorbs oxygen. In contact with water it forms crystalline $C_7H_{16}O_2$. H_2SO_4 forms two polymerides (230°-235°), one only being oxidisable by air.

Hexahydride C_7H_{14}. (97°). S.G. $\frac{0}{0}$ ·7741. C.E. (0°-20°) ·00119. S.V. 142 (Lossen, *A.* 225, 109). H.C. 1,092,800 (Longuinine, *C. R.* 93, 275). Formed by heating toluene with conc. HIAq at 280° (Wreden, *A.* 187, 161; *cf.* Berthelot, *Bl.* [2] 7, 124; 26, 146). Occurs in oil of resin. Completely oxidised by a hot mixture of HNO_3 and H_2SO_4.

References.—TRI-AMIDO-, BROMO-, BROMO-IODO-, BROMO-IODO-NITRO-, BROMO-NITRO-, CHLORO-, CHLORO-IODO-, CHLORO-NITRO-, IODO-, IODO-NITRO-, NITROSO-, NITRO-, and OXY- TOLUENE.

TOLUENE ARSONIC ACID *v.* ARSENIC.

TOLUENE-AZIMIDO-TOLUENE *v.* AZIMIDO-COMPOUNDS.

TOLUENE-AZO- compounds *v.* AZO- COMPOUNDS and DISAZO- COMPOUNDS.

TOLUENE-AZOXY- compounds *v.* AZOXY-COMPOUNDS.

TOLUENE CARBOXYLIC ACID *v.* TOLUIC ACID.

Toluene dicarboxylic acid $C_9H_8O_4$ *i.e.* $C_6H_3Me(CO_2H)_2$ [4:2:1]. *Methyl-phthalic acid.* Mol. w. 180. [152°]. Formed from (*a*)-amido-*p*-toluic nitrile by Sandmeyer's reaction, the resulting nitrile being saponified (Niementowski, *M.* 12, 623). V. e. sol. water and alcohol. With *o*-amido-phenol it forms $C_6H_3Me(CO)_2N.C_6H_4OH$ [205°], whence boiling aqueous sodium carbonate gives rise to $C_6H_3Me(CO_2H).CO.NH.C_6H_4.OH$ [200°].

Amide $C_6H_3Me(CONH_2)_2$. [188°]. Formed from the imide and NH_3Aq.

Anhydride. [92°]. Needles.

Imide $C_6H_3Me.C_2O_2.NH$. [196°]. Got by fusing the anhydride with urea. Needles.

Nitrile $C_6H_3Me(CN)_2$. [120°] (N.); [117°] (Glock, *B.* 21, 2663). Needles. Converted by alcohol and HCl into $C_7H_6Cy.C(NH_2Cl).OEt$ [199°].

Toluene dicarboxylic acid $C_6H_3Me(CO_2H)_2$ [4:3:1]. (*β*)-*Xylidic acid. Methyl-isophthalic acid.* [320°-330°]. Formed by oxidation of *m*-xylene carboxylic acid (Jacobsen, *B.* 14, 2112) and of $C_6H_3Me(CH_2.OH)_2$ (Hjelt a. Gadd, *B.* 19, 868). Formed also by fusing potassium toluene *m*-disulphonate or the salt $C_6H_3Me(SO_2NH_2).CO_2K$ with sodium formate (Hakansson, *B.* 5, 1088; Remsen a. Iles, *Am.* 1, 119). The same acid (?) is got by oxidation of $C_6H_3Me_2CO_2H$ [1:4:2] by HNO_3 (S.G. 1·12) at 150° (Claus a. Wollner, *B.* 18, 1858). Small crystals, sl. sol. hot water. May be sublimed.—Ag_2A'': crystals, v. sol. hot water.

Toluene dicarboxylic acid $C_6H_3Me(CO_2H)_2$ [2:4:1]. *Methyl-terephthalic acid.* (*a*)-*Xylidic acid.* [c. 282°]. Formed by boiling pseudocumene with dilute HNO_3 (Fittig a. Laubinger, *A.* 151, 276). Got also by fusing

$C_6H_3Me(SO_2NH_2)CO_2K$ with sodium formate (Remsen a. Iles, *Am.* 1, 114). Needles (by sublimation). Sl. sol. Aq. Oxidised by $KMnO_4$ to trimellitic and isophthalic acids (Krinos, *B.* 10, 1494).—ZnA''. S. 36 at 0°; ·735 at 100°, ·5 at 130° (Jacobsen, *B.* 10, 859).

Toluene dicarboxylic acid $C_6H_3Me(CO_2H)_2$. [310°-315°]. Formed by fusing potassium toluene (γ)-disulphonate with sodium formate (Senhofer, *A.* 164, 134). Minute needles, v. sl. sol. cold water, v. sol. alcohol and ether. May be sublimed.—$BaA''2aq$.—Ag_2A'': amorphous pp.

Toluene ω o-dicarboxylic acid $CO_2H.CH_2.C_6H_4.CO_2H$. [2:1]. *Homophthalic acid v. o-Carboxy-phenyl-acetic acid.*

Nitrile v. o-CYANO-BENZYL CYANIDE.

Toluene ω m-dicarboxylic acid $CO_2H.CH_2.C_6H_4.CO_2H$ [3:1]. Formed by oxidation of *m*-di-ethyl-benzene (Allen a. Underwood, *Bl.* [2] 40, 100). Needles (from alcohol). Sublimes without melting at 200°-210°.—Ag_2A''.

Toluene ω p-dicarboxylic acid $CO_2H.CH_2.C_6H_4.CO_2H$. [285°-288°]. S. 1 at 50°. S. (alcohol) 14·3 at 30°. Formed by the action of dilute (25 p.c.) HCl on the amide (Mellinghoff, *B.* 22, 3215). V. sl. sol. ether and benzene.—Ag_2A'': crystalline pp. The same (?) acid formed by oxidation of C_6H_4PrPr [1:4] yields $BaA''1\frac{1}{2}aq$ (Paterno a. Spica, *B.* 10, 1746).

Amide $CO(NH_2).CH_2.C_6H_4.CO.NH_2$. [235°]. Formed from $CH_2Cy.C_6H_4.Cy$ and H_2SO_4. Small hard nodules.

Amic acid $CO(NH_2).CH_2.C_6H_4.CO_2H$. [261°]. Formed from $CH_2Cy.C_6H_4.CO_2H$ and H_2SO_4. Sl. sol. ether, hot water and alcohol.—AgA': crystalline.

Iso-amic acid $CO_2H.CH_2.C_6H_4.CO.NH_2$. [229°]. Formed from *p*-cyano-phenyl-acetic acid. Crystalline, v. sol. alcohol and hot water.—AgA'. Crystalline.

Nitrile $CH_2Cy.C_6H_4.Cy$. *p-Cyano-benzyl cyanide.* [100°]. (above 360°). Formed from $CH_2Cl.C_6H_4Cy$ and KCy (Mellinghoff, *B.* 22, 3209). Needles, v. sl. sol. hot water, sol. alcohol and ether.

Semi-nitrile $CH_2Cy.C_6H_4.CO_2H$. [201°]. Formed from ω-chloro-*p*-toluic acid by treatment with KOHAq and alcoholic KCy (Mellinghoff, *B.* 22, 3213). Crystalline, v. sol. alcohol and ether.—AgA'.

Semi-nitrile $CO_2H.CH_2.C_6H_4.Cy$. [152°]. Formed from the nitrile and HCl at 105°. Prisms, v. sol. alcohol.—AgA'. Crystalline.

Nitrile-amide $CH_2Cy.C_6H_4.CO.NH_2$. [182°]. Formed from ω-chloro-*p*-toluic amide and KCy. Plates.

Amide-nitrile $CO(NH_2).CH_2.C_6H_4.Cy$. [196·5°]. Formed from the nitrile and HCl at 70°. Crystalline, v. sol. alcohol.

Toluene tri-carboxylic acid $C_6H_2(CO_2H)_2.CH_2.CO_2H$. Formed in small quantity by oxidation of *s*-tri-ethyl-benzene (Friedel a. Balsohn, *Bl.* [2] 34, 635). Needles. Sublimes before melting.—Ag_3A'''. Tables (from hot water).

TOLUENE o-PHOSPHINIC ACID $C_6H_4Me.P(OH)_2$. Obtained by decomposing its chloride with water (Michaelis a. Paneck, *A.* 212, 223). Oil. Monobasic acid.—CaA'_2aq.

Chloride $C_6H_4Me.PCl_2$. (244°). Formed by the action of PCl_3 on mercury ditolyl [107°] and by warming toluene with $AlCl_3$ and PCl_3. Liquid.

Toluene p-phosphinic acid $C_6H_4Me.P(OH)_2$. [105°]. Formed in like manner. Plates, v. sl. sol. water. Oxidised by HNO_3 to the phosphonic acid. Decomposed on heating into tolyl-phosphine and toluene phosphonic acid.—KA'.—NH_4A'.—BaA'_2aq.—PbA'_2.—CuA'_24aq.

Ether $C_6H_4Me.P(OEt)_2$. [280°]. Formed from the chloride and dry NaOEt.

Chloride $C_6H_4Me.PCl_2$. [25°]. (245°). Formed, together with the *o*-isomeride, from toluene, PCl_3, and $AlCl_3$ (Michaelis a. Paneck, *A.* 212, 203). Formed also from $Hg(C_7H_7)_2$ [235°] and PCl_3. Needles, v. sol. ether and benzene.

References.—NITRO- and OXY-TOLUENE PHOSPHINIC ACID.

TOLUENE PHOSPHINIC ANHYDRIDE *v.* PHOSPHINO-TOLUENE.

TOLUENE o-PHOSPHONIC ACID $C_6H_4Me.PO(OH)_2$. [141°]. Formed by the action of water on its chloride (Michaelis a. Paneck, *A.* 212, 231). Crystals, v. sol. water.—Ag_2A''.

Chloride $C_7H_7.PCl_4$. This is formed from $C_7H_7.PCl_2$ and chlorine. Yellow solid.

Toluene p-phosphonic acid $C_6H_4Me.PO(OH)_2$. [189°]. Formed from $C_7H_7.PCl_4$ and cold water. Woolly needles. Oxidised by alkaline $KMnO_4$ to $CO_2H.C_6H_4.PO(OH)_2$. Bromine forms bromo-toluene.—$KH_3A''_2$: needles.—$BaH_2A''_2$—$AgHA''$.—Ag_2A''.

Chloride $C_7H_7.PCl_4$. [42°]. Formed from $C_7H_7PCl_2$ and chlorine. Yellow mass, converted by dry SO_2 into liquid $C_7H_7.POCl_2$ (285°).

Toluene ω-phosphonic acid $C_6H_5.CH_2.PO(OH)_2$. [166°]. Formed, together with $(C_7H_7)_2PO(OH)$ [191°], from benzoic aldehyde and PH_4I (Litthauer, *B.* 22, 2145). Stellate groups of prisms (from HOAc).

Reference.—OXY-TOLUENE PHOSPHONIC ACID.

TOLUENE ω-SELINIC ACID $C_7H_8SeO_2$ *i.e.* $C_6H_5.CH_2.SeO.OH$. [85°]. Formed by oxidising benzyl diselenide with HNO_3 (Jackson, *A.* 179, 8). Needles, sl. sol. cold water, v. sol. alcohol, nearly insol. ether.—AgA': slender crystals (from hot water).

TOLUENE SULPHAMINE *v.* AMIDO-TOLUENE SULPHINIC ACID.

TOLUENE o-SULPHINIC ACID $C_7H_8SO_2$ *i.e.* $C_6H_4Me.SO.OH$. [80°]. Formed by boiling $C_7H_7.N_2H_2.SO_2.C_7H_7$ with baryta-water (Limpricht, *B.* 20, 1241). Long needles, v. sol. ether.—$BaA'_2 3aq$. Nodules, v. sol. water.

Toluene p-sulphinic acid $C_6H_4Me.SO_2H$. [85°]. Formed in like manner (Limpricht), and also from toluene *p*-sulphonic chloride and sodium-amalgam, zinc-dust, or Na_2SO_3 (Otto, *A.* 142, 92; 145, 19; *B.* 9, 1586; Blomstrand, *B.* 3, 965). Plates, v. sol. ether. Fuming HNO_3 forms crystals [190°]. The Na salt heated with $CH_3.CHCl_2$ and alcohol at 150° gives a small quantity of $CH_3.CHCl.SO_2.C_7H_7$ [48°] (Otto, *J. pr.* [2] 40, 519). The Na salt with $ClCO_2Et$ gives the ether (Otto, *B.* 26, 308).—BaA'_2: plates.—$CaA'_2 4aq$.—$ZnA'_2 2aq$.—AgA'.

Methyl ether. Formed from the Na salt and $ClCO_2Et$ in MeOH. Oil (Otto, *J. pr.* [2] 47, 166).

Ethyl ether **EtA′. Oil. Oxidised by $KMnO_4$ in HOAc to toluene *p*-sulphonic ether (Otto a. Rossing, *B.* 19, 1226).**

Toluene *exo*-sulphinic acid $C_6H_5.CH_2.SO_2H$. Prepared by reducing $C_6H_5.CH_2.SO_2Cl$ with sodium-amalgam (Otto a. Lüders, *B.* 13, 1288). Very unstable.—NaA′: leaflets, sol. hot alcohol.

Reference.—AMIDO-TOLUENE SULPHINIC ACID.

TOLUENE *o*-SULPHONIC ACID $C_7H_8SO_3$ *i.e.* $C_6H_4Me.SO_3H$ [1:2].

Formation.—1. In small quantity together with the *p*-isomeride, by dissolving toluene in hot fuming H_2SO_4 (Engelhardt a. Latschinoff, *Z.* [2] 5, 617; Anna Wolkoff, *Z.* [2] 6, 321).—2. Together with the *m*- and *p*- isomerides by the action of $Cl.SO_2.OH$ on toluene (Claesson a. Wallin, *B.* 12, 1848; Noyes, *Am.* 8, 176).—3. From *o*-toluidine by diazotisation followed by treatment with H_2SO_3 (Müller a. Wiesinger, *B.* 12, 1348).—4. By reducing *p*-bromo-toluene sulphonic acid with sodium-amalgam (Terry, *A.* 169, 27).—5. From (4,1,2)- nitro-toluene sulphonic acid by elimination of NO_2 (Jenssen, *A.* 172, 235).

Preparation.—By adding toluene (60 g.) to $ClSO_3H$ (150 g.) in the cold, and pouring the product into water (Noyes).

Properties.—Thin leaflets (containing 2aq), v. sol. water. Deliquescent.

Salts (C. a. W.; Hubner a. Post, *A.* 169, 1).—KA′aq.—NaA′aq: tables, sol. water.—NH_4A': thin leaflets.—CaA'_2: leaflets, sl. sol. water.—BaA'_2aq. S. 4 at 12°. $BaA'_2$4aq.—PbA'_2aq.—$PbA'_2$4aq.—$MgA'_2$7aq.—$ZnA'_2$7aq.—$CuA'_2$4aq.—$CdA'_2$2aq.—$MnA'_2$2aq.—AgA′: sl. sol. water.

Chloride $C_7H_7.SO_2Cl$. Oil.

Amide $C_7H_7.SO_2NH_2$. [154°]. S. ·1 at 9°; S. (alcohol) 3·5 at 5°. Octahedra, sl. sol. water. Yields a benzoyl derivative [112°], which forms $C_7H_7.SO_2.NKBz$ 1½aq and $(C_7H_7.SO_2.NBz)_2Ba$ aq. (Wolkoff, *Z.* [2] 6, 57). Oxidised by $KMnO_4$ in acid solution to *o*-sulpho-benzoic acid and in neutral solution to $C_6H_4\left\langle\begin{matrix}SO_2\\CO\end{matrix}\right\rangle NH$ (Fahlberg a. List, *B.* 21, 242).

Anilide $C_7H_7.SO_2NHPh$. [136°].

Toluide $C_7H_7.SO_2.NHC_7H_7$. [131°].

Toluene *m*-sulphonic acid $C_6H_4Me.SO_3H$ [1:3]. *Formation.*—1. By the action of H_2SO_3 on *m*-diazo-toluene salts (Müller a. Wiesinger, *B.* 12, 1349).—2. A product of the action of $ClSO_3H$ on toluene (Claesson a. Wallin, *B.* 12, 1848).—3. From *o*-bromo-toluene *m*-sulphonic acid and sodium-amalgam (Müller, *A.* 169, 47). 4. By the diazo-reaction from *p*-toluidine sulphonic acid and from *o*-toluidine sulphonic acid (Pechmann, *A.* 173, 202; Pagel, *A.* 176, 297; Nevile a. Winther, *C. J.* 37, 628; Klason, *B.* 19, 2887).

Properties.—Thin deliquescent scales (containing aq), v. sol. water.

Salts.—KA′aq.—NaA′aq.—NH_4A': scales, v. sol. water.—$CaA'_2$3aq: needles, v. sol. water.—$BaA'_2$2aq.—BaA'_2aq. S. 22·75 at 12° (C. a. W.); 15·5 at 15° (Vallin, *B.* 19, 2952).—PbA'_2aq.—$PbA'_2$2aq.—$PbA'_2$3aq.—$MgA'_2$8aq.—$ZnA'_2$6aq.—$ZnA'_2$7aq.—$CdA'_2$5aq.—$CdA'_2$6aq: crystals. $MnA'_2$7aq.—$CuA'_2$4aq.—AgA′: v. sol. water.

Chloride $C_7H_7.SO_2Cl$. Oil.

Amide $C_7H_7.SO_2NH_2$. [108°]. **S. ·4 at 9° (C. a. W.); ·265 at 14° (V.). S. (alcohol) 18 at 5° (C. a. W.); 17·4 at 14° (V.). Monoclinic tables and octahedra (from alcohol). Melts at** 91° according to Noyes. Oxidised by alkaline K_3FeCy_6 to $CO_2H.C_6H_4.SO_2NH_2$ (Noyes a. Walker, *Am.* 8, 187).

Anilide $C_7H_7.SO_2NHPh$. [72°].

m-Toluide $C_7H_7.SO_2.NHC_7H_7$. [103°].

Toluene *p*-sulphonic acid $C_6H_4Me.SO_3H$ [1:4.] The chief product of sulphonation of boiling toluene (Deville, *A. Ch.* [3] 3, 172; Fittig a. Tollens, *A.* 131, 310; Mürcker, *A.* 136, 85; Engelhardt a. Latschinoff, *Z.* [2] 5, 617; Jaworsky, *Z.* 1865, 221; Otto a. Gruber, *A.* 142, 92; 145, 10; Chrustshoff, *B.* 7, 1167; Fahlberg, *B.* 12, 1048).—2. From toluene and $ClSO_3H$ (Claesson a. Wallin, *B.* 12, 1848).—3. By the action of H_2SO_3 on *p*-diazo-toluene salts (M. a. W.).

Properties.—Thick leaflets or flat prisms (containing aq). Deliquescent. Melts at 92° (Norton a. Otten, *Am.* 10, 110). Fusion with sodium formate yields *p*-toluic acid (Remsen, *B.* 8, 1412). Potash-fusion gives *p*-cresol. Hydrolysis by steam begins at 150° (Armstrong a. Miller, *C. J.* 45, 148).

Salts. KA′aq. Trimetric crystals; *a*:*b*:*c* = ·864:1:3·237.—NaA′3aq. NaA′2aq.—NH_4A'.—$CaA'_2$4aq.—BaA'_2. BaA'_2aq. S. 21 at 12°.—$BaA'_2$3aq (Kelbe, *B.* 16, 621).—PbA'_2.—$MgA'_2$6aq. $ZnA'_2$6aq. $CdA'_2$6aq.—$MnA'_2$6aq.—$CuA'_2$6aq.—AgA′: long plates, v. sol. water.

Methylamine salt [125°].—NMe_2H_2A'. [78°].—NMe_3HA'. [92°]. Aniline salt [223°].—*o*-Toluidine salt [180°] (N. a. O.).

Chloride $C_7H_7.SO_2Cl$. [69°]. Triclinic crystals; *a*:*b*:*c* = ·768:1:1·114; α = 97° 24′; β = 117° 6′; γ = 84° 28′. Acetoxim and NaOH form $C_7H_7.SO_2.O.N{:}CMe_2$ [89°] (Wege, *B.* 24, 3538). In ethereal solution it is reduced by sodium-amalgam to toluene sulphinic acid and the compound $C_8H_{10}SO_2$ [76°]. In presence of isoamyl ether $(C_5H_{11})_2O$ the compound $C_{12}H_{18}S_2O_4$ [36°] is formed (Otto, *A.* 143, 216).

Bromide $C_7H_7.SO_2Br$. [96°].

Iodide $C_7H_7.SO_2I$. [85°]. Formed by adding an alcoholic solution of I to aqueous $C_7H_7.SO_2Na$ (Otto a. Tröger, *B.* 24, 479). Yellow crystalline powder, v. sol. ether, turning brown in air. Heated with water at 100° it forms $C_7H_7.S_2O_2.C_7H_7$. Reduced silver acts in like manner. $ZnEt_2$ forms zinc toluene sulphinate.

Methyl ether MeA′. [c. 30°].

Ethyl ether EtA′. [32°]. S.G. ^{32} **1·174.** Thick prisms (Kraft a. Roos, *B.* 25, 2259).

Phenyl ether $C_7H_7.SO.OPh$. [95°]. **Formed** by the action of NaOPh on the chloride **dissolved** in benzene (Otto, *B.* 19, 1832). Trimetric **crystals**; *a*:*b*:*c* = ·289: [illegible] ·476. Not affected by alcoholic NH_3, even at 200°.

Amide $C_7H_7.SO_2NH_2$. [136°]. **S. ·2 at 9°.** S. (alcohol) 7·4 at 5°. **Leaflets. Yields** $C_7H_7.SO_2NHK$ aq. BzCl forms $C_7H_7.SO_2.NHBz$ [147°-150°], which gives KA′, CaA'_2aq, BaA'_2, AgA′, and $AgA'NH_3$, and is converted by PCl_5 into $C_7H_7SO_2N{:}CCl.C_6H_5$ [100°], whence ammonium carbonate solution forms $C_{14}H_{14}N_2SO_2$ [114°] (Wolkoff, *B.* 5, 140). Succinyl chloride forms crystalline $C_7H_7.SO_2.NC_4H_4O_2$, converted by NH_3Aq into $C_7H_7.SO_2.N_2H_3(C_4H_4O_2)$ [180°] and

$(C_7H_7SO_2)_2N_2H_4(C_4H_4O_2)$, which crystallises from alcohol (Wolkoff. *Z.* 1870, 580).

Methylamide $C_7H_7.SO_2.NHMe$. [75°]. Rectangular plates, sl. sol. hot water. Yields $C_7H_7.SO_2.NBzMe$ [58°].

Ethylamide $C_7H_7.SO_2.NHEt$. [58°].

Anilide $C_7H_7.SO_2NHPh$. [103°]. BzCl forms $C_7H_7.SO_2NBzPh$ [149° cor.] (Remsen a. Palmer, *Am.* 8, 242).

Methylanilide $C_7H_7.SO_2.NMePh$ [95°]. Monoclinic crystals (Otto, *J. pr.* [2] 47, 371).

Ethyl-anilide [88°]. Prisms, insol. water.

p-Toluide $C_7H_7.SO_2NHC_7H_7$. [118°].

Toluene *exo*-**sulphonic acid** $C_6H_5.CH_2.SO_3H$. Formed by boiling benzyl chloride with aqueous K_2SO_3 (Böhler, *A.* 154, 50; 221, 215; Mohr, *A.* 221, 216; Otto a. Lüders, *B.* 13, 1286). Formed also by oxidising benzyl disulphide with HNO_3 (Barbaglia, *B.* 5, 270, 688), and also, together with acetic acid, by heating benzyl methyl ketone with H_2SO_4 (Krekeler, *B.* 19, 2625). Very hygroscopic crystals. The K salt heated with KCy yields $C_6H_5.CH_2.CN$.

Salts.—NH_4A'.—KA'aq. Trimetric prisms. —BaA'_2 2aq. Plates, sl. sol. water.—CaA'_2 2aq.— $PbA'(OH)$: crystals.—PbA'_2.—AgA': crystalline.

Chloride $C_6H_5.CH_2.SO_2Cl$. [93°]. Decomposed by heat into SO_2 and benzyl chloride.

Amide $C_6H_5.CH_2.SO_2NH_2$. [102°] (O. a. L.) [105°] (Pechmann, *B.* 6, 534). Needles, sol. water and alcohol.

Toluene (α)-**disulphonic acid** $C_6H_3Me(SO_3H)_2$ [1:2:4]. Formed by sulphonation of toluene and of toluene *o*- or *p*-sulphonic acid (Hakansson, *B.* 5, 1084; Senhofer, *A.* 164, 129; Gnehm a. Forrer, *B.* 10, 542; Claesson a. Berg, *B.* 13, 1170; Klason, *B.* 20, 354). Formed also by heating toluene *p*-sulphonic chloride with H_2SO_4 (Fahlberg, *B.* 12, 1052; *Am.* 1, 170; 2, 182). Thick liquid.—$(NH_4)_2A''$aq.—K_2A''aq.—BaA''aq. S. ·75 at 17°. Insol. alcohol.—Ag_2A'' 2aq.

Chloride $C_7H_6(SO_2Cl)_2$. [52°].

Amide $C_7H_6(SO_2NH_2)_2$. [186°].

Toluene (β)-**disulphonic acid** $C_6H_3Me(SO_3H)_2$ [1:2:5]. Formed by heating toluene *o*-sulphonic acid with fuming H_2SO_4 at 160° (H.), or toluene *m*-sulphonic acid with H_2SO_4 at 180° (Klason, *B.* 19, 2889; 20, 352).—K_2A'' aq.—BaA'' aq. S. 3·9 at 15° (K.).

Chloride $C_6H_3Me(SO_2Cl)_2$. [96°].

Amide $C_6H_3Me(SO_2NH_2)_2$. [224°].

Toluene disulphonic acid $C_6H_3Me(SO_3H)_2$ [1:2:3]. Formed by the action of sodium-amalgam on *p*-iodo-toluene disulphonic acid (Limpricht a. E. Richter, *B.* 18, 2179; *A.* 230, 326), and by heating toluene *m*-sulphonic acid with fuming H_2SO_4 at 180° (Klason). Slender needles, v. sol. water and alcohol.—K_2A'' aq.— BaA'' $3\frac{1}{2}$aq. Prisms, v. sol. water.

Chloride $C_6H_3Me(SO_2Cl)_2$. [95°].

Amide $C_6H_3Me(SO_2NH_2)_2$. [214°].

Toluene *o*-**disulphonic acid** $C_6H_3Me(SO_3H)_2$. [1:2:6]. Formed by reduction of *p*-bromo-toluene disulphonic acid with sodium-amalgam (Kornatzki, *A.* 221, 199).—K_2A''.—BaA'' 4aq. V. e. sol. water.

Chloride [86·5°]. Prisms (from ligroïn).

Amide [above 260°]. Needles, v. sol. Aq.

Toluene disulphonic acid $C_6H_3Me(SO_3H)_2$ [1:3:4]. Formed from *p*-toluidine sulphonic acid by conversion into $C_6H_3Me(SH).SO_3H$ and oxidation of the product (Klason, *B.* 20, 356).— K_2A'' aq.—BaA'' 2aq. S 15. Prisms.

Chloride. [111°]. V. sol. $CHCl_3$.

Amide. [235°–239°]. V. sol. water.

Toluene-*s*-disulphonic acid $C_6H_3Me(SO_3H)_2$ [1:3:5]. Formed from *o*-iodo- (or bromo-) toluene disulphonic acid or *o*-diazo-toluene disulphonic acid by long boiling with conc. HI (Limpricht a. Hasse, *B.* 18, 2177; *A.* 230, 295).—K_2A'' $2\frac{1}{2}$aq.—$(NH_4)_2A''$.

Chloride [132°]. Long prisms.

Amide [over 240°]. Small plates.

Toluene trisulphonic acid $C_6H_2Me(SO_3H)_3$. Formed by heating sodium toluene (α)-disulphonate with $ClSO_3H$ at 240° (Claësson, *B.* 14, 307). Slender needles (containing 6aq), v. sol. water. Salts.—K_3A''' $3\frac{1}{2}$aq.—$Pb_3A'''_2$ 8aq.— $Ba_3A'''_2$ 14aq. Crystals, v. sol. water.

Chloride $C_6H_2Me(SO_2Cl)_3$. [153°].

Amide $C_6H_2Me(SO_2NH_2)_3$. [above 300°]. Minute crystals, nearly insol. water.

References.—Amido-, Bromo-, Bromo-amido-, Bromo-nitro-, Chloro-, Iodo-, Iodo-amido-, Nitro-amido-, Nitro- and Oxy- toluene sulphonic acid.

TOLUENE *p*-THIOSULPHONIC ACID $C_6H_4Me.SO_2.SH$. Formed by heating a solution of a salt of toluene *p*-sulphinic acid with sulphur (Otto, *B.* 15, 129; 20, 2087) or by adding a mixture of Na_2S and $C_7H_7.SO_2Na$ to an alcoholic solution of iodine (Otto a. Tröger, *B.* 24, 1132). A solution of Na salt gives a white pp. of cuprous salt on adding $CuSO_4$.

Reactions.—1. *Iodine* added to an alcoholic solution of the K salt forms the three compounds $(C_7H_7SO_2)_2S$ [134°], $(C_7H_7SO_2)_2S_2$ [109°], and $(C_7H_7SO_2)_2S_3$ [182°]. The compound $(C_7H_7SO_2)_2S$ is also formed by the action of I on a mixture of $C_7H_7.SO_2SNa$ and $C_7H_7SO_2Na$, and crystallises from benzene in monoclinic forms $a:b:c = 2·829:1:3·221$; $\beta = 60°\ 7'$. The compound $(C_7H_7SO_2)_2S_2$ is split up by boiling HOAc into $(C_7H_7SO_2)_2S$ and $(C_7H_7SO_2)_2S_3$ (Otto a. Tröger, *B.* 24, 1126).—2. $Cl.CO_2Et$ acting on the Na salt forms the ethyl and tolyl ethers and the compound $(C_7H_7SO_2)_2S_3$ [182°] (Otto a. Rössing, *B.* 24, 1148).

Salts.—NaA' 2aq. Trimetric tables.— KA' 2aq.—AgA'aq: small tables, sl. sol. water.

Ethyl ether $C_7H_7.SO_2.SEt$. *Tolyl ethyl disulphoxide.* Got from NaA' and EtI. Oil.

Ethylene ether $C_2H_4A'_2$. [77°]. Needles. Decomposed by zinc-dust into the zinc salts of toluene sulphinic acid and ethylene mercaptan (Otto a. Heydecke, *B.* 25, 1478).

Tolyl ether $C_7H_7.SO_2.SC_7H_7$. *Tolyl disulphoxide.* [78°]. Formed by oxidation of *p*-tolyl mercaptan (Märcker, *A.* 136, 83). Formed also from toluene *p*-sulphonic acid and water at 100° (Otto a. Tröger, *B.* 24, 480). Monoclinic prisms (from alcohol). Decomposed on saponification by alkalis into toluene *p*-sulphonic acid and di-tolyl disulphide [41°] (Otto a. Rössing, *B.* 19, 1240). Reduced by zinc and dilute H_2SO_4 to tolyl mercaptan. Bromine forms $(C_{14}H_{14}S_2O_2)_2Br_2$ (Otto a. Grüber, *A.* 149, 105). Alcoholic H_2S forms, on warming, toluene *p*-sulphinic acid, di-tolyl disulphide, and tolyl tetrasulphide.

Reference.—Amido-toluene thiosulphonic acid.

TOLUENYL- *v.* Tolenyl-.

o-TOLUIC ACID $C_6H_4Me.CO_2H$ [1:2]. Mol. w. 136. [104°]. H.C.v. 928,800. H.C.p. 929,400. H.F. 98,600 (Stohmann, *J. pr.* [2] 40, 133).

Formation.—1. By oxidation of *o*-xylene with dilute HNO_3 (Bieber a. Fittig, *Z.* [2] 6, 496; *A.* 156, 242).—2. From toluene *o*-sulphonic acid *viâ* $C_7H_7.CN$ (Ramsay a. Fittig, *Z.* [2] 7, 584; *A.* 168, 246).—3. By the action of sodium-amalgam on a mixture of $ClCO_2Et$ and *o*-iodo-toluene and saponification of the resulting $C_7H_7.CO_2Et$ (Kekulé, *B.* 7, 1007).—4. By boiling phthalide (3 mols.) with HIAq (127°) and yellow P (2 at.), the yield being 97 p.c. (Hessert, *B.* 11, 238; Racine, *A.* 239, 72).—5. From *o*-toluidine *viâ* the nitrile (Cahn, *A.* 240, 280).

Properties.—Plates (containing 2aq), volatile with steam, sl. sol. cold water. Oxidised by alkaline $KMnO_4$ to phthalic acid (Weith, *B.* 7, 1057). Bromine-vapour above 100° forms phthalide; in the cold Br forms bromo-toluic acid $C_6H_3MeBr.CO_2H$ [167°].

Salts.—NaA′ 2aq. [228°]. Efflorescent plates.—CaA'_2 2aq.—BaA'_2 2aq.

Ethyl ether EtA′. (220°).

Amido-ethyl ether $C_7H_7.CO.O.CH_2.CH_2.NH_2$. Formed from *o*-tolyl-oxazoline and HClAq. Oil. Yields B′HBr [156°], $B'C_6H_3N_3O_7$ [188°].

Amido-propyl ether $C_7H_7.CO.O.CHMe.CH_2.NH_2$. Formed by evaporating tolyl-methyl-oxazoline with HClAq. Yields B′HBr [140°], $B'C_6H_3N_3O_7$ [192°], and a platinochloride [214°].

Benzyl ether C_7H_7A'. (315°). S.G. $\frac{17}{17}$ 1·12. Oil (Hodgkinson, *C. J. Proc.* No. 103, p. 167).

Chloride C_8H_7OCl. (211° at 733 mm.).

Anhydride $(C_7H_7.CO)_2O$. [c. 38°]. (above 325°). Formed from the Na salt (6 mols.) and $POCl_3$ (1 mol.). Insol. water, sol. ether and benzene.

Amide $C_7H_7.CONH_2$. [140°] (Hutchinson, *B.* 24, 174; *C. J.* 57, 957; *cf.* Weith, *B.* 6, 420). On reduction in acid solution it yields *o*-tolyl alcohol and a small quantity of the dihydride $C_7H_9.CO.NH_2$ [156°], which on boiling with water yields an acid [68°]. The dihydride is also formed by reducing the amide in alkaline solution.

Anilide $C_7H_7.CO.NHPh$. [125°]. Formed from *anti*-phenyl-*o*-tolyl ketoxim and PCl_5 followed by water (Smith, *B.* 24, 4017).

Xylide $C_7H_7.CO.NHC_6H_3Me_2$ [1:2:4]. [165°]. Formed by heating *o*-tolyl xylyl ketone with hydroxylamine at 120° (Smith).

Bromo-ethylamide $C_7H_7.CO.NH.CH_2.CH_2Br$. [71°] (Salomon, *B.* 26, 1322).

Chloro-ethylamide $C_7H_7.CO.NH.CH_2.CH_2Cl$. [73°]. White needles.

Bromo-propyl-amide $C_7H_7.CO.NH.CH_2.CHBr.CH_3$. [86°]. Needles (from benzene-ligroïn) (Salomon, *B.* 26, 1323).

Chloro-propyl-amide $C_7H_7.CO.NH.CH_2.CHMeCl$. [84°]. Formed by evaporating *o*-tolyl-methyl-oxazoline with excess of HClAq. Needles (from ligroïn).

o-Nitro-benzyl-amide $C_7H_7.CO.NH.CH_2.C_6H_4.NO_2$. [135°]. Needles (from alcohol). May be reduced to the *o*-amido-benzyl-amide [116°], which yields B′HCl [214°] (Wolff, *B.* 25, 3034).

Imide $(C_7H_7.CO)_2NH$. [148°].

Nitrile $C_7H_7.CN$. (204° cor.). V.D. 4·03 (obs.). H.F. −34,800 (Berthelot a. Petit, *A. Ch.* [6] 17, 123). Formed by heating KCy with potassium toluene *o*-sulphonate or with tri-*o*-tolyl phosphate (Heim, *B.* 16, 1776), by heating *o*-tolyl thiocarbimide with finely-divided copper (Weith, *B.* 6, 419), by boiling *o*-tolyl carbamine (Weith, *B.* 7, 722), by heating *o*-iodo-toluene with AgCy at 350° (Merz a. Weith, *B.* 10, 751), by boiling the formyl derivative of *o*-toluidine with zinc-dust (the yield being 18 p.c.) (Gasiorowski a. Merz, *B.* 17, 74; 18, 1004), and by Sandmeyer's reaction from *o*-toluidine (Cahn, *B.* 19, 756). Liquid. H_2SO_4 at 60° to 70° forms $C_7H_7.C(NH).NH.CO.C_7H_7$ [103°], which is converted, by warming its acid solution, into the imide $(C_7H_7.CO)_2NH$ (Krafft a. Kerstens, *B.* 25, 455). Conc. HIAq forms $C_7H_7.CI_2.NH_2$ [98°] (Biltz, *B.* 25, 2540).

Hexahydride *v.* Methyl-hexamethylene carboxylic acid.

m-**Toluic acid** $C_6H_4Me.CO_2H$ [1:3]. [110°] (Jacobsen, *B.* 14, 2347; Bornemann, *B.* 20, 1382). (263°). H.C.v. 928,500. H.C.p. 929,100. H.F. 98,900 (Stohmann, *J. pr.* [2] 40, 134). S. ·09 at 15°; 1·66 at 100°.

Formation. 1. By oxidising bromo-xylene and reducing the resulting bromo-toluic acid with sodium-amalgam (Ahrens, *Z.* [2] 5, 106; Richter, *B.* 5, 421; Böttinger a. Ramsay, *A.* 168, 255). 2. By distilling uvitic acid with lime (Fittig, *B.* 5, 268). 3. By oxidation of *m*-xylene with dilute HNO_3 (Tawildaroff, *B.* 4, 410; Bruckner, *B.* 9, 406; Reuter, *B.* 17, 2028).—4. By saponifying the nitrile.

Preparation.—1. By boiling ω-chloro-xylene with HNO_3 (1 vol. of S.G. 1·4) and water (3 vols.) (Senff, *A.* 220, 247).—2. By sulphonating crude xylene, then preparing $C_6H_3Me_2.SO_2NH_2$, oxidising by $KMnO_4$, heating the resulting $C_6H_3Me(SO_2NH_2).CO_2H$ with HCl at 230°, and distilling with steam (Jacobsen, *B.* 14, 2347).

Properties.—Long needles, volatile with steam, v. sol. alcohol and ether. Oxidised by chromic acid mixture to isophthalic acid.

Salts.—CaA'_2 3aq. S. 3·17 at 15°; 8·2 at 100°.—BaA'_2 2aq: trimetric plates or tables.—AgA′.

Ethyl ether EtA′. (226°).

Chloride (218° at 724 mm.) (Ador a. Rilliet, *B.* 12, 2300).

Nitrile $C_7H_7.CN$. (209°). Formed by heating *m*-tolyl thiocarbimide with Cu (Weith a. Landolt, *B.* 8, 720), and in other ways (Buchka a. Schachtebeck, *B.* 22, 841).

p-**Toluic acid** $C_6H_4Me.CO_2H$ [1:4]. [179°]. (275° cor.) (Fischli, *B.* 12, 615). H.C.v. 926,800. H.C.p. 927,400. H.F. 100,600 (Stohmann, *J. pr.* [2] 40, 134).

Formation.—1. By the action of dilute NHO_3 on cymene (Noad, *P. M.* [3] 32, 19; *A.* 63, 289) on *p*-xylene (Beilstein, *A.* 137, 302; Brückner, *A.* 205, 113), and on terpenes (Hirzel, *Z.* 1866, 205).—2. By saponification of the nitrile.—3. By heating *p*-bromo-toluene with $ClCO_2Et$ and sodium-amalgam and saponifying the product (Wurtz, *C. R.* 68, 1298).—4. From *p*-bromo-toluene, CO_2, and sodium (Kekulé, *A.*

187, 184).—5. By the action of $POCl_3$ (40 g.) on a mixture of toluene (40 g.), HOAc (80 g.) and $ZnCl_2$ (80 g.) at 110° (Frey, *J. pr.* [2] 43, 116).—6. By reducing bromo-*p*-toluic acid with sodium-amalgam (Remsen a. Morse, *Am.* 1, 138).—7. From the chloride which is formed by the action of $COCl_2$ on toluene in presence of $AlCl_3$ (Ador a. Crafts, *B.* 10, 2176).—8. From the amide which is formed by the action of $AlCl_3$ on a mixture of toluene, CS_2, and $NH_2.CO.Cl$ (Gattermann a. Schmidt, *B.* 20, 859).—9. By fusing $C_7H_7.CO.C_6H_4.CO_2H$ with potash (Friedel a. Crafts, *Bl.* [2] 35, 508), and also by passing gaseous cyanic acid and HCl into toluene at 100° containing $AlCl_3$ (Gattermann a. Rossolymo, *B.* 23, 1195).

Properties.—Needles, v. sol. hot water, v. e. sol. alcohol and ether. Volatile with steam. Oxidised by CrO_3 or $KMnO_4$ to terephthalic acid. Yields a di-nitro-derivative [158°].

Salts.—KA′.—BaA'_2 2aq: needles (Buchka a. Irish, *B.* 20, 1764).—CaA'_2 3aq.—MgA'_2 3aq.—CuA'_2.—AgA′.

Methyl ether MeA′. [32°]. (217°).

Ethyl ether EtA′. (228°). Oil.

Amido-ethyl ether $C_7H_7.CO.O.C_2H_4NH_2$. Yields B′HBr [167°] and $B'C_6H_3N_3O_7$ [180°].

p-Amido-propyl ether $C_7H_7.CO.O.C_3H_6.NH_2$. The hydrobromide B′HBr is formed by evaporating a solution of the bromo-propyl-amide. It yields $B'C_6H_3N_3O_7$ [186°] and $B'_2H_2PtCl_6$.

Phenyl ether PhA′. [72°].

Chloride (225° at 720 mm.).

Amide $C_7H_7.CO.NH_2$. [159°]. Formed by heating the NH_4 salt in sealed tubes at 230° (Hallemann, *R. T. C.* 6, 79).

Methylamide $C_7H_7.CO.NHMe$. [143°]. Formed by the action of NHMe.COCl on toluene in presence of $AlCl_3$ (Gattermann a. Schmidt, *B.* 20, 120; *A.* 244, 51). Tables.

Ethylamide $C_7H_7.CO.NHEt$. [96°].

Bromo-ethyl-amide $C_7H_7.CO.NH.CH_2.CH_2Br$. [129°] (Salomon, *B.* 26, 1325). Formed from *p*-toluic chloride and bromo-ethylamine. Plates. Converted by boiling water into the amido-ethyl ether.

Chloro-ethyl-amide $C_7H_7.CO.NH.CH_2.CH_2Cl$. [122°]. Needles (from ligroïn).

Bromo-propyl-amide $C_7H_7.CO.NH.CH_2.CHBr.CH_3$. Melts at 74°, becomes solid, and melts again at 158° (*B.* 26, 1326).

Chloro-propyl-amide $C_7H_7.CO.NH.CH_2.CHMeCl$. [78°].

Anilide $C_7H_7.CO.NHPh$. [145°]. Formed from toluene, phenyl cyanate, and $AlCl_3$ (Leuckart, *J. pr.* [2] 41, 306).

o-Nitro-anilide. [110°]. Yellow prisms.

p-Toluide $C_7H_7.CO.NHC_7H_7$. [160°]. Formed by the action of sodium-amalgam and HOAc at 60° on an alcoholic solution of di-*p*-tolyl ketoxim (Goldschmidt a. Stöcker, *B.* 23, 2747; 24, 2799). Needles.

Nitro-toluide $C_7H_7.CO.NHC_6H_3Me(NO_2)$ [4:1:3]. [166°].

Diphenylamide $C_7H_7.CO.NPh_2$. [155°]. Prisms (from alcohol) (Lellmann a. Bonhöffer, *B.* 20, 2118).

Xylide $C_7H_7.CO.NHC_6H_3Me_2$. [139°]. Yields $C_7H_7.CO.NH.C_6H_2Me_2(NO_2)$ [187°].

Phenyl-methyl-amide $C_7H_7.CO.NPhMe$. [70°] (Lellmann a. Benz, *B.* 24, 2114).

o-Nitro-benzyl-amide $C_7H_7.CO.NH.CH_2.C_6H_4.NO_2$. [142°] (Wolff, *B.* 25, 3036).

Nitrile $C_6H_4Me.CN$. [28·5°]. (218°). Formed by distilling potassium toluene *p*-sulphonate with KCy (Merz, *Z.* [2] 4, 33), by heating $C_7H_7.N.CS$ with Cu (Weith, *B.* 6, 421), by heating tri-*p*-tolyl phosphate with KCy (Heim, *B.* 16, 1775), and by passing $C_7H_7.NH.CHO$ over heated zinc-dust (G. a. M.). Obtained also from *p*-toluidine by Sandmeyer's reaction (Glock, *B.* 21, 2650). Sodium added to its boiling alcoholic solution forms a small quantity of ω-amido-*p*-xylene, the greater part being saponified (Bamberger a. Lodter, *B.* 20, 1710). H_2SO_4 gives $C_7H_7.C(NH).NH.CO.C_7H_7$ [145°]. Easily converted into the imide $(C_7H_7.CO)_2NH$ [155°] (Krafft a. Karstens, *B.* 25, 454). Conc. HIAq forms $C_7H_7.CI_2.NH_2$ [115°–120°], decomposed by fusion (Biltz, *B.* 25, 2539).

Tetrahydride $C_8H_{12}O_2$. (252°). Formed by reduction of $CH_2:C\!\left\langle\begin{smallmatrix}CH_2.CH\\ CH:CH\end{smallmatrix}\right\rangle\!C.CO_2H$ with sodium-amalgam (Einhorn a. Willstälter, *B.* 26, 2009). Needles, melting below 0°. Yields CaA'_2 4aq, CuA'_2 2aq, MeA′. (210°–220°), and an *amide* [158°]. Boiling NaOHAq converts the acid into a solid isomeride [47°] (254°–260°) which yields CaA'_2 4aq and an amide [135°].

Hexahydride (Serebojakoff, *B.* 25, 3355).

References.—AMIDO-, BROMO-, BROMO-NITRO-, CHLORO-, NITRO-, NITRO-AMIDO-, OXY-, OXY-AMIDO-, and SULPHO- TOLUIC ACID.

α-Toluic acid is PHENYL-ACETIC ACID.

o-TOLUIC ALDEHYDE $C_6H_4Me.CHO[1:2]$. *o-Toluylic aldehyde.* (200°). Prepared by boiling ω-chloro-*o*-xylene with lead nitrate solution (Lauth a. Grimaux, *Bl.* [2] 7, 233; Rayman, *Bl.* [2] 27, 498). Prepared also from *o*-xylene by the successive action of CrO_2Cl_2 and water (Bornemann, *B.* 17, 1467), and by oxidising $C_6H_4Me.CH_2OH$ with chromic acid mixture (Kröber, *B.* 23, 1029). Oil, smelling like bitter almonds. Yields a crystalline compound with $NaHSO_3$. Reduced by sodium-amalgam to *o*-tolyl-carbinol.

Oxim $C_6H_4Me.CH:NOH$. [49°]. Is an *anti-oxim.* White crystals (from ether), v. sol. alcohol. Yields a crystalline hydrochloride. Ac_2O yields an acetyl derivative [56°]. AcCl acts in like manner. The acetyl derivative is decomposed by alkalis with regeneration of the oxim, no nitrile being formed (Dollfus, *B.* 25, 1921). The oxim is converted in ethereal solution by PCl_5 into the nitrile (204°).

***m*-Toluic aldehyde** $C_6H_4Me.CHO[1:3]$. (199°). S.G. ⁰ 1·037. Formed by boiling ω-chloro-*m*-xylene or ω-bromo-*m*-xylene with lead nitrate solution (Gundelach, *Bl.* [2] 26, 44; Müller, *B.* 20, 1213), and also by the action of water on $C_7H_8CrO_2Cl_2$ obtained from *m*-xylene (Étard, *B.* 14, 848; Bornemann, *B.* 17, 1464). Oil, smelling like almonds. Combines with $NaHSO_3$. Aniline forms $C_7H_7.CH:NPh$. (314°).

Phenyl-hydrazide $C_6H_4Me.CH:N_2HPh$. [91°]. (B.); [88°] (Rudolph, *A.* 248, 100). Prisms (from ligroïn), v. sol. ether.

p-Toluic aldehyde $C_6H_4Me.CHO$[1:4]. (205°). Formed by distilling calcium p-toluate with calcium formate (Cannizzaro, *A.* 124, 254). Formed also by the action of water on the product of combination of p-xylene with CrO_2Cl_2 (Bornemann). Oil, with peppery smell. Oxidised by air to toluic acid. Alcoholic potash forms potassium toluate and tolyl-carbinol.

Reference.—NITRO- and OXY-TOLUIC ALDEHYDE.

TOLUIC CHLORIDE *v. Chloride* of TOLUIC ACID.

TOLUIDES. Compounds derived from toluidine by displacement of H in NH_2 by an acid radicle.

o-TOLUIDINE $C_6H_4Me.NH_2$ [1:2]. Mol. w. 107. (198°). S.G. $\frac{20}{4}$ ·9986 (Brühl, *A.* 200, 189). H.C.p. 964,700. H.C.v. 963,750. H.F. 3,800 (Petit, *C. R.* 107, 266). μ_β 1·5895. R_∞ 57·56. S.V. 126·6. Formed from o-cresol, $ZnBr_2$, NH_3, and NH_4Cl at 335° (Merz a. Müller, *B.* 20, 547). Prepared by reduction of o-nitro-toluene. May be separated from p-toluidine by means of the acid oxalates (Bindschedler, *B.* 6, 448; Ihle, *J. pr.* [2] 14, 449; Miniati, Booth a. Cohen, *S. C. I.* 6, 418), by freezing (Rosenstiehl, *Bl.* [2] 17, 7), by means of the nitrates (Schad, *B.* 6, 1361), hydrochlorides, sulphates, or phosphates (Lewy, *Fr.* 23, 269; *B.* 19, 1717, 2728; *cf.* Wülfing, *B.* 19, 2132). o-Toluidine can be prepared from $C_6MeHBr(NH_2)(NO_2)H$ *viâ* $C_6MeHBrI(NO_2)H$, $C_6MeHBrI(NH_2)H$, $C_6MeHBrIBrH$, followed by $C_6Me(NO_2)BrIBrH$, and $C_6Me(NH_2)BrIBrH$. It can also be got from $C_6Me(NH_2)BrIBrH$ *viâ* $C_6MeIBrIBrH$, followed by $C_6MeIBrIBr(NO_2)$ and $C_6MeIBrIBr(NH_2)$ thus proving that the toluidine $C_6H_4Me(NH_2)$ [1:2] is identical with $C_6H_4Me(NH_2)$ [1:6] (Wroblewsky, *A.* 192, 213).

Properties.—Oil. A solution in $H_2SO_4H_2O$ is coloured orange by HNO_3 and blue by CrO_3, the solution in the latter case becoming reddish-violet on dilution. Forms a crystalline compound with liquid CO_2 at 8° (Bitte, *C. R.* 105, 614). With PbO_2 and aqueous acetic acid gives a green colour, while PbO_2 and alcoholic acetic acid gives a reddish-violet colour (Lauth, *C. R.* 111, 975). Unlike p-toluidine, it forms a crystalline compound with alloxan (Pellizzari, *C. C.* 1887, 1288, 1396). If an ethereal solution of o-toluidine is shaken with very dilute bleaching-powder solution the aqueous layer becomes yellow or brown, and the ethereal layer, if decanted and shaken with dilute H_2SO_4, colours this reddish-violet. A solution of p-tolylene diamine hydrochloride mixed with a little o-toluidine gives a green colour on addition of $FeCl_3$ or $K_2Cr_2O_7$ (Nietzki, *B.* 10, 1157).

Reactions.—1. $POCl_3$ forms $PO(NHC_7H_7)_3$ [225°] (Michaelis a. Rudert, *B.* 26, 565), v. sol. water, whence Br forms $PO(NHC_6H_3BrMe)_3$ [253°]. Another product of the action of $POCl_3$ on o-toluidine is $POCl(NHC_6H_4Me)_2$, whence water forms $HO.PO(NHC_7H_7)_2$ [95°]. $PSCl_3$ forms $PS(NHC_7H_7)_3$ [135°].—2. $SiCl_4$ reacts forming $SiCl_2(NHC_7H_7)_2$, a white granular powder (Harden, *C. J.* 51, 40).—3. On heating with *malic acid* it yields the mono-toluide [178°], di-toluide [181°], and a tolyl-imide [116°] of malic acid (Bischoff, *B.* 23, 2043).—4. *Chloro-citryl chloride* forms

$C_7H_7.N{<}\begin{array}{l}CO.CH\\CO.\ddot{C}.CH_2.CO.NHC_7H_7\end{array}$ [214°] (Skinner a. Ruhemann, *C. J.* 55, 239).—5. SO_2, alcohol, and nitrous acid give rise to the 'sulphazide' $C_{14}H_{16}N_2SO_2$ [142°] (Limpricht, *B.* 20, 1241).—6. On *nitration* of o-toluidine or its acetyl derivative NO_2 enters the p- and o- positions, but in presence of H_2SO_4 (10 pts.) the compound $C_6H_3Me(NO_2)(NH_2)$ [1:4:6] [107°] is formed (Nölting a. Collin, *B.* 17, 265), together with the (1,2,6)-isomeride (Green a. Lawson, *C. J.* 59, 1013).—7. *Benzoic aldehyde* forms $C_6H_5CH:NC_7H_7$, an oil (316°) (Étard, *Bl.* [2] 39, 530; Pictet, *B.* 19, 1063). 8. *Hydrobenzamide* on warming forms the same body (310°) (Lachovitch, *M.* 9, 695).—9. Toluidine heated with toluidine hydrochloride and benzoic aldehyde in sealed tubes at 120° forms $C_6H_5.CH(C_6H_3Me.NH_2)_2$, a crystalline powder turning blue in the air (Ullmann, *J. pr.* [2] 36, 251).—10. The *methyl derivative* of *p-oxy-benzoic aldehyde* at 120° produces the compound $C_6H_4(OMe).CH:N.C_7H_7$ [32°] (Steinhart, *A.* 241, 340). 11. *Bromo-propionic acid* reacts, forming $C_{17}H_{18}N_2O_2$ [185°] (Mabery a. Krause, *B.* 22, 3308).—12. *αβ-Di-bromo-acrylic acid* produces pale-yellow needles [115°] (M. a. K.).—13. The hydrochloride heated with MeOH at 250°–300° gives rise to di-methyl-toluidine, xylidine $C_6H_3Me_2(NH_2)$ [4:3:1] and mesidine (Limpach, *B.* 21, 640).—14. *Cyanogen* passed into an alcoholic solution forms crystalline $C_{16}H_{16}N_4$, which yields $B''H_2Cl_2$ and $B''2HNO_3$ (Bladin, *Bl.* [2] 41, 128).—15. On heating with S it yields $C_{14}H_{12}N_2S$ [120°] crystallising from alcohol in yellow plates and yielding a dibromide $C_{14}H_{10}Br_2N_2S$ [190°] (Gattermann, *B.* 22, 425).—16. $ClSO_3H$ in $CHCl_3$ forms $C_7H_7NH.SO_3H$, which yields BaA'_2 2aq. Both the acid and its salts reproduce o-toluidine when treated with hot water (Traube, *B.* 23, 1656).

Salts (Beilstein a. Kuhlberg, *A.* 156, 66; Rosenstiehl).—B'HCl aq. S. 37·4 at 15·5°. S. (alcohol) 100.—$B'_2H_2PtCl_6$. Decomposed by boiling water (difference from p-toluidine) (De Coninck, *Bl.* [2] 45, 131).—$B'_2H_2ZnCl_4$. White tables (Bibanoff, *Monit. scient.* [3] 4, 925).—B'_2ZnCl_2 2aq (Lachovitch, *M.* 9, 513).—B'_2HgCl_2. [115°]. Prepared by shaking an alcoholic solution of the base with $HgCl_2$ (Klein, *B.* 11, 743). Crystalline powder, sol. alcohol and ether.—B'_2MnCl_2.—$B'_2H_2CuCl_4$. Yellow crystalline pp. got by adding $CuCl_2$ to a solution of the hydrochloride (Pomey, *C. R.* 104, 365).—B'HBr. Trimetric prisms.—B'_2HgBr_2. [101°]. Leaflets (Klein, *B.* 13, 835).—B'_2ZnBr_2 (Leeds, *J.* 1882, 503).—B'HI. Trimetric prisms (Städel, *B.* 16, 28).—B'_2HgI_2. White needles.—B'_2ZnI_2.—B'_2CdI_2.—B'_2HgCy_2.—$B'_4H_4FeCy_6$: crystals.—$B'_2H_2Cu_2(SO_3)_2$. Formed by adding aqueous cupric sulphate and $NaHSO_3$ to a solution of the base in acetic acid (Denigès, *C. R.* 112, 870).—$B'HgH_2(SO_3)_2$ aq.—$B'H_2SO_4$. Crystals (Wellington a. Tollens, *B.* 18, 3313).—$B'_2H_2SO_4$. S. 7·8 at 22°. S. (89 p.c. alcohol) 1·6 at 21·5°.—$B'HNO_3$. S. 10 at 19°. S. (89 p.c. alcohol) 23·5 at 16·5°.—$B'H_3PO_4$. Crystals, v. sol. water (Lewy, *B.* 19, 1717). The salts $B'_2H_3PO_4$ and $B'_3H_3PO_4$ could not be prepared. Aniline sets free o-toluidine from $B'H_3PO_4$. p-Toluidine also sets free o-toluidine from its phosphate.—$B'HSCyCr(SCy)_2 2NH_3$. Red plates, v. sol. hot water (Christensen, *J. pr.* [2] 45, 362).—**Oxalate**: small plates. S. 2·38 at 21°. S. (84 p.c.

alcohol) 2·68 at 21°. S. (ether) ·65 at 21°.—**Chloroacetate** $B'C_2H_3ClO_2$. [95°] (Bischoff, *B.* 21, 1257).—(β ?)-**naphtholate** [81°] (Dyson, *C. J.* 43, 470).

Formyl derivative $C_7H_7.NH.CHO$. [58°]. (288°). Plates (Ladenburg, *B.* 10, 1129; Tobias, *B.* 15, 2446). The crystalline polymeride [211°] is v. sol. hot HOAc, nearly insol. ether and cold alcohol.

Thioformyl derivative $C_7H_7.NH.CSH$: [96°]; yellow needles; bitter taste; sol. alcohol and ether, insol. water. Formed by heating the formyl derivative with P_2S_5. It dissolves unaltered in cold aqueous NaOH, and is reprecipitated by an acid. By distillation in vacuo it forms di-tolyl-formamidine $\begin{matrix}C_7H_7.NH\\ C_7H_7.N\end{matrix}\!\!>\!CH$ with evolution of H_2S and CS_2. By heating for 7 hours at 190° under pressure a crystalline compound $C_{16}H_{16}N_2S$ [160°] is formed with evolution of H_2S (Senier, *B.* 18, 2292; *C. J.* 47, 762).

Acetyl derivative $C_7H_7.NHAc$. [109°] (Bedson a. King, *C. J.* 37, 753). (296°). S. ·85 at 19°. Formed from the base and HOAc (Beilstein a. Kuhlberg, *A.* 156, 77; Alt, *A.* 252, 318), or by shaking it with water and Ac_2O (Hinsberg, *B.* 23, 2962). Converted by PCl_5 into the compound $C_7H_7N:CClMe$, which when carefully heated gives a base $C_7H_7N:CMe.CH_2.CCl:NC_7H_7$ [53°], and when treated with excess of *o*-toluidine gives di-tolyl-acetamidine [69°]. Br in HOAc forms $C_6H_3MeBr(NHAc)$ [1:6:2] [157°].

Chloro-acetyl derivative $C_7H_7NH.CO.CH_2Cl$. [112°]. Formed by the action of chloro-acetyl chloride on *o*-toluidine dissolved in benzene (Widman, *J. pr.* [2] 38, 299). Needles (from dilute alcohol). Converted by alcoholic potash into a pyrazine derivative [160°].

Di-chloro-acetyl derivative $C_7H_7NH.CO.CHCl_2$. Needles, volatile with steam (Rügheimer a. Hoffmann, *B.* 18, 2987).

Tri-chloro-acetyl derivative $C_7H_7NH.CO.CCl_3$. [67°]. Formed from hexachloro-acetone and *o*-toluidine (Cloez, *A. Ch.* [6] 9, 215). Needles, sl. sol. cold alcohol.

Bromo-acetyl derivative $C_7H_7.NH.CO.CH_2Br$. [113°]. Formed from *o*-toluidine and bromo-acetyl bromide (Widman, *J. pr.* [2] 38, 298). Needles. Converted by alcoholic potash into $C_{10}H_{18}N_2O_2$ [160°].

Thio-acetyl derivative $C_7H_7.NH.CS.CH_3$. [68°] (Wallach, *B.* 13, 529; 16, 147). Converted by NaOEt and EtBr into oily $C_7H_7N:CMe.SEt$ (262°).

Propionyl derivative $C_7H_7.NH.COEt$. [87°]. (299° at 730 mm.) Formed from *o*-toluidine and propionic acid (Pictet a. Duparc, *B.* 20, 3421). Needles, sl. sol. hot water. Oxidised by $KMnO_4$ to propionyl-*o*-amido-benzoic acid [117°].

a-Bromo-propionyl derivative $C_7H_7.NH.CO.CHBr.CH_3$. [131°]. Needles, insol. ligroïn (Tigerstedt, *B.* 25, 2920).

Benzoyl derivative $C_7H_7.NHBz$. [131°] (Gudeman, *B.* 21, 2553); [143°] (Brückner, *A.* 205, 130). Long broad needles. Yields benzoyl-*o*-amido-toluic acid on oxidation by $KMnO_4$. PCl_5 forms $C_7H_7.N:CCl.C_6H_5$ (Just, *B.* 19, 982).

Oxalyl derivative $C_2O_2(NH.C_7H_7)_2$. [181°]. Plates (from alcohol) (Bladin, *Bl.* [2] 41, 130).

Phthalyl derivative $C_7H_7N:C_2O_2:C_6H_4$. [182°]. (near 360°). Needles, sol. hot HOAc (Fröhlich, *B.* 17, 2679).

Phenacyl derivative $C_7H_7NH.CH_2.CO.C_6H_5$. [89°]. Formed from the base in alcohol and ω-bromo-acetophenone (Bischler, *B.* 25, 2865). Needles. Yields B'HCl and an acetyl derivative [92°].

m-**Toluidine** $C_6H_4Me.NH_2$ [1:3]. (197°) (Beilstein a. Kühlberg, *A.* 156, 83); (201°) (Buchka a. Schachtebeck, *B.* 22, 840); (205°) (Lorenz, *A.* 172, 180; Merz a. Müller, *B.* 20, 548). S.G. 25 ·998. S.N. 128·1. H.C.v. 964,600. H.C.p. 965,600. H.F. 2,900 (Petit, *A. Ch.* [6] 17, 155). Formed by reduction of *m*-nitro-toluene. Obtained also from *p*-toluidine by successive acetylation, nitration, saponification, diazotisation, boiling with alcohol, and reduction (Lorenz, *B.* 7, 448). Formed also by heating *m*-cresol with $ZnBr_2$, ammonia, and NH_4Br at 300° (M. a. M.). Prepared from benzoic aldehyde by nitration, conversion into *m*-nitro-benzylidene chloride and reduction of this body by zinc and HClAq in the cold (Vienne a. Steiner, *Bl.* [2] 35, 428; Widman, *B.* 13, 676; *Bl.* [2] 36, 216; Ehrlich, *B.* 15, 2011; Harz, *B.* 18, 3398). *m*-Toluidine can be shown to exist in commercial toluidine by means of the nitroso- derivative of di-methyl-*m*-toluidine, since *o*- and *p*- di-methyl-toluidines do not give nitroso- derivatives (Wurster a. Riedel, *B.* 12, 1796).

Properties.—Oil. Its solution in $H_2SO_4H_2O$ is coloured yellowish-brown by CrO_3 and blood-red by HNO_3. Its ethereal solution, shaken with water and a little bleaching-powder, is coloured reddish, the aqueous layer being brownish yellow. HNO_3 added to its solution in a mixture of H_2SO_4 and HOAc below 0° forms nitro-toluidine [134°] and some of its isomerides. Cyanogen passed into its alcoholic solution gives the compound $(C_7H_7.NH_2)_2C_2N_2$ [200°] which forms B'_2HCl, B'_22HNO_3, and $B'_22H_2SO_4$ (Clève a. Bladin, *Bl.* [2] 41, 129). Yields (4,2,1)- xylidine when its hydrochloride is heated with MeOH at 200°–300° (Limpach, *B.* 21, 616).

Salts.—B'HCl. S. 96·3 at 12°. S. (94 p.c. alcohol) 61·9 at 9°.—$B'_2H_2PtCl_6$.—$B'HNO_3$. S. 20·1 at 23·5°. S. (94 p.c. alcohol) 46 at 15°.—$B'HBiI_4$ (Kraut, *A.* 210, 323).—$B'_2H_2SO_4$. S. 6·25 at 14°. S. (94 p.c. alcohol) ·41 at 15°.—$B'_4H_4FeCy_6$ (Eisenberg, *A.* 205, 270).—$B'H_2C_2O_4$. Silky needles. S. 2·65 at 13°; S. (94 p.c. alcohol) 1·77 at 15°; S. (ether) ·13 at 15°.—$B'_32H_2C_2O_4$. White plates, S. 1·45 at 15°; S. (94 p.c. alcohol) ·96; S. (ether) ·128 at 15·5°.—$B'_2H_2C_2O_4$ aq. Very unstable.

Formyl derivative $C_7H_7.NH.CHO$. (278° at 724 mm.) (Niementowski, *B.* 20, 1892). Converted by long boiling into $C_7H_7N:CH.NHC_7H_7$ [123°].

Acetyl derivative $C_7H_7.NHAc$. [65°]. (303°). S. ·44 at 13°.

Di-chloro-acetyl derivative $C_7H_7.NH.CO.CHCl_2$. [106°]. Silky plates (Rügheimer a. Hoffmann, *B.* 18, 2988).

Benzoyl derivative $C_7H_7.NHBz$. [125°] (Just, *B.* 19, 983).

Phthalyl derivative $C_7H_7N:C_2O_2:C_6H_4$.

[153°]. Needles, v. sol. HOAc (Fröhlich, *B.* 17, 2679).

p-Toluidine $C_6H_4Me(NH_2)$[1:4]. [45°] (Städeler); [42·8°] (Mills). (198°) (M. a. H.); (206°) (Städeler, *J. pr.* 96, 65). S.G. 1·046. S. ·35 at 11·5°. H.C.p. 958,800. H.C.v. 957,860. H.F. 9,700 (Petit, *C. R.* 107, 266). S.V. 128,700. Formed by reduction of p-nitrotoluene (Muspratt a. Hofmann, *A.* 54, 1; 66, 144; Noad, *A.* 63, 305: Hugo Müller, *Z.* 1864, 161; Sell, *C. J.* 16, 186; *v.* also o-TOLUIDINE). Formed also by heating p-cresol with ammoniacal $ZnCl_2$ (Buch, *B.* 17, 2637; Merz a. Müller, *B.* 20, 545) and by treating methyl-aniline hydrochloride at 350° (Hofmann, *B.* 5, 720). On sulphonating a mixture of o- and p-toluidine the o-toluidine is first attacked and the p-toluidine can then be distilled off.

Properties.—Plates (from ligroïn or dilute alcohol). Its solution in $H_2SO_4H_2O$ is turned yellow by CrO_3 and blue by HNO_3, in the latter case changing to red and finally brown (Rosenstiehl, *Bl.* 10, 200). Bleaching-powder does not colour its solution in water or ether. PbO_2 and HOAc diluted with water or alcohol give a bright red colour (Lauth, *C. R.* 111, 975). When boiled with water, crystals of an efflorescent hydrate separate on cooling (Lewy, *B.* 19, 2728).

Reactions.—1. Oxidised by $KMnO_4$, alkaline K_3FeCy_6, or chromic acid to $C_{21}H_{21}N_3$ or $C_6H_2Me(NC_7H_7)_2(NH_2)$ [1:2:5:4], which may be readily reduced to $C_6H_2Me(NHC_7H_7)_2(NH_2)$ crystallising from alcohol in colourless plates [166°], readily re-oxidised to $C_{21}H_{21}N_3$ (Barsilowsky, *A.* 207, 102, 118; *J. R.* 1887, 132; Perkin, *C. J.* 35, 728; 37, 546; Klinger a. Pitschke, *B.* 17, 2439; Green, *C. J.* 63, 1395). The compound $C_{21}H_{21}N_3$ crystallises from xylene in dark-red plates [227°], dissolving in acids, forming maroon-red liquids, quickly decomposing with separation of p-toluidine. Conc. H_2SO_4 dissolves $C_{21}H_{21}N_3$, forming a greenish-blue liquid which on warming becomes wine-red with production of p-toluidine.—2. Oxidised by CrO_3 and HOAc to toluene-azo-toluene $C_7H_7.N_2.C_7H_7$. — 3. *Nitrous acid* forms $C_7H_7.N_2.NHC_7H_7$. When $NaNO_2$ is added to a solution of the hydrochlorides of o- and p-toluidine, the o-toluidine is first attacked, yielding $C_7H_7.N_2.C_7H_6NH_2$ and can thus be removed when mixed with p-toluidine (Wülfing, *D. P. J.* 263, 260).—4. Substituents usually enter positions 3 and 5 [Me = 1] but when p-toluidine or its acetyl derivative is dissolved in H_2SO_4 (20 pts.) and *nitrated* the compound $C_6H_3Me(NO_2)(NH_2)$ [1:2:4] is formed instead of the (1,3,4)- isomeride (Nölting a. Collin, *B.* 17, 263).—5. *Bromine* in conc. HClAq at 0° forms $C_6H_2Br_2Me(NH_2)$ [5:3:1:4]; but $C_6H_3BrMe(NH_2)$ [2:1:4] is formed in presence of conc. H_2SO_4 (Hafner, *B.* 22, 2538, 2902).—6. ICl forms $C_6H_2I_2Me(NH_2)$ [5:3:1:4] (Michael a. Norton, *B.* 11, 107).—7. *Chlorine* passed into p-toluidine dissolved in H_2SO_4 at 0° forms $C_6H_3MeCl(NH_2)$ [1:3:4] and larger quantities of its (1,2,4)- isomeride. In HClAq (40 p.c.) the chief product is $C_6H_2MeCl_2(NH_2)$ [1:3:5:4] (Hafner).—8. *Cyanogen* passed into an alcoholic solution forms $C_{16}H_{18}N_4$ or $(C_7H_8N)_2C_2N_2$ crystallising in pearly scales [222°-230°] and yielding the crystalline salts $B'_2 2HCl$, $B'_2 2HNO_3$, $B'_2H_2SO_4$ 6aq, and $B'_2H_2C_2O_4$ (Hofmann, *C. J.* 1, 170; *A.* 66, 144; Clève a. Bladin, *Bl.* [2] 41, 125). The mother-liquor contains $C_{24}H_{23}N_5$ [182°] which yields the salts B′HCl 3aq (a red powder) and $B'_2H_2PtCl_6$. The compound $C_{16}H_{18}N_4$ is also formed when p-toluidine is heated with oxalimido-ether at 100° (Vorländer, *B.* 24, 805).—9. *Cyanuric chloride* forms $C_3N_3(NHC_7H_7)_3$ [283°] (Klason, *J. pr.* [2] 33, 294).—10. *Chloro-acetic acid* (½ mol.) forms $C_7H_7NH.CH_2.CO_2H$, while chloro-acetamide forms $C_7H_7NH.CH_2.CO.NH_2$ (P. F Meyer, *B.* 8, 1158). An alcoholic solution of chloro-acetic acid and HCyS yields $C_{10}H_{12}N_2SO_2$ [176°-182°] (Nencki, *J. pr.* [2] 16, 1).—11. *Di-chloro-acetic acid* forms tolylamido-methyl-oxindole.—12. *Chloral* reacts, with formation of $CCl_3.CH(NHC_7H_7)_2$ [115°] (Wallach, *A.* 173, 278). When chloral is warmed with an alcoholic solution of p-toluidine there is also formed $CCl_3.CH(OEt).NHC_7H_7$ [77°].—13. *Aldehyde* forms crystalline $CH_3.CH(NHC_7H_7)_2$ [c. 60°].—14. *Furfuraldehyde* added to a hot alcoholic solution of p-toluidine and its hydrochloride forms brown amorphous $C_{19}H_{22}N_2O_2$, which yields B′HCl and $B'HNO_3$ both crystallising in purple needles (Stenhouse, *A.* 156, 203). 15. Nascent *formic aldehyde* produces a base $C_{17}H_{18}N_2$ [134°] which is converted by nitrous acid with evolution of CO_2 into $C_{16}H_{18}N_4O_2$ [260°-264°] (Tollens, *J. pr.* [2] 36, 225).—16. *Benzoic aldehyde* at 100° reacts, forming $C_6H_5.CH(NHC_7H_7)_2$ [100°] (326° i.V. at 723 mm.), which changes at 160° into an isomeride [120°-125°] and is converted by Br in CS_2 into $C_{14}H_{11}Br_2N$ [160°-165°] (Schiff, *Z.* 1865, 400; Mazzara, *J.* 1880, 566; Pictet, *B.* 19, 1063). In the action of p-toluidine and its hydrochloride on benzoic aldehyde at 120° there is produced $C_{21}H_{16}N_2$ [178°] and $C_6H_5.CH(C_6H_3Me.NH_2)_2$ [186°] (c. 430°), which yield a di-acetyl derivative [218°] and a di-benzoyl derivative [196°] (Ullmann, *J. pr.* [2] 36, 267).—17. *p-Methoxy-benzoic aldehyde* forms $C_6H_4(OMe).CH:(NC_7H_7)$ [92°] (Steinhart, *A.* 241, 332).—18. *p-Methoxy-benzophenone chloride* yields the compound $C_6H_4(OMe).CPh:NC_7H_7$ [96°] Hantzsch a. Kraft, *B.* 21, 3520).—19. An ethereal solution of $C_6H_5.CCl:NSO_2Ph$, obtained from benzene sulphonic anilide and PCl_5, forms the compound $C_6H_5.C(NHC_7H_7):N.SO_2Ph$, which separates in monoclinic crystals; $a:b:c$ = ·650:1:·533; β = 69° 16′, insol. water (Wallach a. Gossmann, *A.* 214, 216).—20. Alcohol, SO_2 and nitrous acid form the sulphazide $C_{14}H_{16}N_2SO_2$ [140°] (Limpricht, *B.* 20, 1241).—21. Heated with persulphocyanic acid it gives p-tolyl-thiobiuret (*B.* 17, 584).—22. On heating with *sulphur* it yields dehydrothiotoluidine and primuline; *v.* PRIMULINE.—23. *Diazobenzene chloride* yields $C_6H_5.N_2.NHC_7H_7$ [85°] which is identical with the product of the action of p-diazotoluene chloride on aniline (Nölting a. Binder, *B.* 20, 3005).—24. *Bromo-propiolic acid* forms di-tolyl-acetamidine $C_{16}H_{18}N_2$ [120°] (Mabery a. Krause, *B.* 22, 3307), which is also formed by the action of HOAc and PCl_3 on p-toluidine (Hofmann, *Pr.* 15, 55).—25. *Itaconic acid* in boiling aqueous solution forms

$C_7H_7.N{<}\genfrac{}{}{0pt}{}{CH_2.CH.CO_2H}{CO\,.\,CH_2}$

[185°] (Scharfenberg, *A.* 254, 150).—26. *Acetyl-citric anhydride* dissolved in chloroform forms

$C_3H_5O(CO_2H)(CO.NHC_7H_7)_2$ [189°] Klingemann, *B.* 22, 987).—27. *Malic acid* at 160° yields $C_2H_4O(CO.NHC_7H_7)_2$ [208°] (Bischoff, *B.* 23, 2045).—28. The hydrochloride heated with MeOH yields $C_6H_3Me_2(NH_2)$ [1:3:4] (Limpach, *B.* 21, 640).—29. *Ethylene oxide* forms oxy-ethyl-*p*-toluidine (Demole, *B.* 7, 635). —30. $SOCl_2$ forms thionyl-toluidine (*q. v.*).—31. $POCl_3$ forms $PO(NHC_7H_7)_3$ [192°], which yields $PO(NHC_7H_6Br)_3$ [180°] and $PO(NH.C_7H_6.NO_2)_3$ [247°] (Rudert, *B.* 26, 569). Another product of the action of $POCl_3$ is $POCl(NHC_7H_7)_2$, whence water forms $HO.PO(NHC_7H_7)_2$ [124°]. — 32. $PSCl_3$ forms $PS(NHC_7H_7)_3$ [135°].

Salts.—$B'HCl$. S. 22·9 at 11°; S. (89 p.c. (alcohol) 25 at 17°.—$B'HAuCl_4$.—$B'_2H_2PtCl_6$. Not decomposed by boiling water (De Coninck, *Bl.* [2] 45, 131).—B'_2PtCl_2 (Gordon, *B.* 3, 177; Cochin, *Bl.* [2] 31, 499).—$B'_2H_2PtCy_4$ (Scholz, *M.* 1, 905).—$B'PtCl_2Et_3PO_3$ (Saillard, *Bl.* [2] 18, 111). — $B'_2PtCl_2Me_3PO_3$. — $B'PtCl_22Et_3PO_3$ (Cochin, *J.* 1878, 315).—$B'_2ZnCl_2$3aq (Lachovitch, *M.* 9, 513).—$B'_2H_2ZnCl_4$ (Gräfinghoff, *Z.* 1865, 599).—B'_2HgCl_2. [125°]. Thick needles, sol. alcohol and ether (Klein, *B.* 11, 743).—B'_2NiCl_22EtOH. Green pp. (Lippmann a. Vortmann, *B.* 12, 81).—B'_2CoCl_2. Blue needles.—$B'_2H_2SnCl_6$. Monoclinic crystals (Hjortdahl, *J.* 1882, 535).—$B'_2H_2CuCl_4$ (Pomey, *C. R.* 104, [illegible]00).—B'_2MnCl_2 (Leeds, *J.* 1882, 503).—$B'_2UrO_2Cl_2$.—$B'HBr$. Plates (Städel, *B.* 16, 28).—B'_2HgBr_2. [121°]. Plates (Klein, *B.* 13, 835). — B'_2ZnBr_2. — B'_2CdBr_2.—$B'HI$.—B'_2HgI_2. [81°]. — $B'HBiI_4$ (Kraut, *A.* 210, 324). — $B'_6(H_2SO_4)_3HI_5$ (Jörgensen, *J. pr.* [2] 14, 386).—B'_2ZnI_2.—B'_2CdI_2.—$B'HNO_3$. S. 17·7 at 23·5°; S. (89 p.c. alcohol) 42 at 20°. B'_2AgNO_3. Crystals, converted into $B'_2H_2SO_4$ by water (Tollens, *B.* 18, 3312).—$B'_4Ag_2SO_4$ 2aq (Mixter).—$B'H_3PO_4$. Thick needles, v. sl. sol. cold water (Lewy, *B.* 19, 1717).—$B'_2(NH_2Ph)H_4CoCy_6$ 1½aq (Weselsky, *J.* 1869, 314).—$B'_3H_3CoCy_6$ 2aq. B'_2HgCy_2.—$B'HCr(SCy)_42NH_3$. Plates (Christensen, *J. pr.* [2] 45, 362).—$B'_2Cu_2H_2(SO_3)_2$. Yellowish-white hexagonal plates.—$B'HgH_2(SO_4)_2$aq (Denigès, *C. R.* 112, 870).—**Oxalate** $B'H_2C_2O_4$ ½aq (Bornemann, *B.* 22, 2710). S. ·87 at 14°; S. (84 p.c. alcohol) ·48 at 22°. Insol. ether.—**Chloroacetates** $B'C_2H_3ClO_2$ [102°] (Baralis, *J.* 1884, 698).—$B'C_2H_2Cl_2O_2$. [141°]. (B.) [136°] (Duisberg, *B.* 18, 194).—$B'C_2HCl_3O_2$. [137°].—**Tri-chloro-lactate** $B'C_3H_3Cl_3O_3$. [135°].—**Mucate** $B'_2C_6H_{10}O_8$. Yellowish crystals, sol. hot water. —**Picrate** $B'C_6H_3N_3O_7$. [169°] (Smolka, *M.* 6, 923). S. ·54 at 18·5°; S. (95 p.c. alcohol) 4·29 at 18°.—**Phenate** [31·1°]. Got by heating *p*-toluidine with phenol (Dyson, *C. J.* 43, 468). Needles (from ligroïn).—**Compound with picramide** $B'C_6H_2(NO_2)_3NH_2$. Black needles with green reflex (Mertens, *B.* 11, 843).

Formyl derivative $C_7H_7.NH.CHO$. [45°] (Hübner a. Rudolph, *A.* 209, 371); [52°] (Tobias, *B.* 15, 2446); [53°] (Bamberger a. Wulz, *B.* 24, 2080). Formed by boiling *p*-toluidine with formic acid or, together with the **oxalyl derivative** $C_2O_2(NHC_7H_7)_2$ [263°], by heating *p*-toluidine oxalate. Prisms. Converted by heating with P_2S_5 into $C_7H_7.NH.CHS$ [174°] (Senier, *B.* 18, 2294; *C. J.* 47, 766). Yields $C_7H_7.NNa.CHO$ aq.

Acetyl derivative $C_7H_7.NHAc$. [147°] (Hübner a. Wallach, *A.* 154, 302; Kelbe, *C. J.* 44, 915). (307°) (Beilstein a. Kuhlberg, *A.* 156, 74). S. ·089 at 22°. Dimorphous, crystallising in monoclinic forms; $a:b:c = 1·216:1:·788$; $\beta = 106° 7'$, and also in trimetric crystals; $a:b:c = ·651:1:·329$ (Panebianco, *G.* 9, 362). Oxidised by $KMnO_4$ to acetyl-*p*-amido-benzoic acid (Hofmann, *B.* 9, 1299). Oxidised in like manner in the animal body (Jaffe a. Hilbert, *H.* 12, 295). PCl_5 forms a liquid product which solidifies when strongly cooled, the crystals doubtless being $C_7H_7NH.CCl_2.CH_3$. This readily splits up into HCl and $C_7H_7.N:CCl.CH_3$. This is a colourless solid which is converted by Aq into acetyl-*p*-toluidine; by toluidine into di-tolyl-acetamidine. The chloro-imide $C_7H_7.N:CCl.CH_3$ at 100° forms a base $C_{18}H_{19}N_2Cl$ [72°], which may be crystallised from alcohol. It is probably $C_7H_7N:CMe.CH_2.CCl:NC_7H_7$. It is decomposed by moist air or water with production of $MeC(NC_7H_7)NC_7H_7H$, HOAc and $MeCONHC_7H_7$, and by heat with production of an amorphous base $C_{18}H_{18}N_2$ (Wallach a. Fassbender, *A.* 214, 202). Nitrous acid converts acetyl-*p*-toluidine into $C_7H_7.NAc.NO$ [80°] (O. Fischer, *B.* 10, 959).

Chloro-acetyl derivative $C_7H_7NH.CO.CH_2Cl$. [162°]. Needles (Tommasi, *Bl.* [2] 19, 400; Meyer, *B.* 8, 1154).

Di-chloro-acetyl derivative $C_7H_7NH.CO.CHCl_2$. [153°] (Rügheimer a. Hoffmann, *B.* 18, 2980).

Tri-chloro-acetyl derivative $C_7H_7NH.CO.CCl_3$. [80°] (C.); [102°] (J.). S. (alcohol) 12·5 at 14°. Formed from *p*-toluidine and $(CCl_3)_2CO$ (Cloez, *A. Ch.* [6] 9, 145), and also from *p*-toluidine and $CCl_3.COCl$ (Judson, *B.* 3, 784).

Bromo-acetyl derivative $C_7H_7NH.CO.CH_2Br$. [164°]. Needles (Abenius, *J. pr.* [2] 40, 433) converted by alcoholic potash into an azine and $C_7H_7NH.CO.CH_2.OEt$ [32°] which is v. e. sol. alcohol.

Thio-acetyl derivative $C_7H_7.NH.CS.CH_3$. [131°]. Formed from the acetyl derivative and P_2S_5 (Jacobsen a. Ney, *B.* 22, 906). Got also by heating tolyl-acetamidine with CS_2 at 100°, or di-tolyl-acetamidine with H_2S (Bernthsen a. Trompetter, *B.* 11, 1759; Wallach a. Pannes, *B.* 13, 529). Converted by NaOEt and EtBr into oily $C_7H_7N:CMe.SEt$ (272°) (Wallach a. Wüsten, *B.* 16, 147).

a-Bromo-propionyl derivative $C_7H_7NH.CO.CHBr.CH_3$. [125°] (Tigerstedt, *B.* 25, 2921). Plates, v. sol. $CHCl_3$.

Benzoyl derivative C_7H_7NHBz. [158°]. (232°). Formed from *p*-toluidine and BzCl (Jaillard, *Z.* 1865, 440; Kelbe, *B.* 8, 875; Hübner, *A.* 208, 310; Wallach, *A.* 214, 217; Gudeman, *B.* 21, 2553; Müller, *B.* 22, 2404). Needles, v. sol. alcohol. Converted by PCl_5 into $C_7H_7N:CCl.C_6H_5$ [52°] (Just, *B.* 19, 980) crystallising from ligroïn in prisms.

p-Nitro-benzoyl derivative $C_6H_4(NO_2).CO.NHC_7H_7$. [197°]. Formed from *p*-toluidine and *p*-nitro-benzoyl chloride. Yellow needles (Gattermann, *B.* 25, 1082). Converted by PCl_5 into $C_6H_4(NO_2).CCl_2.NHC_7H_7$ [119°] crystallising in golden prisms.

Phenacyl derivative $C_7H_7NH.CH_2.CO.C_6H_5$. [127°]. Formed from ω-bromo-acetophenone and *p*-toluidine in alcohol (Bischler, *B.* 25, 2866). Yellow prisms, yielding B'HCl and an acetyl derivative [89°] crystallising in white needles (from alcohol).

Phthalyl derivative $C_7H_7N{:}C_2O_2{:}C_6H_4$. [205°] (Fröhlich, *B.* 17, 2679).

References.—BROMO-, DIBROMO-IODO-, BROMO-NITRO-, CHLORO-, TRI-CHLORO-NITRO-, IODO-, NITRO-, and NITROSO- TOLUIDINES.

TOLUIDINE SULPHONIC ACID *v.* AMIDO-TOLUENE SULPHONIC ACID and also NITRO- and IODO- TOLUIDINE SULPHONIC ACID.

TOLUIDINE THIOSULPHONIC ACID *v.* AMIDO-TOLUENE THIOSULPHONIC ACID.

TOLU-(αβ)-NAPHTHAZINE $C_{17}H_{12}N_2$ *i.e.*

$$C_6H_4\left<\begin{array}{l}CH{:}CH.C.N\\ \text{------}\ \ \ C.N\end{array}\right>C_6H_3Me\quad\left[\begin{array}{cc}3&\\&1\\4&\end{array}\right]$$

[180°]. Formed by oxidation of a mixture of tolylene-*o*-diamine (1 mol.) and (β)-naphthol (1 mol.) with K_3FeCy_6. Formed also, together with the isomeride [169°], by the action of (β)-naphthoquinone on tolylene-*o*-diamine (Witt, *B.* 20, 577). Dissolves in conc. H_2SO_4 with violet-red colour. Forms with its isomeride a molecular compound [142°].

Tolu-(αβ)-naphthazine $C_{17}H_{12}N_2$ *i.e.*

$$C_6H_4\left<\begin{array}{l}CH{:}CH.C.N\\ \text{------}\ \ \ C.N\end{array}\right>C_6H_3Me\quad\left[\begin{array}{cc}4&\\&1\\3&\end{array}\right]$$

[169°]. Formed as above, and also, together with amido-benzene *p*-sulphonic acid, by boiling sulpho-benzene-azo-(β)-naphthyl-*p*-tolyl-amine with dilute H_2SO_4, and by boiling 'wool black' $C_6H_4(SO_3H).N_2.C_6H_3(SO_3H).N_2.C_{10}H_5.NHC_7H_7$ with dilute H_2SO_4 (Witt, *B.* 20, 577). Yellow crystals, v. sl. sol. alcohol. Conc. H_2SO_4 forms a brownish-red solution.

TOLUNITRANILIC ACID *v.* NITRO-DI-OXY-TOLUQUINONE.

TOLUOÏN *v.* DI-METHYL-BENZOÏN.

TOLUOL *v.* TOLUENE.

TOLUPHOSPHINIC ACID *v.* PHOSPHOTOLUIC ACID.

TOLUQUINOL *v.* HYDROTOLUQUINONE.

TOLUQUINOLINE *v.* METHYL-QUINOLINE.

TOLUQUINONE $C_7H_6O_2$ *i.e.* $C_6H_3MeO_2$ [2:4:1]. [69°].

Formation.—1. By oxidation of tolylene-*p*-diamine or of *o*-toluidine (Nietzki, *B.* 10, 832, 1934; *A.* 215, 158; Ladenburg, *B.* 10, 1128).—2. By boiling crude creosol with MnO_2 and dilute H_2SO_4 (Carstanjen, *J. pr.* [2] 23, 425). Separated from accompanying xyloquinone by reduction with SO_2, crystallising the hydrotoluquinone from benzene, and re-oxidising by fuming HNO_3.—3. By oxidation of *m*-xylidine (Nölting a. Baumann, *B.* 18, 1151).

Preparation.—20 g. of *o*-toluidine are dissolved in 600 c.c. of water containing 160 g. of H_2SO_4; 20 g. of finely powdered potassium bichromate are added by degrees, with continual agitation, keeping the temperature at 10°–15°. After standing over night, 33 g. more $K_2Cr_2O_7$ are added; the quinone is then extracted with ether, dried over $CaCl_2$, and the ether removed by distillation. The yield is about 86 p.c. of the theoretical quantity (Schniter, *B.* 20, 2283).

Properties.—Golden-yellow plates smelling like quinone. Very volatile. M. sol. hot water, v. sol. alcohol and ether. Its aqueous solution is turned brown by alkalis. SO_2 reduces it to hydrotoluquinone. Dilute (50 p.c.) H_2SO_4 changes it to isotoluquinone $(C_7H_6O_2)_x$, a powder not melted at 300° (Spica, *G.* 12, 225). An aqueous solution of toluquinone mixed with one of hydrotoluquinone deposits steel-blue needles of the quinhydrone [52°], v. e. sol. water. *o*-Nitroaniline forms [2:4:4:6] $C_6H_3MeO_2.NH.C_6H_4NO_2$ crystallising from alcohol in red crystals decomposing at 200° (Leicester, *B.* 23, 2796). Nitro-*p*-toluidine $C_6H_3Me(NO_2).NH_2$ [1:3:4] forms a homologous body.

Chlorimide

$$C_6H_3Me\left<\begin{array}{l}O\\ NCl\end{array}\right.\left[\begin{array}{cc}&3\\1&\\&2\end{array}\right]$$

[88°] (Hirsch, *B.* 18, 1514). Formed by the action of a solution of bleaching-powder on the hydrochloride of amido-*o*-cresol. Yellow prisms (from alcohol) volatile with steam. Decomposes violently at 100°-115°. By digestion with $NaHSO_3$ for several hours it is converted into amido-cresol sulphonic acid.

Chlorimide

$$C_6H_3Me\left<\begin{array}{l}NCl\\ O\end{array}\right.\left[\begin{array}{cc}&5\\1&\\&2\end{array}\right]$$

[75°]. Made in like manner from amido-*m*-cresol (Staedel, *A.* 259, 218). Yellow prisms (from alcohol), volatile with steam.

Oxim $C_6H_3MeO(NOH)$ [2:1:4]. *Nitroso-o-cresol.* [135°]. Formed by the action of nitrous acid on *o*-cresol (Nölting a. Kohn, *B.* 17, 370). Formed also by the action of hydroxylamine hydrochloride on toluquinone (Goldschmidt a. Schmid, *B.* 17, 2063). Needles (from water), decomposed by fusion. V. sol. alcohol and ether. Yields nitro-cresol [95°] on oxidation. NaA'3aq. — KA': brown needles, v. sol. water.

Oxim $C_6H_3MeO(NOH)$ [2:4:1]. *Nitroso-m-cresol.* Formed by boiling nitroso-di-methyl-*m*-toluidine with dilute (10 p.c.) NaOHAq (Wurster a. Riedel, *B.* 12, 1799). Formed also by the action of $NO_2.SO_4H$ on *m*-cresol and water at 0° (Bertoni, *G.* 12, 303). Small needles (from water). Decomposes at 145°-150°. Sl. sol. hot water. Gives Liebermann's reaction. Forms an acetyl derivative $C_6H_3MeO(NOAc)$ [92°] crystallising in large prisms.

Di-oxim $C_6H_3Me(NOH)_2$ [2:1:4]. Formed by the action of hydroxylamine on either mono-oxim (Nietzki a. Guitermann, *B.* 21, 430) or by boiling nitroso-*o*- or *m*-toluidine with hydroxylamine hydrochloride (Mehne, *B.* 21, 729). Yellow needles, exploding at 220°-234°, v. sl. sol. benzene, sol. hot water, alcohol, and ether. Reduced by tin and HClAq to tolylene-*p*-diamine. Alkaline K_3FeCy_6 forms di-nitroso-toluene. Ac_2O forms $C_6H_3Me(NOAc)_2$ [120°], crystallising from alcohol in colourless needles.

Ditolylimide $C_6H_3Me(NC_7H_7)_2$. [146°]. Formed by oxidation of tolylene-di-tolyl-diamine in alkaline solution (Green, *C. J.* 63, 1409). Red prisms, v. sol. alcohol, v. e. sol. benzene.

References.—DI-BROMO-, CHLORO-, IODO-, and OXY- TOLUQUINONE.

TOLUQUINOXALINE *v.* METHYL-QUINOXALINE.

***o*-TOLURIC ACID** $C_{10}H_{11}NO_3$ *i.e.* $C_7H_7.CO.NH.CH_2.CO_2H$. *Toluyl-glycocoll*

[162·5°]. Formed from toluyl chloride, amido-acetic acid, and NaOH (Gleditsch a. Möller, *A.* 250, 376). Found in the urine of dogs that have taken *o*-toluic acid. Thick plates, sol. water.

m-**Toluric acid.** [139°]. Formed as above, and also when *m*-xylene or *m*-toluic acid is administered to a dog (G. a. M.; *cf.* Schultzen a. Naunyn, *Z.* 1868, 29). M. sol. water.—$ZnA'_2$4aq.—$CuA'_2$6aq.

p-**Toluric acid.** [161°]. Formed from *p*-toluyl chloride and glycocoll (G. a. M.) and also by passage of *p*-xylene or *p*-toluic acid through the animal body (Kraut, *A.* 98, 360). Plates (from water), sl. sol. cold water, v. sol. alcohol.—$CaA'_2$3aq.—$BaA'_2$5aq.—AgA'.

TOLUYL. The radicle $CH_3.C_6H_4.CO$. The same name has been given to the radicle $CH_3.C_6H_4.CH_2$, which is isomeric with xylyl, and has also been called tolyl, but may be more conveniently named methyl-benzyl. Tolyl is $CH_3.C_6H_4$.

o-**TOLUYL-ACETIC ACID**

Ethyl ether $C_6H_4Me.CO.CH_2.CO_2Et$. Oil, got by boiling the nitrile with alcohol and HCl. Gives a violet colour with $FeCl_3$.

Nitrile $C_7H_7.CO.CH_2.CN$. [74·4°]. Formed by boiling *o*-toluyl-cyano-acetic ether with water (Haller, *C. R.* 108, 1117). Prisms, sol. alcohol and alkalis. Diazobenzene chloride and NaOH form $C_7H_7.CO.CHCy.N_2.C_6H_5$ [125°]. Cold alcoholic HCl forms the hydrochloride of $C_7H_7.CO.CH_2.C(NH).OEt$ [116°].

TOLUYL-ACRYLIC ACID $C_{11}H_{10}O_3$ *i.e.* $C_6H_4(CH_3).CO.CH:CH.CO_2H$. [138°]. Formed by the action of $AlCl_3$ on a mixture of maleic anhydride and toluene (Pechmann, *B.* 15, 888).

TOLUYL ALCOHOL *v.* Tolyl-carbinol.

TOLUYLAMIDE *v. Amide* of Toluic acid.

p-**TOLUYL-*o*-BENZOIC ACID** $C_{15}H_{12}O_3$ *i.e.* [1:4] $C_6H_4Me.CO.C_6H_4.CO_2H$ [1:2]. *Phenyl tolyl ketone carboxylic acid.* Mol. w. 240. [146°]. Formed by the action of phthalic anhydride on toluene in presence of $AlCl_3$ (Friedel a. Crafts, *A. Ch.* [6] 14, 447; *C. R.* 92, 833). Prisms (containing aq) (from alcohol-toluene), v. sl. sol. hot water. Its dilute aqueous solution tastes sweet. Potash-fusion yields benzoic and *p*-toluic acids. Warm conc. H_2SO_4 forms (*β*)-methyl-anthraquinone. — BaA'_2 4aq. — CdA'_2 ½aq. — CuA'_2 4aq.

Methyl ether MeA'. [53°].

Ethyl ether EtA'. [69°].

Toluyl-benzoic acid $C_7H_7.CO.C_6H_4.CO_2H$. [222°]. Formed by oxidation of di-tolyl-methane and of *u*-di-tolyl-ethane (Weiler, *B.* 7, 1184; Ador a. Crafts, *C. R.* 85, 1163; O. Fischer, *B.* 7, 1195; Anschütz, *A.* 235, 316). Slender needles (from MeOH), sl. sol. hot water.—KA': tufts of long needles.—AgA'.

Reference.—Di-chloro-tolyl-benzoic acid.

TOLUYLENE- *v.* Tolylene-.

p-**TOLUYL-PROPIONIC ACID** $C_{11}H_{12}O_3$ *i.e.* $C_7H_7.CO.CH_2.CH_2.CO_2H$. [127°] (C.); [120°] (B.). Formed by the action of succinyl chloride or succinic anhydride on toluene and $AlCl_3$ (Claus, *B.* 20, 1378; Burcker, *Bl.* [2] 49, 448). Plates or needles (from water), v. sol. ether.—BaA'_2 4aq: sol. hot water.—AgA': small needles, insol. Aq.

ω-**TOLUYL-TOLUIC ACID.** *Lactone*

$C_6H_4<\begin{matrix}CH:C.C_7H_7\\CO\ \ O\end{matrix}$. [93°]. Got from nitro-tolyl-methylene-phthalide, HIAq, and P (Heilmann, *B.* 23, 3166). Thin prisms. Converted by alcoholic NH_3 into

$C_6H_4<\begin{matrix}CH:C.C_7H_7\\CO.NH\end{matrix}$ [196°].

oo-**DITOLYL** $C_{14}H_{14}$ *i.e.* [1:2] $C_6H_4Me.C_6H_4Me$ [1:2]. Mol. w. 182. (272°). S.G. $\frac{10.5}{}$ ·9945. Formed from *o*-bromo-toluene and Na (Fittig, *A.* 139, 178). Liquid.

mm-**ditolyl** [1:3] $C_6H_4Me.C_6H_4Me$ [1:3]. (280°) (Schultz, *B.* 17, 468); (288°) (Perrier, *C. R.* 114, 484); (289°) (Stolle, *B.* 21, 1096). S.G. $\frac{16}{4}$ ·9993. Formed by diazotising di-amido-*o*-ditolyl and boiling the product with alcohol. Formed also by the action of Na on *m*-bromo-toluene (P.), and by reduction of di-oxy-*m*-ditolyl and di-chloro-*m*-ditolyl. Oil; yields diphenyl di-*m*-carboxylic acid and isophthalic acid on oxidation.

pp-**ditolyl** [1:4] $C_6H_4Me.C_6H_4Me$ [1:4]. [121°]. S.V. 198·0. Formed by adding Na to a solution of *p*-bromo-toluene in toluene (Zincke, *B.* 4, 396; Louguinine, *B.* 4, 514). Monoclinic prisms (from ether). Yields on oxidation *p*-tolyl-benzoic acid [244°] and diphenyl di-*p*-carboxylic acid (Carnelley, *C. J.* 32, 653). $SbCl_5$ at 360° forms CCl_4 and per-chloro-diphenyl.

om-**Ditolyl** [1:2] $C_6H_4Me.C_6H_4Me$ [1:3]. (270°). Formed from [2:4:1] $C_6H_3Me(NH_2).C_6H_3Me(NH_2)$ [1:3:4] by elimination of amidogen by the diazo-reaction (Schultz, *B.* 17, 471). Yields isophthalic acid on oxidation by CrO_3.

op-**Ditolyl** [1:2] $C_6H_4Me.C_6H_4Me$ [1:4]. (272°-280°). Formed from crude bromo-toluene and Na. It is also one of the products of the passage of a mixture of benzene and toluene through a red-hot tube (Carnelley, *C. J.* 37, 707; 47, 587). Oxidised by CrO_3 and HOAc to *o*-tolyl-*p*-benzoic acid [180°] and terephthalic acid.

Ditolyls have also been obtained by Barbier (*C. R.* 78, 1769) and Varet a. Vienne, *Bl.* [2] **47,** 919).

References.—Di-amido-, Di-bromo-, Di-iodo-, Nitro-amido-, Oxy-amido-, and Oxy-ditolyl.

p-**TOLYL-ACETAMIDINE** $C_9H_{12}N_2$ *i.e.* $CH_3.C(NH).NHC_6H_4Me$ [1:4]. [96°]. Formed from *p*-toluidine hydrochloride and acetonitrile (Bernthsen a. Trompetter, *B.* 11, 1757). Prisms. Alkaline in reaction.—$B''_2H_2PtCl_6$.—$B''H_2C_2O_4$. Prisms, v. sol. water and alcohol.

Di-*o*-tolyl-acetamidine

[1:2] $C_6H_4Me.NH.CMe:NC_6H_4Me$ [1:2]. [136°] (W.); [140°] (L.). Formed by the action of PCl_3 on *o*-toluidine and HOAc (Ladenburg, *B.* 10, 1262), and also by the action of *o*-toluidine on $CMe(SEt):NC_7H_7$ or on $CMeCl:NC_7H_7$ (Wallach a. Wüsten, *B.* 16, 148; *A.* 214, 208). Needles.

Di-*p*-tolyl-acetamidine

[1:4] $C_6H_4Me.NH.CMe:N.C_6H_4Me$ [1:4]. *Acet-tolyl-imid-tolyl-amide.* [120°]. Formed from *p*-toluidine and $CMeCl:NC_7H_7$, which is the product of the action of PCl_5 on acetyl-*p*-toluidine (Wallach a. Fassbender, *A.* 214, 203; *B.* 9, 1214; 16, 148). Formed also from *p*-toluidine and bromopropiolic acid (Mabery a. Krause, *B.* 22, 3307). Prisms (from benzene). Formed also from *p*-toluidine, HOAc, and PCl_3.—$B'_2H_2PtCl_6$.—B'HCl. [200°].

op-**Di-tolyl-acetamidine**

$C_6H_4Me.NH.CMe:NC_6H_4Me$. [142°]. Formed from *o*-toluidine and the product of the action of PCl_5 on acetyl-*p*-toluidine, and also from

p-toluidine and the product of the action of PCl_5 on acetyl-o-toluidine (Wallach a. Pannes, *A.* 214, 209). Formed also from p-toluidine and [1:2] $C_6H_4MeN{:}CMe.SEt$, and from o-toluidine and [1:4] $C_6H_4MeN{:}CMeSEt$; the compounds obtained, [143°] and [140°] respectively, being perhaps isomeric and not identical (Wallach, *B.* 16, 148).

o-**TOLYL-ACETIC ACID** $C_9H_{10}O_2$ *i.e.* [1:2] $C_6H_4Me.CH_2.CO_2H$. [89°]. Formed by saponification of its nitrile (Radziszewski a. Wispeck, *B.* 15, 1747; 18, 1281). Needles, sl. sol. cold water. Yields phthalic acid on oxidation.—CaA'_2 4aq.—AgA'. Plates, sol. hot water

Amide [161°]. Plates, sl. sol. ether.

Nitrile C_9H_9N. (244°). S.G. ^{22} 1·0156. Formed from ω-bromo-o-xylene and KCy. Oil.

m-**Tolyl-acetic acid** [1:3] $C_6H_4Me.CH_2.CO_2H$. [61°]. Formed by saponifying its nitrile, which is obtained from ω-bromo-m-xylene (R. a. W.). Needles, sol. hot water.—CaA'_2 3aq.—AgA'.

Amide [141°]. Sl. sol. cold water.

Nitrile (241°). S.G. ^{22} 1·0022. Oil.

Methyl ether MeA'. (228°). S.G. $^{17.5}$ 1·041. Liquid (Senkowski, *M.* 9, 854).

Ethyl ether EtA'. (238°). S.G. $^{17.5}$ 1·018.

p-**Tolyl-acetic acid** [1:4] $C_6H_4Me.CH_2.CO_2H$. [94°]. Formed in like manner from ω-bromo-p-xylene (R. a. W.; Strassmann, *B.* 22, 1230). Got also by reducing p-tolyl-glyoxylic acid with HI (Claus a. Kroseberg, *B.* 20, 2051). Needles, sl. sol. cold water. Phthalic anhydride and NaOAc yield $C_6H_4\left\langle\begin{matrix}CO\text{———————}\\C(CH.C_6H_4Me)\end{matrix}\right\rangle O$ [151°], whence HNO_2 at 0° forms the compound $C_6H_4\left\langle\begin{matrix}CO\text{———————}\\C(NO_2).CH(NO_2)C_7H_7\end{matrix}\right\rangle O$ [140°], which is converted by treatment with boiling alcohol into $C_6H_4\left\langle\begin{matrix}CO\text{—————}\\C(CNO_2)C_7H_7\end{matrix}\right\rangle O$ [207°], and is reduced by HI and P to $C_6H_4\left\langle\begin{matrix}CH{:}C.C_7H_7\\CO\ .O\end{matrix}\right.$ [116°] (Ruhemann, *B.* 24, 3965).—NaA': needles, sol. water.—CaA'_2 3aq.—AgA': needles, sol. hot water.

Ethyl ether EtA'. (240°).

Amide $C_9H_{11}NO$. [185°]. Plates. Formed from the acid, and also by the action of yellow ammonium sulphide on p-tolyl methyl ketone (Willgerodt, *B.* 21, 534).

Nitrile $C_8H_9.CN$. [18°]. (243°). S.G. ^{22} ·9922.

Reference.—*Nitro-* and *Oxy-*TOLYL-ACETIC ACID.

m-**TOLYL-ACETYLENE** [1:3] $C_6H_4Me.C{:}CH$. *Methyl-styrene.* (164°). Formed by distilling barium m-tolyl-propiolate with lime (Müller, *B.* 20, 1215). Formed also by saturating a solution of m-tolyl-acrylic acid with HBr at 0° and treating the product with NaOHAq. Oil, becoming solid on standing. Gives an explosive red pp. with ammoniacal Cu_2Cl_2. Br forms $C_7H_7.CHBr.CH_2Br$ [45°].

Di-tolyl-acetylene $C_7H_7.C{:}C.C_7H_7$. [136°]. Formed by heating $C_7H_7.CHBr.CHBr.C_7H_7$ with alcoholic potash at 140° (Goldschmiedt a. Hepp, *B.* 6, 1505). Needles (from alcohol).

DI-TOLYL-ACIPIPERAZINE *v.* OXY-DI-TOLYL-PYRAZINE.

Di-tolyl-di-aci-piperazine *v.* DI-OXY-DI-TOLYL-PYRAZINE.

m-**TOLYL-ACRYLIC ACID** $C_{10}H_{10}O_2$ *i.e.* [1:3] $C_6H_4Me.CH{:}CH.CO_2H$. *Methyl-cinnamic acid.* [111°]. Formed by heating m-toluic aldehyde with Ac_2O and NaOAc (Bornemann, *B.* 17, 1474; 20, 1382; Von Miller, *B.* 20, 1213; 23, 1899). Silky needles, v. sol. alcohol, sl. sol. ligroïn. $FeCl_3$ gives a bright-yellow pp. in neutral solutions. Reduced by sodium-amalgam to m-tolyl-propionic acid [43°]. $KMnO_4$ oxidises it to m-toluic acid. Br forms $C_7H_7.C_2H_2Br_2.CO_2H$ [167°].—BaA'_2—AgA'. Crystalline powder.

p-**Tolyl-acrylic acid** [1:4] $C_6H_4Me.CH{:}CH.CO_2H$. [197°]. Formed from p-toluic aldehyde, NaOAc, and Ac_2O (Von Miller, *B.* 23, 1897; *cf.* Kröber, *B.* 23, 1033). Needles (from benzene), sl. sol. hot water. Reduced by HI and P to p-tolyl-propionic acid. Br forms $C_6H_4Me.CHBr.CHBr.CO_2H$.

TOLYL ALCOHOL *v.* TOLYL-CARBINOL.

p-**TOLYL-ALLYL-HYDRAZINE** $C_{10}H_{14}N_2$ *i.e.* $C_7H_7N(C_3H_5).NH_2$. (160°–170° at 90 mm.). Got from tolyl-hydrazine and allyl bromide (Michaelis, *B.* 26, 2178). Oil. Yields $B'HCl$. [129°]. Benzoic aldehyde forms the compound $C_7H_7.N(C_3H_5).N{:}CHPh$ [61°], while cinnamic aldehyde forms the corresponding hydrazide [118°]. Ferric chloride gives the tetrazone $(C_7H_7(C_3H_5)N)_2N_2$ [104°].

o-**TOLYL-ALLYL-THIO-SEMI-CARBAZIDE** $C_7H_7NH.NH.CS.NHC_3H_5$. [105°]. Formed by warming o-tolyl-hydrazine with allyl thiocarbimide (Avenarius, *B.* 24, 268). Needles, insol. water, v. sol. alcohol and CS_2.

p-**Tolyl-allyl-thio-semi-carbazide** [128°]. Formed in like manner (A.). Needles.

o-**TOLYL-ALLYL-THIO-UREA** $C_{11}H_{14}N_2S$ *i.e.* $C_7H_7NH.CS.NHC_3H_5$. *Tolyl-thiosinamine.* [98°]. Formed from o-toluidine and oil of mustard (Jaillard, *Z.* 1865, 441; Maly, *Z.* [2] 5, 258; Weith, *B.* 8, 1528; Prager, *B.* 22, 2998). Pearly crystals, m. sol. ether, v. sol. HOAc. According to Dixon (*C. J.* 55, 622), it melts at 76°. Converted by heating with HClAq into tolyl-propylene-ψ-thio-urea [126°]. Cyanogen passed into its alcoholic solution forms $C_{13}H_{14}N_4S$, which on warming with dilute H_2SO_4 and alcohol gives a pp. of oxalyl-tolyl-allyl-thio-urea $CS\left\langle\begin{matrix}NC_7H_7\\NC_3H_5\end{matrix}\right\rangle C_2O_2$ [157°].

Reference.—OXY-TOLYL-ALLYL-THIO-UREA.

o-**TOLYL-AMIDO-ACETIC ACID** $C_9H_{11}NO_2$ *i.e.* $C_6H_4Me\ NH.CH_2.CO_2H$. *Tolyl-glycocoll.* [150°]. Prepared by the action of chloro-acetic acid and aqueous NaOAc on o-toluidine (Staats, *B.* 13, 137; Cosack, *B.* 13, 1091; Ehrlich, *B.* 16, 204; Bischoff a. Nastvogel, *B.* 22, 1787).—CuA'_2 2aq. Small needles.—CaA'_2 3aq: needles, m. sol. water (Mauthner, *M.* 11, 377).

Ethyl ether EtA'. (281°). S.G. $\frac{20}{20}$ 1·058. Oil (Bischoff, *B.* 25, 2270).

Acetyl derivative $C_7N_7NAc.CH_2.CO_2H$. [212°]. Tables (from dilute alcohol).

Chloro-acetyl derivative $C_7H_7N(CO.CH_2Cl).CH_2.CO_2H$. [117°]. Formed from the acid and chloro-acetyl chloride in ether (Widman, *J. pr.* [2] 38, 304). Rectangular plates, v. sol. hot alcohol, sl. sol. water.

Bromo-acetyl derivative $C_7H_7N(CO.CH_2Br).CH_2.CO_2H$. [124°]. Rectangular plates.

Glycolyl derivative $C_7H_7N(CO.CH_2.OH).CH_2.CO_2H$. [144°]. Formed by boiling the chloro-acetyl derivative with conc. Na_2CO_3Aq (Abenius, *J. pr.* [2] 40, 503). V. e. sol. water. Yields $KA'aq$, $BaA'_2 7aq$, and AgA', and is converted by heating at 160° into $C_7H_7N{<}\begin{matrix}CO.CH_2\\CH_2.CO\end{matrix}{>}O$ [109°], whence alcoholic NH_3 produces $C_7H_7N(CO.CH_2.OH).CH_2.CO.NH_2$ [152°], crystallising in plates (from alcohol).

o-Toluide $C_7H_7.NH.CH_2.CO.NHC_7H_7$. [92°]. Formed by boiling chloro-acetic ether with *o*-toluidine (Ehrlich, *B.* 16, 205). Needles, insol. water and HClAq.

***m*-Tolyl-amido-acetic acid** [1:3]$C_6H_4Me.NH.CH_2.CO_2H$. Formed from chloro-acetic acid and *m*-toluidine in ether (Ehrlich, *B.* 15, 2011). Solid mass.—$CuA'_2 2aq$.

Ethyl ether EtA′. [68°]. Formed from chloro-acetic ether and *m*-toluidine. Six-sided plates, v. sol. alcohol and ether, sl. sol. Aq.

***p*-Tolyl-amido-acetic acid** [1:4]$C_6H_4Me.NH.CH_2.CO_2H$. [119°]. Formed, together with a compound [168°], from *p*-toluidine chloro-acetic acid and NaOAc (dissolved in a little water) at 100° (P. J. Meyer, *B.* 8, 1158; 14, 1323; Staats, *B.* 13, 137; Schwebel, *B.* 10, 2047; Bischoff, *B.* 23, 1997; 25, 2281). Got also by saponifying its ether. Needles (from water). When fused with potash it yields a product which, when dissolved in water, is oxidised by air to an indigo- derivative (Heumann, *B.* 24, 1346). When fused with *p*-chloro-acet-toluide it yields methyl-indigo (Eckenroth, *B.* 24, 693). The compound [168°], formerly supposed to be *p*-tolyl-amido-acetic acid, ought, according to Bischoff a. Hausdörfer (*B.* 25, 2281) to be represented as $CO_2H.CH_2.N(C_7H_7).CH_2.CO.ONH_3C_7H_7$.

Ethyl ether EtA′. [49°]. Formed from chloro-acetic ether and *p*-toluidine. Monoclinic plates, v. sl. sol. hot water.

Amide $C_9H_{12}N_2O$. [163°]. Formed by heating *p*-toluidine with chloro-acetamide. Plates, v. sl. sol. cold water.

Anilide $C_7H_7NH.CH_2.CO.NHPh$. [83°]. Formed by heating chloro-acetic acid with aniline. Needles (from hot water).

p-Toluide $C_7H_7.NH.CH_2.CO.NC_7H_7$. [136°]. Formed in like manner, and also by heating toluidine with the compound of glyoxal with $NaHSO_3$ (Hinsberg, *B.* 21, 112). Plates, v. sl. sol. hot water. Yields a chloro-acetyl derivative [158°].

Nitrile $C_7H_7NH.CH_2.CN$. [126°]. A product of the action of heat on the amide.

Acetyl derivative $C_7H_7.NAc.CH_2.CO_2H$. [175°]. Formed from chloro-acetic ether and $C_7H_7.NAcNa$, the product being saponified with potash (Paal a. Otten, *B.* 23, 2596). Plates (from water).—$NaA'3aq$: plates, v. sol. water.

Imide $(C_7H_7.NH.CH_2.CO)_2NH$. [210°]. Got by heating the acid at 200° and adding NH_3Aq to the product. Needles, sl. sol. water and NH_3Aq (Bischoff).

Di-*o*-tolyl-di-amido-acetic acid $(C_7H_7NH)_2CH.CO_2H$. [240°]. Formed by heating di-chloro-acetic acid with *o*-toluidine (P. Meyer, *B.* 16, 925). Needles, insol. water, sl. sol. alcohol, v. sol. aqueous acids and alkalis.

Reference.—NITRO-TOLYL-AMIDO-ACETIC ACID.

***p*-TOLYL-AMIDO-ACETOPHENONE** [1:4]$C_6H_4Me.NH.CH_2.CO.C_6H_5$. *Phenacyl-p-toluidine.* [134°]. Formed from *p*-toluidine and bromo-acetophenone in alcohol (Lellmann a. Donner, *B.* 23, 167). Tables, v. sol. benzene, m. sol. alcohol. Yields, on nitration, [1:3:4]$C_6H_3Me(NO_2).NH.CH_2Bz$ [165°] and a di-nitro- derivative [156°]. Forms $B'HNO_3$ and $B'HCl$.

***p*-TOLYL-AMIDO-ACRYLIC ETHER** [1:4]$C_6H_4Me.NH.CH:CH.CO_2Et$. [116°]. Formed from *p*-toluidine and formyl-acetic ether (Von Pechmann, *B.* 25, 1053). Yellow plates, insol. water and ligroïn. Alcoholic potash yields plates [144°]. Ac_2O forms acetyl-toluidine.

TRI-*p*-TOLYL-TRI-AMIDO-BENZENE $C_{27}H_{27}N_3$ *i.e.* $C_6H_3(NHC_7H_7)_3$. [187°]. Formed by heating phloroglucin with *p*-toluidine at 210° (Minunni, *B.* 21, 1984). Needles, v. sl. sol. cold alcohol. Conc. H_2SO_4 forms a bluish-green solution, turning black on heating.—$B'''HCl$: amorphous; decomposed by water.—$B'''2HCl$: small needles.—$B'''_2H_2PtCl_6$.

Tri-acetyl derivative [193°]. Plates.

Tri-benzoyl derivative [282°]. Minute prisms.

***p*-TOLYL-AMIDO-BENZOYL-(α)-NAPHTHOQUINONE** $C_6H_5.CO.C_6H_3{<}\begin{matrix}CO.C.NHC_6H_4Me.\\CO.CH\end{matrix}$ [197°]. Formed by boiling *p*-toluidine with benzoyl-(α)-naphthoquinone in alcoholic solution for 15 minutes (Kegel, *A.* 247, 185). Red needles (from HOAc), v. sl. sol. alcohol.

***p*-TOLYL-*o*-AMIDO-BENZYL-AMINE** [4:1] $C_6H_4Me.NH.CH_2.C_6H_4.NH_2$ [1:2]. [80·5°]. Got by reducing *p*-tolyl-*o*-nitro-benzyl-amine (Söderbaum a. Widman, *B.* 23, 2187). Thin leaflets (from alcohol). Ac_2O yields a di-acetyl derivative [186°]. The mono-acetyl derivative $C_7H_7NAc.CH_2.C_6H_4NH_2$ [99°] may be got by reducing $C_7H_7NAc.CH_2.C_6H_4NO_2$.

***o*-TOLYL-α-AMIDO-*n*-BUTYRIC ACID** $C_7H_7.NH.CHEt.CO_2H$. [84°]. Long prisms. Forms an acetyl derivative [116°] and yields propyl-*o*-toluidine on distillation.

Ethyl ether EtA′. (278°). S.G. $\frac{20}{20}$ 1·019. Got by heating *o*-toluidine with α-bromo-butyric ether at 100° (Bischoff a. Mintz, *B.* 25, 2314).

***o*-Tolyl-α-amido-isobutyric acid** $C_7H_7NH.CMe_2.CO_2H$. [62°]. Formed together with the β- isomeride [110°] by the action of KOH and a current of steam on the ether [57°], which is got by heating *o*-toluidine with α-bromo-isobutyric ether (Bischoff a. Mintz, *B.* 25, 2334). The acid [110°] yields an acetyl derivative [219°], sl. sol. ether. On distillation it forms a lactone [95°].

***p*-Tolyl-α-amido-*n*-butyric acid** $C_7H_7NH.CHEt.CO_2H$. [153°–156°]. Got from the ether EtA′ (279°) S.G. $\frac{20}{20}$ 1·011, which is produced when *p*-toluidine is heated with α-bromo-*n*-butyric acid at 105°. Leaflets. Yields propyl-*p*-toluidine on distillation.

Acetyl derivative $C_7H_7NAc.CHEt.CO_2H$. [149°].

***p*-Tolyl-α-amido-isobutyric acid** [1:4] $C_6H_4Me.NH.CMe_2.CO_2H$. [150°]. Formed, together with the β- isomeride, by the action of hot potash in a current of steam on the ether EtA′ [36°], which is got by heating *p*-toluidine with α-bromo-isobutyric acid. Yields an acetyl derivative [146°]. Forms isopropyl-*p*-toluidine on distillation.

_p_-Tolyl-β-amido-isobutyric acid $C_7H_7NH.CH_2.CHMe.CO_2H$. [196°]. Formed as above. Gives an acetyl derivative [206°] and decomposes on distillation into *p*-toluidine and a lactone $C_7H_7N\left<\begin{matrix}CH_2.CHMe\\CO.CMe_2.O\end{matrix}\right>CO$ (?) [170°].

***o*-TOLYL-AMIDO-CROTONIC ACID** [1:2] $C_6H_4Me.NH.CMe{:}CH.CO_2H$.

Methyl ether MeA'. [31°]. Formed by the action of *o*-toluidine on methyl aceto-acetate (Conrad a. Limpach, *B.* 21, 523). Prisms (from alcohol).

Ethyl ether EtA'. Yellowish oil.

_p_-Tolyl-amido-crotonic acid.

Methyl ether MeA'. [60°]. Prisms.

Ethyl ether EtA'. [29°]. Formed from acetoacetic ether and *p*-toluidine.

TOLYL-AMIDO-CYANURIC ACID *v.* *Cyanuric acid*, described under Cyanic acids.

***p*-TOLYL-AMIDO-METHENYL-BENZAMIDOXIM** $CPh\left<\begin{matrix}N.O\\N\end{matrix}\right>C.NH.C_6H_4Me$ [1:4.]. [135°]. Formed by heating *p*-tolyl-thiocarbimide with benzamidoxim (Koch, *B.* 24, 398). Plates (from alcohol), v. sol. ether.

DI-*p*-TOLYL-AMIDO-METHYLENE-*o*-PHENYLENE DIAMINE $C_{21}H_{22}N_4$ *i.e.* $C_6H_4\left<\begin{matrix}NH\\NH\end{matrix}\right>C\left<\begin{matrix}NH.C_7H_7\\NH.C_7H_7\end{matrix}\right.$. [186°]. (above 400°). Formed by heating $C(NC_7H_7)_2$ with *o*-phenylene-diamine at 135° (Moore, *B.* 22, 1639; 3188). Tables (from alcohol), v. sl. sol. boiling water. —Salts: $B'_2 3HCl$. Needles.—$B'_4 3H_2PtCl_6$ 8aq. —$B'H_2SO_4$. Needles, insol. ether, v. sol. hot Aq.

Nitrosamine $C_6H_4\left<\begin{matrix}N(NO)\\N(NO)\end{matrix}\right>C(NC_7H_7.NO)_2$. [130°]. Yellow needles, v. sol. alcohol.

Di-acetyl derivative [143°]. Needles.

Di-benzoyl derivative [185°]. Prisms.

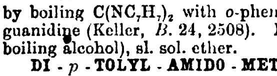
Tetra-benzoyl derivative [274°].

Tetra-*p*-tolyl-tetra-amido-di-methylene-*o*-phenylene-diamine $C_6H_4{:}N_2(C(NHC_7H_7)_2)_2$. [116°]. Formed by heating $C(NC_7H_7)_2$ with *o*-phenylene-diamine at 200° (Moore, *B.* 22, 3195). Needles, v. sol. alcohol. Decomposed by dilute HClAq at 150° into di-*p*-tolyl-urea and *o*-phenylene-diamine. $B'2H_2SO_4$. Needles, sl. sol. cold water.—$B'_2 3HCl$.—$B'_4 3H_2PtCl_6$ 15aq.

Tetra-acetyl derivative [115°].

Tetra-benzoyl derivative [146°].

DI-*p*-TOLYL-AMIDO-METHYLENE-*o*-PHENYLENE-PHENYL-GUANIDINE



$C_6H_4\left<\begin{matrix}N\\N\end{matrix}\right>C{:}NPh\Big>C(NHC_7H_7)_2$. [187°]. Formed by boiling $C(NC_7H_7)_2$ with *o*-phenylene-phenyl-guanidine (Keller, *B.* 24, 2508). Needles (from boiling alcohol), sl. sol. ether.

DI-*p*-TOLYL-AMIDO-METHYLENE-*o*-PHENYLENE-*p*-TOLYL-GUANIDINE $C_6H_4{:}N_2(CNC_7H_7){:}C(NHC_7H_7)_2$. [188°]. Formed by heating *o*-phenylene-*p*-tolyl-guanidine with $C(NC_7H_7)_2$ at 220° (Keller, *B.* 24, 2513). Prisms (from benzene).

DI-*p*-TOLYL-AMIDO-METHYLENE-*o*-TOLYLENE-*p*-TOLYL-GUANIDINE $C_7H_6{:}N_2(C{:}NC_7H_7){:}C(NHC_7H_7)_2$. [210°]. Formed by heating tolylene-tolyl-guanidine together with $C(NC_7H_7)_2$ at 220° (Keller, *B.* 24, 2521). Needles, sl. sol. alcohol.

***o*-TOLYL-AMIDO-METHYL-MALONAMIC ETHER** $CO_2Et.CMe(NHC_7H_7).CO.NH_2$. Formed by dissolving α-cyano-tolyl-α-amido-propionic ether in conc. H_2SO_4 (Gerson, *B.* 19, 2966). Long needles, sol. hot water. Converted by boiling NaOHAq into tolyl-amido-propionic acid.

***p*-TOLYL-AMIDO-*p*-METHYL-OXINDOLE** $C_{16}H_{16}N_2O$ *i.e.* $C_6H_3Me\left<\begin{matrix}NH\\CH(NHC_7H_7)\end{matrix}\right>CO$. [167°]. Formed by heating di-chloro- (or di-bromo-) acetic acid with *p*-toluidine (Duisberg, *B.* 18, 190). Needles, v. sol. hot alcohol. Reduces ammoniacal $AgNO_3$, forming a mirror. Readily absorbs oxygen from the air, forming $C_6H_3Me\left<\begin{matrix}NH\\C(NC_7H_7)\end{matrix}\right>CO$. Alcoholic KOH forms a blood-red solution. B'HCl: crystalline powder.

Di-acetyl derivative $C_{16}H_{14}Ac_2N_2O$. [117°].

Nitrosamine $C_{16}H_{15}N_3O_2$. [c. 220°].

***p*-TOLYL-AMIDO-METHYL-THIAZOLE** $S\left<\begin{matrix}CH - CMe\\C(NHC_7H_7){:}N\end{matrix}\right.$. [125°]. Formed from oxy-methyl-thiazole and *p*-toluidine (Hantzsch a. Weber, *B.* 20, 3130).

TRI-*p*-TOLYL-TRI-AMIDO-NAPHTHALENE $C_6H_4\left<\begin{matrix}C(NHC_7H_7){:}C(NHC_7H_7)\\C(NHC_7H_7){:}CH\end{matrix}\right.$. [160°]. Formed by heating nitroso-ethyl-(α)-naphthylamine with *p*-toluidine at 150° (Fischer a. Hepp, *A.* 256, 244). Needles (from alcohol). Readily oxidised to di-methyl-phenyl-rosinduline.

***o*-TOLYL-AMIDO-(α)-NAPHTHOQUINONE** $C_{17}H_{13}NO_2$ *i.e.* $C_{10}H_5O_2(NHC_7H_7)$. [142°]. Formed from *o*-toluidine and (α)-naphthoquinone (Elsbach, *B.* 15, 689). Red needles, sol. NaOHAq.

_p_-Tolyl-amido-(α)-naphthoquinone $C_{10}H_5O_2(NHC_7H_7)$. [202°]. Formed from (α)-naphthoquinone and *p*-toluidine in hot alcoholic solution (Plimpton, *C. J.* 37, 638). Formed also by the action of *p*-toluidine on (β)-oxy-(α)-naphthoquinone, and by heating *p*-tolyl-amido-(β)-naphthoquinone with HOAc at 150° (Elsbach, *B.* 15, 687). Red needles. Forms a crimson solution in conc. H_2SO_4. Insol. NaOHAq.

Ditoluide $C_6H_4\left<\begin{matrix}C(NC_7H_7){:}C.NHC_7H_7\\C(NC_7H_7){:}CH\end{matrix}\right.$. [147°]. Formed by oxidation of tri-*p*-tolyl-amido-naphthalene (Fischer a. Hepp, *A.* 256, 246). Orange plates.

_o_-Tolyl-amido-(β)-naphthoquinone $C_{10}H_5O_2(NHC_7H_7)$ or $C_{10}H_5(OH)O(NC_7H_7)$. [240°]. Formed from (β)-naphthoquinone and *o*-toluidine (Elsbach, *B.* 15, 689). Red needles, sol. dilute NaOHAq. Not affected by heating with HOAc at 150°. On heating with dilute HClAq it yields (β)-oxy-(α)-naphthoquinone and *o*-toluidine.

_p_-Tolyl-amido-(β)-naphthoquinone [246°]. Formed from (β)-naphthoquinone and *p*-toluidine (Elsbach, *B.* 15, 686). Red needles, sol. hot alcohol and NaOHAq. On heating with HClAq at 130° it is split up into *p*-toluidine and (β)-naphthoquinone.

Methyl ether MeA'. [150°]. Red crystals (Zincke a. Brauns, *B.* 15, 1969).

Ethyl ether EtA'. [137°].

Isopropyl ether PrA'. [139°].

p-Toluide $C_{10}H_5(NHC_7H_7)O(NC_7H_7)$. [183° cor.]. Formed by heating di-bromo-(α)-naphthol with *p*-toluidine (Meldola, *C. J.* 45, 159). Formed also from (β)-naphthoquinone oxim, *p*-toluidine, and HOAc (Bromme, *B.* 21, 391). Orange crystals with green lustre.

DI-*o*-TOLYL-DI-AMIDO-OIAZTHIOLE $C_{16}H_{16}N_4S$ *i.e.* $S<\begin{matrix}C(NHC_7H_7):N\\ C(NHC_7H_7):N\end{matrix}$. [135°]. Formed by boiling an alcoholic solution of *o*-tolyl-thio-urea with dilute HClAq and H_2O_2 (Hector, *B.* 23, 368). V. sol. alcohol. Cyanogen passed into its alcoholic solution forms $C_{16}H_{16}N_4SCy_2$ [89°].—$B'HCl$aq. [219°].—$B'_2H_2PtCl_6$. [192°].—$B'AgNO_3$. White pp.—$B'_2H_2HgCl_4$. [232°]. Needles.—Picrate: $B'C_6H_3N_3O_7$. [201°].

Acetyl derivative $C_{16}H_{15}AcN_4S$. [221°].

Benzoyl derivative $C_{16}H_{15}BzN_4S$. [214°].

Nitrosamine $C_{16}H_{15}(NO)N_4S$. [135°].

Di-*p*-tolyl-di-amido-oiazthiole $C_{16}H_{16}N_4S$. [127°]. Formed in like manner from *p*-tolyl-thio-urea (Hector, *B.* 23, 364). Thick yellowish prisms, v. sol. alcohol. Cyanogen forms $B'Cy_2$ [190°].—$B'HCl$. [233°]. White needles, becoming reddish in air.—$B'_2H_2PtCl_6$ 1½aq. [109°].—$B'AgNO_3$ 1½aq. [177°].—$B'_2H_2HgCl_4$. [114°–119°].—Picrate [238°]. Yellow prisms, sl. sol. alcohol.

Acetyl derivative $C_{16}H_{15}AcN_4S$. [166°].

Benzoyl derivative $C_{16}H_{15}BzN_4S$. [186°].

Nitrosamine $C_{16}H_{15}(NO)N_4S$. [247°].

***o*-TOLYL-*m*-AMIDO-PHENOL** $C_{13}H_{13}NO$ *i.e.* $C_7H_7NH.C_6H_4OH$. (c. 373° cor.). Formed from resorcin, *o*-toluidine, and $CaCl_2$ at 270° (Philip, *J. pr.* [2] 34, 70). Oil. Reduced by hot zinc-dust to hydro-acridine and acridine.

Formyl derivative. [169°]. Tables.

***o*-Tolyl-*p*-amido-phenol** $C_7H_7NH.C_6H_4OH$. [90°]. (367° cor.). Formed from hydroquinone, *o*-toluidine and $CaCl_2$ at 240° (Philip, *J. pr.* [2] 34, 57). White laminæ (from light petroleum). Reduced by distilling with zinc to hydro-acridine and acridine. Converted by heating with conc. HCl into hydroquinone and *o*-toluidine.

Salt.—$B'HCl$: crystalline powder.

Mono-formyl derivative [136·5°].

Di-acetyl derivative [106°]: needles.

Di-benzoyl derivative. [171°].

***p*-tolyl-*m*-amido-phenol** $C_{13}H_{13}NO$ *i.e.* $C_7H_7.NH.C_6H_4.OH$. [92°]. (350° cor.). From resorcin, *p*-toluidine and $CaCl_2$ at 260° for 8 hours (Hatschek a. Zega, *J. pr.* [2] 33, 209). Prisms or needles (from benzene mixed with petroleum ether). Distilled over zinc-dust, it gives C_7H_7NHPh.

Salts.—$B'HCl$; decomposed by water.

Formyl derivative.—$C_7H_7.N(CHO).C_6H_4.OH$. [146°]. V. sol. ether.

Di-benzoyl derivative.—$C_7H_7.NBzC_6H_4.OBz$. [c. 105°]. Gives with fuming HNO_3 a di-nitro-derivative, [110°].

Nitrosamine.—$C_7H_7.N(NO).C_6H_4.OH$. *Oxy-phenyl-tolyl-nitrosamine.* [105°]. Yellow needles (from dil. alcohol).

***p*-Tolyl-*p*-amido-phenol** $C_7H_7.NH.C_6H_4.OH$. [122°]. (350°–360°). From hydroquinone, *p*-toluidine, and $CaCl_2$ 8 hours at 260° (Hatschek a. Zega, *J. pr.* [2] 33, 224). Plates. Heated with zinc-dust it gives phenyl-*p*-tolyl-amine.

Salt.—$B'HCl$. Powder, decomposed by Aq.

Di-acetyl derivative. [101°]. Tables.

Di-benzoyl derivative. [169°].

Nitroso- derivative $C_7H_7.N(NO).C_6H_4.OH$ [130°]; needles. Very unstable.

***o*-TOLYL-α-AMIDO-PHENYL-ACETIC ACID** $NHC_7H_7.CHPh.CO_2H$. [143°]. Formed from α-bromo-phenyl-acetic acid and *o*-toluidine (Stöckenius, *J.* 1878, 781). Plates, almost insol. water.

***p*-Tolyl-α-amido-phenyl-acetic acid.** Formed in like manner, using *p*-toluidine. Insol. water.

Ethyl ether EtA'. [90°]. Yellowish prisms.

***o*-TOLYL-AMIDO-TRI-PHENYL-METHANE** $CPh_3.NHC_7H_7$. [142°]. Formed from CPh_3Br and *o*-toluidine (Wittich, *B.* 17, 705). Prisms (from ether).

***p*-Tolyl-amido-tri-phenyl-methane** [177°]. Crystals (from ether).

Nitrosamine $CPh_3.NC_7H_7.NO$. [145°–148°].

***p*-TOLYL-AMIDO-DI-PHENYL-NAPHTHO-QUINOXALINE.** *Phenylo-chloride*

$$C_6H_4<\begin{matrix}\overline{\qquad\qquad\qquad\qquad}C.N\!=\!\!=\!CPh\\ C(NH.C_6H_4Me):CH.\,C.NPhCl:CPh.\end{matrix}$$

Got by heating $C_{10}H_5(OEt)<\begin{matrix}N\!=\!\!=\!CPh\\ NPhCl:CPh\end{matrix}$ with *p*-toluidine at 120° (Witt a. Schmidt, *B.* 25, 2005). Bronzed plates, v. sol. alcohol, forming a crimson solution. Conc. H_2SO_4 forms a slate-blue solution, becoming first blue and then violet on dilution.

TRI-*p*-TOLYL-TRI-AMIDO-DI-PHENYL-TOLYL-CARBINOL $C_{41}H_{39}N_3O$. *Tri-tolyl-rosaniline.* The salts are formed by heating rosaniline salts with *p*-toluidine (Hofmann, *A.* 132, 290).—$C_{41}H_{38}N_3Cl$. Small blue crystals (from alcohol), insol. water.

TOLYL-AMIDO-PIPITZAHOIC ACID *v.* *Toluido*-PIPITZAHOIC ACID.

***o*-TOLYL-α-AMIDO-PROPIONIC ACID** $CH_3.CH(NHC_7H_7).CO_2H$. [116°]. Formed by saponification of the nitrile (Tiemann a. Stephan, *B.* 15, 2038; *C. C.* 1886, 470). Got also by boiling *o*-tolyl-amido-methyl-malonic acid with NaOHAq (Gerson, *B.* 19, 2963). White crystals.

Ethyl ether EtA' (278°). S.G. $\frac{20}{20}$ 1·047. Formed from α-bromo-propionic ether and *o*-toluidine (Bischoff a. Hausdörfer, *B.* 25, 2298).

Acetyl derivative $C_7H_7NAc.CHMeCO_2H$. [177°]. Leaflets.

Amide. [125°]. Minute needles.

Nitrile $CH_3.CH(NHC_7H_7).CN$. [73°]. Formed by digesting the cyanhydrin of acetic aldehyde (lactonitrile) with *o*-toluidine.

***p*-Tolyl-α-amido-propionic acid.** [153°]. Formed in like manner. Plates, sl. sol. water and ether. May be sublimed.

Ethyl ether EtA'. [35°]. Tables.

Acetyl derivative [166°].

Amide. [145°]. Needles, sol. hot Aq.

Nitrile. [82°]. Plates, sl. sol. hot Aq.

***p*-Tolyl-β-amido-propionic acid** $C_6H_4Me.NH.CH_2.CH_2.CO_2H$. [86°]. Formed from β-iodo propionic acid and *p*-toluidine (Bischoff a. Mintz, *B.* 25, 2352). Pearly scales, v. e. sol. ether.

Reference. — DI-BROMO-TOLYL-AMIDO-PROPIONITRILE.

***o*-TOLYL-AMIDO-PYROTARTRIMIDE** $\begin{matrix}CH_2.CO\text{—}NH\\ CH_2.C(NHC_7H_7).CO\end{matrix}$. [181°]. Obtained by saponification of *o*-tolyl-amido-pyrotartramic ether, which is formed by the action of H_2SO_4 upon the *a*-cyano-*a*-*o*-toluido-butyric ether (Schiller-Wechler, *B.* 18, 1050). White needles. V. sol. alcohol and benzene, sl. sol. ether and hot water, insol. cold water and ligroïn. Has both acid and basic properties.

DI-*p*-TOLYL-DI-AMIDO-SUCCINIC ACID $CO_2H.CH(NHC_7H_7).CH(NHC_7H_7).CO_2H$. [c. 200°]. Formed, together with 'di-tolil succin' $C_{18}H_{16}N_2O_2$ [228°], by boiling di-bromo-succinic acid with *p*-toluidine (Jungliahn a. Roissert, *B.* 26, 1766). V. sol. alcohol, insol. water. Yields a di-nitroso- derivative [125°], and a di-acetyl derivative $C_{22}H_{24}N_2O_6$ aq, which yields CaA″ aq, BaA″ aq, and anhydrides $C_{22}H_{22}N_2O_5$ [232°], and $C_{22}H_{20}N_2O_4$ [222°]. Na_2A''.—CaA″.—CuA″.

Ethyl ether Et_2A''. [169°]. Needles.

DI-*p*-TOLYL-TRI-AMIDO-TOLUENE $C_6H_2Me(NHC_7H_7)_2(NH_2)$ [1:2:5:4]. [166°]. Formed by reducing amido-toluquinone ditoluide with zinc-dust and HOAc (Green, *C. J.* 63, 1403; *cf.* Barsilowsky, *B.* 6, 1209). Plates (from dilute HOAc). A very feeble base.

DI-*p*-TOLYL-DI-AMIDO-TOLUQUINONE $C_6HMeO_2(NHC_7H_7)_2$ [1:2:5:4:6]. [178°]. Formed from azotoline, MeOH, and conc. H_2SO_4 (Fischer a. Hepp, *A.* 262, 251). Brownish-red needles.

Di-*p*-tolyl-di-amido-toluquinone $C_6HMeO_2(NHC_7H_7)_2$ [1:2:5:3:6]. [241°]. Formed by boiling toluquinone with *p*-toluidine and alcohol (Fischer a. Hepp, *A.* 256, 259). Yellow needles.

Di-*p*-tolyl-di-amido-toluquinone *p*-toluide $C_{28}H_{27}N_3O$. [191°]. Claret-red plates (Fischer a. Hepp, *B.* 21, 676).

TOLYLAMINE is Toluidine (*q.v.*).

Di-*o*-tolyl-amine $NH(C_6H_4Me[1:2])_2$. (312° i.V.) at 728 mm. (Graebe, *A.* 238, 363). Obtained, together with diphenylamine by heating *o*-toluidine with aniline hydrochloride at 280° (Girard a. Willm, *Bl.* [2] 25, 248). Formed also by heating *o*-cresol with $ZnBr_2$, ammonia, and NH_4Cl at 335° (Merz a. Müller, *B.* 20, 547). Oil.

Di-*m*-tolyl-amine $NH(C_7H_7)_2$. (322°). Formed in like manner (Cosack, *B.* 13, 1091; Merz a. Müller, *B.* 20, 549). Oil, volatile with steam. Sl. sol. acids, v. sol. alcohol.

Acetyl derivative $NAc(C_7H_7)_2$. [43°].

Nitrosamine $(C_7H_7)_2N.NO$. [103°].

Di-*p*-tolyl-amine $NH(C_7H_7)_2$. [79°]. (331° i.V.) (Graebe, *A.* 238, 363). Formed by heating *p*-toluidine with its hydrochloride (Girard, *A.* 140, 346; Gerber, *B.* 6, 446). Formed also by heating *p*-cresol with $ZnCl_2$, ammonia, and NH_4Cl at 335° (Merz a. Müller, *B.* 20, 546). White needles. Its salts are decomposed by water.

Nitrosamine $(C_7H_7)_2N.NO$. [103°]. Yellow trimetric crystals (Lehne, *B.* 13, 1514; Cosack).

Acetyl derivative $(C_7H_7)_2NAc$. [85°].

Benzoyl derivative $(C_7H_7)_2NBz$. [125°].

References.—Tetra-bromo- and Nitro- Di-tolyl-amine.

DI-*p*-TOLYL-ISOAMYL-AMINE $C_{19}H_{25}N$ *i.e.* $(C_7H_7)_2NC_5H_{11}$. (290°–300° at 15 mm.). Formed by heating di-*p*-tolyl-amine with isoamyl alcohol and HCl in sealed tubes (Girard, *Bl.* [2] 24, 120).

TOLYL-ANILINE *v.* Phenyl-toluidine.

TOLYL-ARSINE *v.* Arsenic.

TOLYL-AURAMINE $C_{24}H_{27}N_3$ *i.e.* $C_6H_4Me.N:C(C_6H_4NMe_2)_2$. Formed from auramine hydrochloride and *p*-toluidine (Fehrmann, *B.* 20, 2853). Decomposed by H_2S in alcoholic solution at 50° into $CS(C_6H_4NMe_2)_2$ and *p*-toluidine.—$B'_2H_2PtCl_6$. Red flakes, v. sl. sol. water.

TOLYL-AZIMIDO-TOLUENE *v.* Azimido-compounds.

DI-*p*-TOLYL-TETRAZINE $C_{16}H_{16}N_4$ *i.e.* $C_6H_4Me.N{<}\genfrac{}{}{0pt}{}{N{=}CH}{CH{:}N}{>}N.C_6H_4Me$. [185°]. Mol. w. 269 (obs.). Formed by the action of chloroform and alcoholic potash on *p*-tolyl hydrazine (Ruhemann, *C. J.* 55, 218; 57, 51). Yellow plates (from hot alcohol). Yields a nitro-derivative $C_{16}H_{15}(NO_2)N_4$ [144°].

TOLYL-DISAZO-compounds *v.* Disazo-compounds.

TOLYL BENZAMIDE *v.* *Benzoyl derivative* of Toluidine.

***p*-TOLYL-BENZAMIDINE** $C_{14}H_{14}N_2$ *i.e.* $C_6H_5.C(NC_7H_7).NH_2$. [99°]. Formed from benzonitrile and toluidine hydrochloride (Bernthsen, *B.* 8, 1319; 9, 429). Forms a crystalline nitrate and oxalate.

Di-*p*-tolyl-benzamidine $C_6H_5.C(NC_7H_7).NHC_7H_7$. [131°]. Formed by the action of *p*-toluidine on benzonitrile, and on ω-chloro-benzylidene-*p*-toluidine $C_7H_7N:CCl.C_6H_5$ (Bernthsen; Just, *B.* 19, 981). May be sublimed.

Reference.—Amido-tolyl-benzamidine.

***p*-TOLYL-BENZAMIDOXIM** $C_{14}H_{14}N_2O$ *i.e.* $C_6H_5.C(NOH).NHC_7H_7$. [176°]. Formed by heating hydroxylamine hydrochloride with $C_6H_5.CS.NHC_7H_7$ and Na_2CO_3 at 100° (H. Müller, *B.* 22, 2406). White needles, sl. sol. hot water.—B′HCl: white needles, sl. sol. water. $ClCO_2Et$ converts it into $C_6H_5.C{<}\genfrac{}{}{0pt}{}{N.O}{NC_7H_7}{>}CO$. [163°].

TOLYL-BENZENE *v.* Methyl-diphenyl.

Tri-*p*-tolyl-benzene $C_{27}H_{24}$ *i.e.* $C_6H_3(C_7H_7)_3$. [171°]. Formed by passing dry HCl into *p*-tolyl methyl ketone for some days (Claus, *J. pr.* [2] 41, 402). Needles. Oxidised by CrO_3 to $C_6H_3(CO_2H)_3$. Yields $C_{27}H_{21}Br_3$ [212°].

***p*-TOLYL-BENZIMIDO PHENYL ETHER** $C_6H_5.C(NC_7H_7).OPh$. [120°]. Formed from $C_6H_5.CCl:NC_7H_7$ and NaOPh (Hantzsch, *B.* 26, 927).

***om*-TOLYL-BENZOIC ACID** [1:3] $C_6H_4Me.C_6H_4.CO_2H$ [1′:3′]. [204°]. Formed by oxidation of [1:3] $C_6H_4Me.C_6H_4Me$ [1′:3′] with dilute HNO_3 (Perrier, *C. R.* 114, 484). Silky needles, sol. alcohol, m. sol. Aq.

***pp*-Tolyl-benzoic acid** [1:4] $C_6H_4Me.C_6H_4.CO_2H$ [1′:4′]. [244°]. Formed by oxidation of *pp*-ditolyl by CrO_3 and HOAc (Carnelley, *J.* 1877, 384). Sl. sol. hot water.—AgA′.

***op*-Tolyl-benzoic acid.** [180°]. Formed by oxidation of [1:2] $C_6H_4Me.C_6H_4.Me$ [1′:4′] (Carnelley, *C. J.* 37, 707). Insol. water, sol. hot alcohol.

TOLYL-BENZYL-AMINE *v.* Benzyl-toluidine.

***p*-TOLYL-BENZYL-ISOBUTYL-UREA** $C_{19}H_{24}N_2O$. [41°]. Got from *p*-tolyl-benzyl-carbamic chloride and isobutylamine (Hammerich, *B.* 25, 1824). Crystals (from ligroïn).

p-**TOLYL-BENZYL-CARBAMIC CHLORIDE** $(C_6H_4Me)N(CH_2Ph).COCl$. Formed from *p*-tolyl-benzyl-amine and $COCl_2$ (Hammerich, *B.* 25, 1822). Oil.

p-**TOLYL-BENZYL-CARBINOL** $C_{15}H_{16}O$ *i.e.* $C_6H_4Me.CH(OH).CH_2Ph$. [66°]. (above 360°). Formed by reducing *p*-tolyl benzyl ketone in alcoholic solution by Na (Mann, *B.* 14, 1646). Small concentric needles, sol. alcohol and ether.

p-**TOLYL-BENZYLENE-ACETAMIDINE** $C_{16}H_{16}N_2$ *i.e.* $C_6H_4{<}\begin{matrix}CH_2.NC_7H_7\\N = CMe\end{matrix}$. [79°]. Formed by reduction of the acetyl derivative of *o*-nitro-benzyl-*p*-toluidine in acetic acid solution with tin and HCl (Lellmann a. Stickel, *B.* 19, 1610). Small glistening plates. V. sol. alcohol, ether, and chloroform.

p-**TOLYL BENZYL KETONE** $C_{15}H_{11}O$ *i.e.* $C_6H_4Me.CO.CH_2Ph$. [109°]. (above 360°). Formed by the action of $AlCl_3$ on a mixture of phenyl-acetyl chloride and toluene (Mann, *B.* 14, 1646; Strassmann, *B.* 22, 1229). Plates, sol. alcohol and ether. Na added to its alcoholic solution forms the carbinol and an acid $C_{19}H_{20}O_2$ [′3°].

Oxim [131°]. Plates, insol. water.

o-**TOLYL BENZYL OXIDE** $C_{14}H_{11}O$ *i.e.* [1:2] $C_6H_4Me.O.CH_2Ph$. (285°–290°). Oil (Staedel, *B.* 14, 899). Converted by HNO_3 (S.G. 1·5) into a tri-nitro- derivative [145°].

m-**Tolyl benzyl oxide.** [43°]. (300°–305°). Tables (from alcohol), v. sol. ether.

p-**Tolyl benzyl oxide** [41°]. Formed from $C_6H_4Me.OK$ and CH_2PhCl (Frische, *A.* 224, 154). Crystals. Converted by HNO_3 (S.G. 1·5) into di-nitro-*p*-cresol [84°].

TOLYL-BENZYL-ISOPHOSPHINE $C_{14}H_{15}P$ or $C_{27}H_{28}P_2$. [187°]. An indifferent body formed by the action of zinc on a mixture of benzyl chloride and $C_6H_4MePCl_2$ (Michaelis a. Gleichmann, *B.* 15, 1963).

p-**TOLYL BENZYL SULPHONE** $C_6H_4Me.SO_2.CH_2Ph$. [145°]. Formed by the action of benzyl chloride on sodium toluene *p*-sulphinate (Otto, *B.* 13, 1278). Needles, sol. hot alcohol.

p-**TOLYL-BENZYL-THIO-SEMICARBAZIDE** $C_{15}H_{17}N_3S$. [121°]. Formed from benzyl thiocarbimide and *p*-tolyl-hydrazine (Dixon, *C. J.* 61, 1022). Prisms, sl. sol. cold alcohol.

o-**TOLYL-BENZYL-THIO-UREA** $C_{15}H_{16}N_2S$ *i.e.* $C_6H_4MeNH.CS.NHCH_2Ph$. [139°]. Formed by boiling *o*-tolyl-thiocarbimide with benzylamine in alcohol (Dixon, *C. J.* 59, 556). Tufts of prisms, m. sol. hot alcohol.

m-**Tolyl-benzyl-thio-urea.** [114°]. Formed from benzyl-thiocarbimide and *m*-toluidine. Vitreous crystals, v. sl. sol. hot Aq.

p-**Tolyl-benzyl-thio-urea** [121°]. Crystals.

p-**TOLYL-BENZYL-UREA** $CH_2Ph.NH.CO.NHC_6H_4Me$. [181°]. Formed from *p*-tolyl cyanate and benzylamine (Kühn a. Henschel, *B.* 21, 505).

p-**Tolyl-di-benzyl-urea** $C_{22}H_{22}N_2O$ *i.e.* $(CH_2Ph)_2N.CO.NHC_6H_4Me$. [169°]. Got from $(C_7H_7)_2N.COCl$ and *p*-toluidine (Hammerich, *B.* 25, 1820). Needles (from alcohol), insol. ether.

p-**Tolyl-di-benzyl-urea** $C_{22}H_{22}N_2O$ *i.e.* $CH_2PhN(C_6H_4Me).CO.NH.CH_2Ph$. [85°]. Formed from tolyl-benzyl-carbamic chloride and benzylamine (H.). Prisms, v. sol. alcohol.

Di-*p*-tolyl-benzyl-urea $C_{22}H_{22}N_2O$. [115°]. Formed from *p*-tolyl-benzyl-carbamic chloride and *p*-toluidine. Needles, v. sol. hot alcohol.

Di-*p*-tolyl-di-benzyl-urea $(CH_2PhN(C_6H_4Me))_2CO$. [93°]. Got from *p*-tolyl-benzyl-carbamic chloride and *p*-tolyl-benzyl-amine. Crystalline, sol. alcohol.

DI-*p*-TOLYL-BIURET $(C_6H_4MeNH.CO)_2NH$. [c. 220°]. Formed from *p*-tolyl-urea and *p*-tolyl cyanate at 160° (Kühn a. Henschel, *B.* 21, 506). White needles (from alcohol).

Tri-*p*-tolyl-biuret $(C_6H_4MeNH.CO)_2NC_6H_4Me$. [156°]. Formed from di-*p*-tolyl-urea and *p*-tolyl cyanate.

p-**TOLYL-BORIC ACID** $C_6H_4Me.B(OH)_2$. [240°]. Formed by the action of water on boron-*p*-tolyl-dichloride (*v.* vol. i. p. 531). Needles, sol. hot water. $HgCl_2$ gives a white pp. of C_7H_7HgCl.

TOLYL-BROMO-ETHYLENE *v.* BROMO-TOLYL-ETHYLENE.

TOLYL BROMO-METHYL KETONE $C_6H_4Me.CO.CH_2Br$. [55°]. Formed by the action of hot water on di-*exo*-bromo-*eso*-methyl-atrolactic acid (Böttinger, *B.* 14, 1598). Crystals, volatile with steam, sol. water and ether.

p-**TOLYL BROMO-METHYL SULPHONE** $C_6H_4Me.SO_2.CH_2Br$. [92°]. Formed by the action of bromine on an aqueous solution of $C_7H_7.SO_2.CH_2.CO_2H$ (Otto, *J. pr.* [2] 40, 544). Formed also from $C_7H_7.SO_2Na$ and CH_2Br_2. Thin monoclinic needles, sol. hot alcohol.

p-**Tolyl di-bromo-methyl sulphone** $C_6H_4Me.SO_2.CHBr_2$. [117°]. Formed from tolyl-sulphono-acetic acid and Br (O.). Monoclinic prisms, v. sol. hot alcohol.

TOLYL-BUTANE *v.* BUTYL-TOLUENE.

m-**TOLYL-BUTYLENE** $C_6H_4Me.CH_2.C_3H_5$. (195°). Formed from $C_6H_4Me.CH_2Cl$, allyl iodide, and Na (Aronheim, *B.* 9, 1790). Oil. Yields a liquid dibromide.

p-**TOLYL-*p*-BUTYL-PHENYL-THIO-UREA** $C_6H_4Me.NH.CS.NH.C_6H_4.C_4H_9$. [137°]. Formed from isobutyl-phenyl-amine and *p*-tolyl-thio-carbimide (Mainzer, *B.* 16, 2024). Plates, sol. alcohol and ether.

DI-*p*-TOLYL-ISOBUTYL-UREA $C_{19}H_{24}N_2O$. [119°]. Formed from $(C_7H_7)_2N.COCl$ and isobutylamine (Hammerich, *B.* 25, 1822). Prisms, v. sol. alcohol and ether.

m-**TOLYL-ISOBUTYRIC ACID** $C_6H_4Me.CH_2.CHMe.CO_2H$. [92°]. Formed by oxidation of *m*-isobutyl-toluene by dilute HNO_3 (Kelbe, *B.* 16, 620). Needles (from ligroïn).—AgA′: pp.

Reference.—NITRO-TOLYL-ISOBUTYRIC ACID.

o-**TOLYL-CARBAMIC ACID** $C_8H_9NO_2$ *i.e.* $C_6H_4Me.NH.CO_2H$.

Ethyl ether EtA′. [42°] (C.); [46°] (L.). Formed from *o*-toluidine and $ClCO_2Et$ (Cosack, *B.* 12, 1450; Nevile a. Winther, *B.* 12, 2324). Formed also from $C_6H_4Me.CCl{:}NCl$ and alcoholic potash (Lachmann, *B.* 12, 1349). Tables, sol. alcohol and benzene. Volatile with steam. Yields *o*-tolyl cyanate on distilling with P_2O_5.

Isobutyl ether C_4H_9A'. (275°–280°). Oil (Mylius, *B.* 5, 974). Partially decomposed on distillation into tolyl cyanate and isobutyl alcohol.

Benzyl ether CH_2PhA'. [84°]. Formed from *o*-tolyl cyanate and benzyl alcohol (Gattermann a. Cantzler, *B.* 25, 1087). Needles

Phenyl ether PhA'. [92°]. Formed by boiling di-*o*-tolyl-urea with di-phenyl carbonate for some hours (Eckenroth a. Rückel, *B.* 23, 699). Crystals (from ligroïn).

m-Phenylene ether $C_6H_4A'_2$. [154°]. Formed by heating *o*-tolyl cyanate with resorcin at 120° (G. a. C.). Colourless plates.

p-Phenylene ether $C_6H_4A'_2$. [206·5°]. Formed by heating *o*-tolyl cyanate with hydroquinone at 150°.

o-Tolyl ether C_7H_7A'. [126°]. Formed from *o*-tolyl cyanate and *o*-cresol (G. a. C.). Needles.

(β)-*Naphthyl ether* $C_{10}H_7A'$. [149°]. Formed by heating *o*-tolyl cyanate with (β)-naphthol at 160° (G. a. C.). Plates.

Di-phenyl-ethylene ether $C_2H_2Ph_2A'_2$. [234°]. Formed by heating *o*-tolyl cyanate with hydrobenzoïn at 100° (Auwers, *B.* 24, 1778). Needles. An isomeride [163°] is obtained from isohydrobenzoïn.

***m*-Tolyl-carbamic acid** $[1:3]C_6H_4Me.NH.CO_2H$.

Ethyl ether $C_{10}H_{13}NO_2$. Prepared from *m*-toluidine and chloro-formic ether (Cosack, *B.* 13, 1090). Oil, v. sol. alcohol and ether.

***p*-Tolyl-carbamic acid** $[1:4]C_6H_4Me.NH.CO_2H$.

Ethyl ether EtA'. [52°]. Formed from *p*-toluidine and $ClCO_2Et$ (Hofmann, *Pr.* 19, 108; *B.* 3, 656). Monoclinic prisms, v. sol. alcohol (Levin, *J.* 1882, 384).

Phenyl ether PhA'. [115°]. Formed by distilling di-*p*-tolyl-urea with di-phenyl carbonate (Eckenroth a. Rückel, *B.* 23, 698). Needles (from hot ligroïn).

Di-*p*-tolyl-carbamic acid $(C_7H_7)_2N.CO_2H$.

Ethyl ether EtA'. [62°]. Formed from $(C_7H_7)_2N.COCl$ and NaOEt (Hammerich, *B.* 25, 1824). Large plates, v. sol. alcohol and ether.

Chloride $(C_6H_4Me)_2N.COCl$. [103°]. Formed from $COCl_2$, a solution of di-*p*-tolylamine in benzene, and conc. NaOHAq (Hammerich, *B.* 25, 1821). Needles (from alcohol), v. e. sol. ether. AgCy forms the compound $(C_7H_7)_2N.CO.CN(AgCy)_2$ crystallising in needles which begin to melt at 103°.

***o*-TOLYL-CARBAMINE** $[1:2]C_6H_4Me.N:C$. (184°). S.G. ^{24} ·968. Formed by the action of alcoholic potash on *o*-toluidine and chloroform (Nef, *A.* 270, 309). Oil, volatile with steam. When heated at 245° for 3 hours it changes to the isomeric *o*-toluic nitrile. Heated with S in CS_2 at 130° it yields *o*-tolyl thiocarbimide. H_2S at 100° forms $C_6H_4Me.NH.CHS$ [101°].

Chloride $C_6H_4Me.N:CCl_2$. (215°). Formed by passing chlorine into a chloroform solution of the carbamine.

***p*-Tolyl-carbamine** $C_6H_4Me.N:C$. (99° at 36 mm.). Formed in like manner from *p*-toluidine (Nef). Oil.

Chloride $C_6H_4Me.N:CCl_2$. (226°). Converted by *p*-toluidine into tri-*p*-tolyl-guanidine.

***o*-TOLYL-SEMI-CARBAZIDE** $C_8H_{11}N_3O$ *i.e.* $NH_2.CO.N_2H_2C_7H_7$. [160°]. Formed by heating *o*-tolyl-hydrazine with urea (Pinner, *B.* 21, 1219). Flat needles, m. sol. water.

***p*-Tolyl-semi-carbazide** $C_8H_{11}N_3O$. [158°]. Sl. sol. cold water. Reduces Fehling's solution.

Di-*p*-tolyl-carbazide $CO(NH.NHC_7H_7)_2$. [201°]. Formed from *p*-tolyl-hydrazine and carbamic ether (Preund, *B.* 24, 4197). Tables, insol. water, v. sol. hot alcohol.

TOLYL-CARBIMIDE v. TOLYL ISOCYANATE, vol. ii. p. 316.

***o*-TOLYL-CARBINOL** $C_8H_{10}O$ *i.e.* $[1:2]C_6H_4Me.CH_2OH$. *ω-Oxy-o-xylene.* Mol. w. 122. [34°]. (223° i.V.). S.G. ^{49} 1·02. S. 1 in the cold; 1·5 at 100°. Formed by boiling *ω*-bromo-*o*-xylene with KOHAq (Colson, *Bl.* [2] 43, 8; *A. Ch.* [6] 6, 116). Formed also by reducing the aldehyde $C_6H_4Me.CHO$ (Raymann, *Bl.* [2] 27, 498), by the action of HNO_2 on the amine $C_6H_4Me.CH_2.NH_2$ (Kröber, *B.* 23, 1028), and by reducing *o*-toluic amide in acid solution by sodium-amalgam (Hutchinson, *B.* 24, 174). Needles, v. sol. alcohol and ether, sol. hot water. Oxidised by alkaline $KMnO_4$ to *o*-toluic acid [103°].

***m*-Tolyl-carbinol** $[1:3]C_6H_4Me.CH_2.OH$. (217°). S.G. ^{0} 1·036 (C.); ^{17} ·916 (R. a. W.). S. 5 in the cold. Formed by boiling the bromide $C_6H_4Me.CH_2Br$ with alkalis (C.). Liquid, v. sol. alcohol and ether, sl. sol. cold water. Yields *m*-toluic acid [108°] on oxidation.

Ethyl ether $C_7H_7.CH_2.OEt$. (202°) at 740 mm. S.G. ^{17} ·93. Oil.

Acetyl derivative $C_7H_7.CH_2.OAc$. (226°). Formed from $C_7H_7.CH_2Br$ and KOAc (Radziszewski a. Wispek, *B.* 15, 1747). Oil.

***p*-Tolyl-carbinol** $[1:4]C_6H_4Me.CH_2OH$. [59°]. (217°). Formed from *p*-toluic aldehyde and alcoholic potash (Cannizzaro, *C. R.* 54, 1225; *A.* 124, 255). Needles, sl. sol. cold water.

Ethyl ether $C_8H_9.OEt$. (203°) at 740 mm. S.G. ^{17} ·93. Formed from *ω*-bromo-*p*-xylene and alcoholic potash (Radziszewski a. Wispek, *B.* 15, 1745). Oil.

Di-tolyl-carbinol $(C_6H_4Me)_2CH.OH$. [69°] (W.); [62°] (Ador a. Crafts, *B.* 10, 2175). Formed by reducing di-tolyl ketone with sodium-amalgam (Weller, *B.* 7, 1184). Needles (from alcohol), insol. water.

Reference.—OXY-TOLYL-CARBINOL.

TOLYL-CARBINYL-AMINE v. METHYL-BENZYL-AMINE.

DI-*p*-TOLYL-CARBINYL AMINE $(C_7H_7)_2CH.NH_2$. [93°]. Formed by reducing the oxim of di-*p*-tolyl ketone in alcoholic solution with sodium-amalgam and HOAc at 60° (Goldschmidt a. Stöcker, *B.* 24, 2798). Tables.—B'HCl. [235°]. White needles.

Acetyl derivative [159°]. Needles.

TOLYL-CARBINYL-UREA v. METHYL-BENZYL-UREA.

Di-*p*-tolyl-carbinyl-urea $NH_2.CO.NH.CH(C_7H_7)_2$. [152°]. Formed from the hydrochloride of the amine and KCyO (Goldschmidt, *B.* 24, 2799). Needles.

DI-*p*-TOLYL-CARBONATE $(C_7H_7O)_2CO$. [115°]. Formed, together with di-ethyl carbonate, by heating *p*-tolyl ethyl carbonate at 300° (Bender, *B.* 19, 2268). V. sl. sol. cold alcohol.

DI-TOLYL DICARBOXYLIC ACID $[3:4:1]C_6H_3Me(CO_2H).C_6H_3Me(CO_2H)[1:3:4]$ [over 300°]. Formed by heating its nitrile with dilute H_2SO_4 (Löwenherz, *B.* 25, 1036). Plates, insol. water, sl. sol. hot alcohol.

Nitrile $C_{14}H_{12}(CN)_2$. [190°]. Formed from di-amido-ditolyl by Sandmeyer's diazo- reaction. Needles, m. sol. cold alcohol.

Reference.—OXY-DITOLYL DICARBOXYLIC ACID.

TOLYL CHLORIDE v. *ω*-CHLORO-XYLENE.

p-**TOLYL CHLORO-BENZYL SULPHONE** $C_6H_4Me.SO_2.CHCl.C_6H_5$. [203°]. Formed by heating sodium toluene *p*-sulphinate with benzylidene chloride (Otto, *J. pr.* [2] 40, 519). Needles (from HOAc).

p-**TOLYL CHLORO-ETHYL SULPHONE** [1:4]$C_6H_4Me.SO_2.CHCl.CH_3$. [48°]. Formed by boiling $CH_3.CCl_2.CO_2Na$ (1 mol.) with $C_7H_7.SO_2Na$ (2 mols.) in aqueous solution. Formed also by heating ethylidene chloride (2·5 g.) with sodium toluene *p*-sulphinate (4·5 g.) and alcohol at 150° (Otto, *J. pr.* [2] 40, 515, 534). Trimetric tables, v. sol. hot alcohol. Does not act upon $C_7H_7.SO_2Na$ even at 200°.

p-**Tolyl chloro-ethyl sulphone** $C_6H_4Me.SO_2.CH_2.CH_2Cl$. [79°]. Formed from $C_6H_4Me.SO_2.CH_2.CH_2.OH$ and PCl_5 (Otto, *J. pr.* [2] 30, 357). Needles or plates, v. sol. hot alcohol.

p-**TOLYL CHLORO-METHYL SULPHONE** $C_6H_4Me.SO_2.CH_2Cl$. [84°]. Formed by heating an aqueous solution of $CHCl_2.CO_2Na$ (1 mol.) with $C_7H_7.SO_2Na$ (2 mols.) on the water-bath (Otto, *J. pr.* [2] 40, 528). Tables (from benzene), v. sol. hot alcohol.

p-**Tolyl di-chloro-methyl sulphone** $C_6H_4Me.SO_2.CHCl_2$. [114°]. Formed by passing chlorine into a warm aqueous solution of $C_7H_7.SO_2.CH_2.CO_2H$ (Otto, *J. pr.* [2] 40, 544). Crystals, insol. water, v. sol. hot alcohol.

TOLYL-CRESOL $C_6H_4Me.CH_2.C_6H_4.OH$. (250°–255° at 10 mm.). Formed by heating ω-chloro-xylene with phenol and zinc filings (Mazzara, *G.* 9, 421). Oil, sol. alcohol, ether, and alkalis. Not coloured by $FeCl_3$.

Acetyl derivative (250° at 9 mm.). Decomposed in moist air into HOAc and tolyl-cresol.

p-**TOLYL-CUMINYL-AMINE** $C_{17}H_{21}N$ *i.e.* $C_6H_4Me.NH.CH_2.C_6H_4Pr$. [36°]. (above 200°). Formed by the reduction by sodium-amalgam of the product of the action of cuminol on *p*-toluidine (Uebel, *A.* 245, 293). Plates or prisms.—B'HCl. Plates or needles, sl. sol. hot Aq.

Nitrosamine $C_{17}H_{20}N.NO$. [67°]. Prisms.

p-**TOLYL-CUMINYL-UREA** $C_{18}H_{22}N_2O$ *i.e.* $C_{10}H_{13}.NH.CO.NHC_6H_4Me$. [150°]. Formed from cuminylamine and *p*-tolyl cyanate (Goldschmidt a. Gessner, *B.* 22, 928). Needles, v. sol. alcohol.

p-**TOLYL-CUMYLIDENE-AMINE** $C_6H_4Me.N:CH.C_6H_4Pr$. [51°]. Formed from cuminic aldehyde (cuminol) and *p*-toluidine in alcoholic solution (Uebel, *A.* 245, 292). Yellowish plates (from alcohol). Decomposed into the parent substances by heating with acids and alkalis.

p-**TOLYL-ψ-CUMYL-UREA** $C_6H_4Me.NH.CO.NH.C_6H_2Me_3$. [218°]. Formed from ψ-cumidine and *p*-tolyl cyanate (Goldschmidt a. Bardach, *B.* 25, 1361). Needles.

o-**TOLYL-CYANAMIDE** $C_6H_4Me.NH.CN$. [77°]. Formed by heating $C_7H_7NH.CS.NH.OH$ or by the action of hydroxylamine on *o*-tolyl thiocarbimide (Tiemann, *B.* 22, 1940; Voltmer, *B.* 24, 881). Tables, v. sol. alcohol and KOHAq, m. sol. water.

DI-*o*-TOLYL-CYANAMIDE $C_{15}H_{14}N_2$ *i.e.* $C(NC_7H_7)_2$. *Carboditolylimide.* (above 300°). Formed by heating the alkyl derivatives of di-*o*-tolyl-thio-urea (Will a. Bielschowski, *B.* 15, 1317). Amorphous, v. sol. benzene. Converted by dilute HClAq into di-*o*-tolyl-urea.

Di-*p*-tolyl-cyanamide $C_{16}H_{14}N_2SO$ or $C(NC_7H_7)_2$. [60°]. (above 230°). Formed by the action of HgO on a benzene solution of di-tolyl-thio-urea (Will, *B.* 14, 1488). Thick prisms, sol. benzene and ether. On heating with aniline it gives phenyl-di-tolyl-guanidine. Acids and alkalis convert it into di-*p*-tolyl-urea. On distillation it yields compounds melting at 49° to 60° and at 149° (Schall a. Paschkowetzky, *B.* 25, 2892). Phenyl-hydrazine at 190° forms $C_{36}H_{36}N_8$ [163°], which crystallises from alcohol in plates, and yields B'_34HCl and $B'_32H_2PtCl_6$. On heating with phenyl-hydrazine at 165° there is formed $N_2PhH:C(NC_7H_7)_2$ [138°], crystallising in pale-red needles, yielding $B'_2H_2PtCl_6$ (Wessel, *B.* 21, 2274). Tolylene-*o*-diamine at 140° forms $C_{22}H_{24}N_4$ [196°], which yields B'_23HCl [143°] (Dahm a. Gasiorowski, *B.* 19, 3057).

TOLYL CYANATE *v.* Cyanic acid.

TOLYL CYANIDE *v.* *Nitrile* of Toluic acid.

TOLYL-CYANURIC ACID *v.* Cyanic acids.

TOLYLENE ALCOHOL *v.* Di-oxy-xylene.

TOLYLENE-DI-ALLYL-DI-THIO-DI-UREA [1:2:3] $C_6H_3Me(NH.CS.NHC_3H_5)_2$. [152°]. Formed from *c*-tolylene-*o*-diamine and oil of mustard (Lellmann, *A.* 228, 246). Needles (from alcohol), decomposed on fusing into tolylene-thio-urea and di-allyl-thio-urea.

Tolylene-di-allyl-di-thio-di-urea [1:3:4] $C_6H_3Me(NH.CS.NHC_3H_5)_2$. [150°]. Formed from *i*-tolylene-*o*-diamine and oil of mustard (Lellmann, *A.* 221, 24). Decomposed by heat like the preceding isomeride; melting a second time at 210°–230°.

Tolylene-di-allyl-di-thio-di-urea [1:2:5] $C_6H_3Me(NH.CS.NHC_3H_5)_2$. [175·5°]. Formed from tolylene-*p*-diamine and allyl thio-carbimide (Lellmann a. Würthner, *A.* 228, 209). Plates or prisms, nearly insol. ether.

Tolylene-di-allyl-di-thio-di-urea. [151°]. Formed from tolylene-*m*?-di-amine and allyl thiocarbimide. Prisms (from alcohol), insol. ether, v. sol. HOAc. Melts without decomposition.

TOLYLENE-DI-AMIDO-DI-ACETIC ETHER [1:2:4] $C_6H_3Me(NH.CH_2.CO_2Et)_2$. [70°]. Formed from tolylene-*m*-diamine and chloro-acetic ether (Zimmermann a. Knyrim, *B.* 16, 516). Needles (from water).

c-**TOLYLENE-*o*-DIAMINE** $C_7H_{10}N_2$ *i.e.* $C_6H_3Me(NH_2)_2$ [1:2:3]. Mol. w. 122. [62°]. (255°). Formed from $C_6H_3Me(NH_2)(NO_2)$ [1:2:3] by reducing with Sn and HCl (Lellmann, *A.* 228, 243). Reddish crystals, smelling of acetamide. —B''2HCl. Sol. water, ppd. by HCl.

c-**Tolylene-*m*-diamine** $C_6H_3Me(NH_2)_2$ [1:2:6]. [104°]. Formed by reduction of nitro-toluidine [92°], or of liquid di-nitro-toluene (Ullmann, *B.* 17, 1960). Prisms, sol. hot water. Gives a brown colour with nitrous acid. CrO_3 and $FeCl_3$ give a brown colour.—B'HCl: crystals, v. e. sol. water.

i-**Tolylene-*m*-diamine** $C_6H_3Me(NH_2)_2$ [1:2:4]. [99°]. (c. 280°). Formed by reducing di-nitro-toluene (Hofmann, *Pr.* 11, 518) by reducing (4,1,2)-nitro-toluidine (Nölting a. Collin, *B.* 17, 268), and by the action of $SnCl_2$ on amido-toluene-azo-amido-cresol (Graeff, *A.* 229, 348). Needles (from water), v. sol. alcohol, ether, and hot water. Chloroformic ether, $ClCO_2Et$, forms [1:2:4] $C_6H_3Me(NH_2)(NH.CO_2Et)$ [91°], and chiefly $C_6H_3Me(NH.CO_2Et)_2$ [137°] (Schiff, *A.* 268, 314). Phenyl-thio-carbimide yields $CO_2Et.NH.C_6H_3Me.NH.CS.NHPh$ [155°]. Heptoic aldehyde in the cold forms $C_7H_6N_2(C_7H_{14})_2$, but when heated it yields an orange mass which forms a highly fluorescent solution (Schiff a. Vanni, *A.* 253, 319). Benzoic aldehyde forms $C_7H_6(N{:}CHPh)_2$ [122°–128°], while cinnamic aldehyde gives $C_7H_6(NC_9H_8)_2$ [162°] (Schiff, *A.* 140, 98; 239, 384). $Cl.CO.CO_2Et$ forms $C_6H_3Me<\begin{matrix}NH.CO\\NH.CO\end{matrix}$ [c. 260°] and [1:2:4] $C_6H_3Me(NH_2).NH.CO.CO_2Et$ [170°], which yields an acetyl derivative [192°]. Phenyl-thiocarbimide forms the compound $NHPh.CS.NH.C_6H_3Me.NH.CO.CO_2Et$ [155°] and $C_6H_3Me<\begin{matrix}NH.CS\\NH.C_2O_2\end{matrix}>NPh$ [198°] (Schiff, *A.* 268, 307). Tolylene-*m*-diamine heated with citric acid at 125° forms $C_{13}H_{12}N_2O_5$, crystallising from boiling alcohol in minute octahedra, decomposing at about 187° (Schneider, *B.* 21, 665). Acetyl-acetone at 100° forms a syrup, which when heated with H_2SO_4 yields $C_{12}H_{14}N_2$ [191°] (Combes, *C. R.* 108, 1252).—$B''HCl$.—$B''2HCl$.—$B''2HBr$.—$B''H_2SO_4$ 2aq: prisms. S. 5·6 at 19·5 (Beilstein a. Kuhlberg, *A.* 158, 351).—$B''H_2PtCl_6$.—$B''2HCyS$. Prisms (Lussy, *B.* 7, 1265).

o-Acetyl derivative $C_6H_3Me(NHAc)NH_2$ [1:2:4]. [140°]. Formed from $C_6H_3Me(NH_2)(NO_2)$ [107°] by acetylation and reduction (Wallach, *A.* 234, 350). Needles.—$B'_2H_2PtCl_6$.

p-Acetyl derivative $C_6H_3Me(NH_2)(NHAc)$ [1:2:4]. [160°]. Formed by acetylating the diamine, and got also by reducing $C_6H_3Me(NO_2)(NHAc)$ [1:2:4] (Tiemann, *B.* 3, 221; Wallach, *B.* 15, 2826, 2831). Long white needles.

Di-acetyl derivative $C_6H_3Me(NHAc)_2$. [224°]. Got by boiling the base with Ac_2O or HOAc (Koch, *A.* 153, 132; Tiemann, *B.* 3, 8; Ladenburg, *B.* 8, 1211). Needles.

Benzoyl derivative $C_6H_3Me(NO_2)(NHBz)$ [1:2:4]. [142°]. Got by reducing $C_6H_3Me(NO_2)(NHBz)$ (Bell, *B.* 7, 1505).

Di-benzoyl derivative [224°]. Tables, sl. sol. alcohol (Ruhemann, *B.* 14, 2656).

Thiobenzoyl derivative $C_6H_3Me(NH_2)NH.CSPh$. [197°] (Bernthsen a. Trompetter, *B.* 11, 1760).

Phthalyl derivative $C_6H_3Me<\begin{matrix}NH.CO\\NH.CO\end{matrix}>C_6H_4$. [192°]. Formed from the base and phthalic anhydride (Biedermann, *B.* 10, 1161). Needles, split up by dilute HCl into phthalic acid and a base $C_{37}H_{31}N_6O_4$.

Di-phthalyl derivative $C_6H_3Me(NC_8H_4O_2)_2$. [233°]. Crystals, insol. water and alcohol.

***s*-Tolylene-*m*-diamine** $C_6H_3Me(NH_2)_2$ [1:3:5]. (284°). Formed by reducing *s*-di-nitro-toluene (Staedel, *A.* 217, 202). Syrup.—$B''H_2SO_4$.—$B''H_2SnCl_4$: crystals, v. sol. water.

Tolylene-*p*-diamine $C_6H_3Me(NH_2)_2$ [1:2:5]. [64°]. (274°). Formed by reducing (5,1,2)- and (2,1,5)- nitro-toluidines (Beilstein a. Kuhlberg, *A.* 158, 352; Fileti a. Crosa, *G.* 18, 306), and $C_6H_4Me.N_2.C_6H_3Me.NH_2$ [2:1:5] or [5:1:2] (Nietzki, *B.* 10, 832, 1158). Plates (from benzene), v. sol. water, alcohol, and ether. Forms toluquinone on oxidation. $FeCl_3$ added to a solution of tolylene-*p*-diamine hydrochloride mixed with *o*-toluidine gives an intense green colour.—$B''2HCl$. Plates.—$B''H_2SO_4$. S. ·84 at 11·5°.

Di-acetyl derivative $C_6H_3Me(NHAc)_2$. [220°]. Prisms (from dilute alcohol) (Nietzki, *B.* 10, 1157; 12, 2237).

Tolylene-*o*-diamine $C_6H_3Me(NH_2)_2$ [1:3:4]. [88·5°]. (265°). Formed by reducing (3 1,4)-nitro-*p*-toluidine (Beilstein a. Kuhlberg, *A.* 158, 351; Graeff, *A.* 229, 343). Plates, m. sol. cold water. Its aqueous solution quickly blackens when exposed to air. $FeCl_3$ forms by oxidation $C_{14}H_{13}N_3O$, crystallising from wood spirit in brownish-red plates [247°] (O. Fischer a. Sieder, *B.* 23, 3802).

Reactions.—1. *Benzoic aldehyde* at 140° forms $C_{21}H_{18}N_2$ or $C_7H_6<\begin{matrix}N(C_7H_7)\\N\end{matrix}>CPh$ [195·5°] (Ladenburg, *B.* 11, 591, 1656; Hinsberg, *B.* 19, 2026; 20, 1585), which yields $B'MeI$ [209°], $B'EtI$ [181°], and $B'EtI_3$ [125°], and is oxidised by $KMnO_4$ to an acid $C_{21}H_{16}N_2O_2$ [254°].—2. *Furfuraldehyde*, acting on the hydrochloride, forms $C_{17}H_{14}N_2O_2$ [128·5°], which yields $B'MeI$ [195·5°], $B'MeI_3$ [128°], and $B'MeI_5$ [109°].—3. *Acetic aldehyde* (2 mols.) added to a cold solution of the base (1 mol.) in glacial acetic acid forms $C_7H_6<\begin{matrix}NEt\\N\end{matrix}>CMe$ (Hinsberg).—4. *Anisic aldehyde*, added to a dilute aqueous solution of tolylene-*o*-diamine hydrochloride containing a little alcohol, forms $C_{23}H_{22}N_2O_2$ [152°–156°], which separates on addition of ammonia (L.).—5. *Salicylic aldehyde* at 110° forms $C_{28}H_{22}N_4O_3$ [106° 110°], and at 135° it forms azurine $C_{35}H_{32}N_4O_3$ [250·5°], which exhibits blue fluorescence in alkaline solutions.—6. *Glucose* (2 mols.) added to an alcoholic solution of tolylene-*o*-diamine forms $C_7H_6(N{:}C_6H_{12}O_5)_2$, crystallising in satiny needles, v. sol. water [c. 160°], which gives a red colour with $FeCl_3$. Glucose converts tolylene-*o*-diamine acetate into amorphous 'glycodiamido-toluene' $C_{13}H_{18}N_2O_5$, m. sol. water (Hinsberg, *B.* 20, 495; Griess a. Harrow, *B.* 20, 2209). Glucoson $C_6H_{10}O_6$ acts in aqueous solution on phenylene-*o*-diamine, forming $C_{13}H_{16}N_2O_4$ [c. 180°] (E. Fischer, *B.* 22, 93).—7. *Arabinose* forms $C_{12}H_{16}N_2O_4$ [238°] (G. a. H.).—8. *Acrolein* in boiling aqueous solution forms tolylene-*o*-diamine acroson [185°] (Fischer a. Tafel, *B.* 22, 99).—9. *Formic aldehyde* forms $C_{18}H_{20}N_4$ [222°] (Fischer a. Wrezinski, *B.* 25, 2713).—10. *Butyric aldehyde* forms tolylene-butenyl-diamine $C_7H_6<\begin{matrix}NH\\N\end{matrix}>CPr$ [158°], and the compound $C_{15}H_{22}N_2$ or $C_7H_6<\begin{matrix}N(C_4H_9)\\N\end{matrix}>CPr$ (Hinsberg, *B.* 20, 1590).—11. *Nitrous acid* or, better, amyl nitrite acting on a salt of tolylene-*o*-diamine forms azimido-toluene $C_7H_7N_3$ [84°] (323°), which is v. sol. alcohol and hot toluene (Zincke a. Lawson, *A.* 240, 115; *cf.* Ladenburg, *B.* 9, 220; Bössneck, *B.* 19, 1759; Nölting a. Abt, *B.* 20, 3001). Azimido-toluene forms the salts $B'_2H_2PtCl_6$, $NaC_7H_6N_3$, $Hg(C_7H_6N_3)_2$ [235°], and $AgC_7H_6N_3$. AcCl converts azimido-toluene into the (β)-acetyl derivative $C_7H_6{<}\substack{N\\N}{>}NAc$ [94°], while the isomeric (α)-acetyl derivative $C_7H_6{<}\substack{NAc\\N}{>}N$ [132°] is formed by the action of nitrous acid on the acetyl derivative of tolylene-o-diamine.—12. Boiling *chloro-acetic ether* forms oxytoluquinoxaline dihydride and a compound $C_{18}H_{16}N_2O_3$ (?) [147°], whence HNO_3 forms a compound [248°] (Hinsberg, *A.* 237, 365).—13. *Isatin* yields $C_{15}H_{11}N_3$ [290°], sl. sol. alcohol (Hinsberg, *A.* 237, 344).—14. Equal mols. of tolylene-o-diamine and *acetoacetic ether* when gently warmed together eliminate H_2O, and form a condensation product $C_{13}H_{18}N_2O_2$ [82°]; if this is heated at 100°–120° acetic ether is evolved, and a tolylene-ethenyl-o-diamine  $C_6H_3Me{<}\substack{NH\\N}{>}C.CH_3$ is produced (Ladenburg a. Rügheimer, *B.* 12, 953; Witt, *B.* 19, 2977, 3299).—15. *Chloro-aceto-acetic ether* forms $C_7H_6(NH)_2CMe.CHCl.CO_2Et$ [110°], crystallising in needles (Autenrieth a. Hinsberg, *B.* 25, 606).—16. *Oxydehydracetic acid* forms $C_8H_8O_5(C_6H_3Me(NH_2)_2)$ [147°] (Feist, *B.* 25, 325).—17. *o-Aldehydo-benzoic acid* in hot water forms  $C\,H_3Me{<}\substack{N\\NH}{>}C.C_6H_4.CO_2H$ [258°] (Bistrzycki, *B.* 23, 1043).—18. *Di-oxy-quinone* forms di-oxy-methyl-phenazine $C_{13}H_{10}N_2O_2$ [c. 265°], which yields a di-acetyl derivative [160°]. 19. *Opianic acid* gives, in alcoholic solution at 0°, the acid $C_6H_3Me:(N_2H):C.C_6H_2(OMe)_2.CO_2H$, crystallising in needles, decomposing at 234° (Bistrzycki, *B.* 24, 627).—20. *Di-bromo-pyruvic acid* (1 mol.) forms, on boiling,  $C_7H_6{<}\substack{N:C.CHBr_2\\N:C.OH}$ [235°].

Salts.—B''2HCl. Needles (Hübner, *A.* 209, 364).—$B''H_2SO_4$ 1½aq. Scales. S. 9·29 at 19·5°.—$B''2H_2C_2O_4$ aq (Hinsberg, *B.* 16, 1532).

Compound with pyrocatechin $B''C_6H_6O_2$. [78°]. Needles (from ligroïn) (Merz, *B.* 19, 726).

Compound with cyanogen $B''Cy_2$ aq. [c. 244°]. Formed by passing cyanogen into an alcoholic solution of the base (Bladin, *B.* 18, 666). Crystals, m. sol. alcohol and ether. Converted by heating with water into NH_3 and two isomeric compounds $C_9H_9N_3O$, one melting at 290°, the other beginning to decompose at 230°–240°. $B''Cy_2$ yields the salts $B''Cy_2HCl$ 1½aq, $B''Cy_22HCl$, $B''Cy_2H_2PtCl_6$ 2aq, minute needles, $(B''Cy_2)_2H_2PtCl_6$ 2aq, and $B''Cy_2H_2SO_4$ aq: minute tables.

p-Acetyl derivative
$C_6H_3Me(NH_2)(NHAc)$ [1:3:4]. [131°]. Formed by reducing $C_6H_3Me(NO_2)(NHAc)$ with iron and dilute HOAc (Boessneck, *B.* 19, 1757). Plates (from water). Converted by nitrous acid into acetyl-azimido-toluene. On distillation it yields tolylene-acetamidine $C_6H_3Me{<}\substack{N\\NH}{>}CMe$ [203°] (Niementowski, *B.* 25, 861).

Di-acetyl derivative $C_6H_3Me(NAcH)_2$. [216°]. Formed by boiling the base with Ac_2O (Bistrzycki, *B.* 23, 1878). Thin prisms (from water). Yields HOAc and tolylene-acetamidine on distillation.

Di-propionyl derivative
$C_6H_3Me(NH.CO.Et)_2$. [133°]. Formed in like manner (B.). Yields tolylene-propenyl-amine [166°] on distillation.

Benzoyl derivative
$C_6H_3Me(NH_2)(NHBz)$ [1:3:4]. [194°]. Formed by reduction of $C_6H_3Me(NO_2)(NHBz)$ with tin and HClAq (Hübner, *A.* 208, 314). Crystals, split up by distillation into water and tolylene-benzamidine [240°].

Di-benzoyl derivative $C_6H_3Me(NHBz)_2$. [264°]. Got by shaking tolylene-o-diamine with BzCl and NaOHAq (Hinsberg, *A.* 254, 255), by the action of Bz_2O on the diamine (Bistrzycki, *B.* 23, 1879; 24, 631), and by the action of BzCl on the benzoyl derivative (Hübner, *A.* 208, 314). Needles (from HOAc).

o-Chloro-benzoyl derivative
$C_6H_3Me(NH_2).NH.CO.C_6H_4Cl$. [153°] (Schreib, *B.* 13, 467). Converted by benzoyl chloride into $C_6H_3Me(NHBz).NH.CO.C_6H_4Cl$ [178°].

Di-cinnamyl derivative
$C_6H_3Me(NH.CO.C_8H_7)_2$. [206°]. Formed from tolylene-o-diamine and cinnamic anhydride (B.). Groups of small needles (from dilute alcohol).

Oxalyl derivative $C_2O_2(NH.C_7H_6.NH_2)_2$. [above 300°]. Obtained by the reduction of $C_2O_2(NH.C_7H_6.NO_2)_2$ (Hinsberg, *B.* 15, 2691). Small needles (from alcohol-ligroïn). On fusion it splits up into Aq and $C_{16}H_{14}N_4$ [193°].—Salts.—$B''H_2Cl_2$ aq.—$B''H_2PtCl_6$.—$B''H_2SO_4$ 5aq. Colourless needles.

Phthalyl derivatives.
The compounds $C_6H_3MeN_2H_2(C_8H_4O_2)$ [104°] and $C_6H_3Me(NC_8H_4O_2)_2$ [272°] are known (Biedermann, *B.* 10, 1165; Ladenburg, *B.* 10, 1125).

Benzene-sulphonyl derivative
$C_6H_3Me(NH_2).NH.SO_2Ph$. The hydrochloride, B'HCl, is formed by the action of benzene sulphonic chloride on tolylene-o-diamine in benzene (Bistrzycki a. Cybulski, *B.* 24, 633; *cf.* Lellmann, *A.* 221, 18).

Phenyl-acetyl derivative
$C_6H_3Me(NH_2).NH.CO.CH_2Ph$. [195°]. Formed from tolylene-o-diamine and phenylacetyl chloride (B. a. C.). Needles, v. sol. hot alcohol.

Di-phenylacetyl derivative
$C_6H_3Me(NH.CO.CH_2Ph)_2$. [176°]. Needles, insol. ether, v. sol. hot. alcohol.

References.—Bromo-, Chloro-, and Nitro-Tolylene-diamine.

TOLYLENE-DIAMINE SULPHINIC ACID *v.* Di-amido-toluene sulphinic acid.

TOLYLENE-*o*-DIAMINE SULPHONIC ACID $C_6H_2Me(NH_2)_2.SO_3H$ [1:2:3:5]. Formed by reducing nitro-toluidine sulphonic acid (Nietzki a. Pollini, *B.* 23, 139). Needles. Forms azines with o-diketones.

c-Tolylene-*m*-diamine sulphonic acid
$C_7H_{10}N_2SO_3$ *i.e.* $C_6H_2Me(NH_2)_2SO_3H$ [1:2:6:4]. S. ·07 at 14°. Formed from toluene *p*-sulphonic acid by nitration and reduction (Schwanert, *A.* 186, 360; Marckwald, *A.* 274, 349). Prisms, not melted at 280°.—BaA'_2 4aq.—HA'HCl 2aq.—HA'HBr 2aq.—$HA'HNO_3$ aq: needles, sl. sol. alcohol.—$(HA')_2H_2SO_4$ aq: plates.

Tolylene-*m*-diamine sulphonic acid
$C_6H_2Me(NH_2)_2.SO_3H$ [1:2:4:5]. S. ·1054 at 10°. Got by reduction of $C_6H_2Me(NO_2)(NH_2).SO_3H$ [1:2:4:5] with $SnCl_2$ (Limpricht a. Foth, *B.* 18, 2185; *A.* 230, 309). Small prisms.—KA' aq.—BaA'_2 5½aq.—HA'HCl aq.—HA'HBr aq: prisms,

Tolylene-*m* diamine sulphonic acid $C_6H_2Me(NH_2)_2.SO_3H$ [1:2:4:*x*]. Formed from tolylene-*m*-diamine and fuming H_2SO_4 (Wiesinger, *B.* 7, 464). Small prisms.—NaA′ 4aq.—KA′ aq.—MgA'_2 5aq.—CaA'_2 6½aq.—SrA'_2 7aq.—BaA'_2 6½aq.—MnA'_2 3aq.

TOLYLENE - DIAMINE THIOSULPHONIC ACID *v.* vol. i. p. 188.

TOLYLENE-BENZAMIDINE *v.* BENZENYL-TOLYLENE-DIAMINE.

TOLYLENE-BENZENYL-DIAMINE *v.* BENZENYL-TOLYLENE-DIAMINE.

***p*-TOLYLENE-BENZYL-DI-AMINE** [1:2:5] $C_6H_3Me(NH_2).NHCH_2Ph$. Got by reducing *p*-nitroso-benzyl-*o*-toluidine by alcoholic ammonium sulphide (Boeddinghaus, *A.* 263, 309).—B″2HCl. Needles, sl. sol. alcohol.

TOLYLENE BLUE $C_{15}H_{18}N_4HCl$. Formed by mixing solutions of nitroso-dimethyl-aniline hydrochloride and (1,2,4)-tolylene-*m*-diamine (Witt, *C. J.* 35, 358; *B.* 12, 931). Prisms (containing aq) with coppery lustre, forming blue solutions in water and alcohol. Acids turn the solutions reddish-brown. Alkalis pp. the base as a tarry mass. Tin and HClAq reduce it to the leuco- base, which forms a deliquescent hydrochloride and crystalline $(C_{15}H_{20}N_4)HSnCl_3$. On boiling tolylene-blue with water for some time part is reduced to leuco-tolylene blue and part oxidised to tolylene red $C_{15}H_{16}N_4$. Tolylene blue heated in aqueous solution containing HOAc for 12 hours at 40° forms tolylene violet $C_{14}H_{14}N_4$, characterised by an insoluble sulphate. Hydrated tolylene-violet $C_{14}H_{14}N_4$ aq is a scarlet powder which dissolves in alcohol and in ether, forming solutions with orange fluorescence.

Tolylene red

$$\left[1\begin{smallmatrix}3\\4\end{smallmatrix}\right] C_6H_3(NMe_2)\Big\langle\begin{smallmatrix}N\\N\end{smallmatrix}\Big\rangle C_6H_2Me(NH_2) \left[\begin{smallmatrix}3\\4\end{smallmatrix}:6:1\right]$$

(Bernthsen a. Schweitzer, *A.* 236, 332; Andresen, *B.* 19, 2217). Orange-red needles (containing 4aq). Forms a red fluorescent solution in alcohol. Its neutral salts are red, its acid salts are blue. By elimination of NH_2 by the diazo-reaction it is converted into di-methyl-amido-methyl-phenazine.

Isomeride of tolylene red

$$\left[1\begin{smallmatrix}3\\4\end{smallmatrix}\right] C_6H_3(NMe_2)\Big\langle\begin{smallmatrix}N\\N\end{smallmatrix}\Big\rangle C_6H_2Me(NH_2)\left[\begin{smallmatrix}3\\4\end{smallmatrix}5:1\right].$$

Formed from chloro-di-nitro-toluene and di-methyl-*p*-phenylene-diamine and reduction of the product (Witt, *B.* 25, 3008). Coppery needles, sol. warm water.

TOLYLENE-BUTENYL-DIAMINE *v.* BUTENYL-TOLYLENE-DIAMINE.

TOLYLENE-DICARBAMIC ETHER *v. i-*TOLYLENE-*m*-DIAMINE.

TOLYLENE DICYANATE $C_9H_6N_2O_2$ *i.e.* [1:2:4] $C_6H_3Me(N:CO)_2$. [94°]. Formed from tolylene *m*-diamine and $COCl_2$ (Snape, *C. J.* 49, 258). Needles, sol. ether. When heated with phenol at 130° it yields $C_6H_3Me(NH.CO_2Ph)_2$ [147·5°] crystallising in needles.

TOLYLENE-ETHENYL-DIAMINE $C_9H_{10}N_2$ *i.e.* $C_6H_3Me\Big\langle\begin{smallmatrix}N\\NH\end{smallmatrix}\Big\rangle CMe$. [203°] (Niementowski, *B.* 25, 861). (350°) (Nölting a. Witt, *B.* 17, 81). Formed by boiling (1,3,4)-tolylene-*o*-diamine with HOAc (Ladenburg, *B.* 8, 677) by reducing the acetyl derivative of nitro-*p*-toluidine (Hobrecker, *B.* 5, 920), and by adding aldehyde to a solution of tolylene-*o*-diamine in very dilute HOAc (Hinsberg, *B.* 20, 1589). Tables (from water). Forms with acetone and SO_2 the compound $(C_9H_{10}N_2C_3H_6O)SO_2$ (Boessneck, *B.* 21, 1909).—$B'_2H_2PtCl_6$.—$B'HNO_3$.

TOLYLENE-ETHENYL-ETHYL-DIAMINE $C_{11}H_{14}N_2$ *i.e.* $\begin{array}{l}CMe{:}CH.C.N\\CH\ {:}CH.C.NEt\end{array}\Big\rangle CMe$. [166°]. Formed from [1:3:4] $C_6H_3Me(NH_2).NHEt$ and Ac_2O (O. Fischer, *B.* 26, 200).

Tolylene-ethenyl-ethyl-diamine $\begin{array}{l}CMe{:}CH.C.NEt\\CH\ {:}CH.C.N\end{array}\Big\rangle CMe$. [93°]. Got by ethylation of tolylene-ethenyl-diamine (Hübner, *A.* 210, 351). Formed also by the action of aldehyde (2 mols.) on tolyene-*o*-diamine (1 mol.) (Hinsberg, *B.* 20, 1585) and by heating $C_6H_3Me(NO_2)NEtAc$ with zinc-dust and HOAc (Niementowski, *B.* 20, 1884). Needles (containing 3aq). Combines with ethyl iodide, forming B′EtI and $B'EtI_3$ [111°], which yield B′EtOH and $B'Et_2PtCl_6$. Salts.—K′HI aq [143°].—$B'HNO_3$ aq. [99°]. Melts at 95° when anhydrous.—$B'C_6H_3N_3O_7$. Crystals, sl. sol. alcohol.

TOLYLENE-ETHYL-DIAMINE $\begin{array}{l}CMe{:}CH.C.NH_2\\CH\ {:}CH.C.NHEt\end{array}$ [55°]. Formed by reduction of nitro-ethyl-*p*-toluidine (Gattermann, *B.* 18, 1184; Fischer, *B.* 26, 199). White plates, quickly blackened by light and air. Rotates on water.

Reactions.—1. Bisulphide of carbon yields $C_6H_3Me\Big\langle\begin{smallmatrix}N\\NEt\end{smallmatrix}\Big\rangle C.SH$ [139°].—2. Ac_2O forms tolylene-ethenyl-ethyl-diamine [166°].—3. Benzoic aldehyde yields $C_6H_3Me\Big\langle\begin{smallmatrix}N\\NEt\end{smallmatrix}\Big\rangle CPh$; while *o*- and *p*-nitro- and *o*-oxy- benzoic aldehydes from corresponding bodies [170°], [176°], and [78°].

Salts.—B′HCl. [176°].—$B'_2H_2C_2O_4$. [151°].

Tolylene-ethyl-diamine $C_6H_3Me(NHEt).NH_2$ [1:2:5]. (264° cor.). Formed by reducing nitroso-ethyl-*o*-toluidine (Koch, *A.* 243, 307). Oil, v. sol. ether.—B″2HCl. [124°]. Crystals, insol. ether.

Tolylene-ethyl-diamine $C_6H_3Me(NH_2)(NHEt)$ [1:2:4]. (282° uncor.). Formed by reduction of nitro-ethyl-*p*-toluidine (Nölting a. Stricker, *B.* 19, 549). Oil. Gives the reactions characteristic of *m*-diamines.

Tolylene-di-ethyl-diamine $C_6H_3Me(NHEt)_2$ [1:3:4]. (265° uncor.). Oil (Hinsberg, *A.* 265, 191). Turns black in air.

Tolylene-di-ethyl-diamine $C_6H_3Me(NEt_2)(NH_2)$ [1:2:5]. (240° i.V.). Formed by reducing nitro-di-ethyl-*o*-toluidine (Bernthsen, *B.* 25, 3138). Oil. $FeCl_3$ slowly gives a purple colour in an aqueous solution of the sulphate. $Na_2S_2O_3$ and $K_2Cr_2O_7$ added to its solution in HOAc slowly ppt. $SO_3H.S.C_6H_2Me(NEt_2)(NH_2)$ [210°-215°].—$B'H_2SO_4$. Large colourless tables.

DI-TOLYLENE-ETHYLENE-TETRA-AMINE *v.* ETHYLENE-DI-TOLYLENE-TETRA-AMINE.

TOLYLENE-DI-ETHYL-DI-THIO-DI-UREA [1:3:4] $MeC_6H_3(NH.CS.NHEt)_2$. [149°]. Got from ethyl mustard oil (5·5 g.) and tolylene-diamine (3 g.) in alcohol (15 c.c.) (Lellmann, *A.* 221, 23). V. sol. alcohol, more sol. HOAc, sl. sol. water. Decomposes when melted into tolylene-thio-urea, $Me.C_6H_3(NH)_2CS$, and $CS(NHEt)_2$.

(1.2.4)-Isomeride [225°]. Formed from tolylene-di-thio-di-urea and EtI at 105° (Lussy, *B.* 8, 668). Crystals.

TOLYLENE-DI-ETHYL-DI-UREA [1:2:4]$C_6H_3Me(NH.CO.NHEt)_2$. [175°]. Formed by heating tolylene-urea with EtI at 110° (Lussy, *B.* 8, 292). Crystals, v. sol. alcohol and ether.

TOLYLENE HYDRATE *v.* Phenyl-benzyl-carbinol.

DI-TOLYLENE KETONE OXIDE

$\left[1\begin{smallmatrix}3\\4\end{smallmatrix}\right]C_6H_3Me<\begin{smallmatrix}O\\CO\end{smallmatrix}>C_6H_3Me\left[\begin{smallmatrix}3\\4\end{smallmatrix}1\right]$. [166°]. Formed by heating oxytoluic acid with Ac_2O (Weber, *B.* 25, 1745). White flakes, sol. alcohol and ether.

TOLYLENE MERCAPTAN $C_6H_3Me(SH)_2$ [1:2:4]. *Dithiocresorcin.* [37°]. (263°) (Klason, *B.* 20, 355).

Di-tolylene mercaptan $HS.C_6H_3Me.C_6H_3Me.SH$. [113°]. Formed from the diazo- compound of di-amido-*o*-ditolyl by combination with potassium xanthate at 70°–75° and saponification of the resulting oil with alcoholic potash (Leuckart, *J. pr.* [2] 41, 214). Yellowish plates, v. sol. alcohol and ether.

Methyl ether [118°]. Needles.

TOLYLENE METHENYL-AMIDINE $C_8H_8N_2$ *i.e.* $C_6H_3Me<\begin{smallmatrix}N\\NH\end{smallmatrix}\gg CH$. [114°]. Formed by boiling from (1,3,4)-tolylene-diamine with formic acid (Ladenburg, *B.* 10, 1123; O. Fischer, *B.* 22, 644).—$B'_2H_2PtCl_6$. Yellow prisms.

TOLYLENE-METHENYL-DIAMINE *v.* Methenyl-tolylene-diamine and the preceding body.

TOLYLENE METHENYL - METHYL - DIAMINE $C_9H_{10}N_2$ *i.e.* $\begin{array}{l}CMe{:}CH.C.N\\CH\ {:}CH.C.NMe\end{array}\gg CH$. [94°]. Formed by heating $C_7H_6(NH_2).NHMe$ with formic acid (O. Fischer, *B.* 26, 195).

Isomeride $\begin{array}{l}CMe{:}CH.C.NMe\\CH\ {:}CH.C.N\end{array}\gg CH$. (279°). Formed by heating tolylene-methenyl-amidine with MeI (O. Fischer, *B.* 22, 644). Formed also from (1,3,4)-tolylene-diamine and formic aldehyde (Fischer a. Wreszinski, *B.* 25, 2711). Oil. —B'HI aq.—B'HCl. Prisms (from HClAq).

TOLYLENE-METHYL-DIAMINE [1:3:4] $C_6H_3Me(NH_2).NHMe$. [44°]. Formed by reducing nitro-methyl-*p*-toluidine (Gattermann, *B.* 18, 1487; O. Fischer, *B.* 26, 194). Formed also by heating methyl-*p*-amido-toluene-azo-benzene sulphonic acid with $SnCl_2$ and HClAq (Bamberger a. Wulz, *B.* 24, 2082). Four-sided tables.

Reactions.—1. *Acetic anhydride* yields $C_7H_6<\begin{smallmatrix}NH\\NMe\end{smallmatrix}\gg CMe$ [142°].—2. CS_2 reacts, forming $C_7H_6<\begin{smallmatrix}NH\\NMe\end{smallmatrix}>CS$ [194°].—3. *Benzoic aldehyde* forms $C_7H_6<\begin{smallmatrix}N\\NMe\end{smallmatrix}\gg CPh$ [127°], while *o*-nitro- and *o*-oxy-benzoic aldehyde form corresponding bodies [153°] and [180°].

Salts.—B'HCl. [175°-180°]. Plates (from alcohol).—$B'H_2C_2O_4$. [124°].—$B'C_6H_3N_3O_7$. [164°].

Tolylene-di-methyl-diamine $C_6H_3Me(NMe_2)(NH_2)$ [1:5:2]. [28°]. (270°). Formed by reducing nitroso-di-methyl-*m*-toluidine (Wurster a. Riedel, *B.* 12, 1801; 13, 126). Needles or prisms; v. sol. water, alcohol, and ether. Yields toluquinone on oxidation.

Acetyl derivative [158°].—$B'_2H_2PtCl_6$4aq.

Tolylene-di-methyl-diamine $C_6H_3Me(NMe_2)(NH_2)$ [1:2:5]. [47°]. (240° i.V.). Formed by reducing nitro-di-methyl-*o*-toluidine (Bernthsen, *B.* 25, 3134). $FeCl_3$ gives an intense bluish-red colour in neutral solutions. $Na_2S_2O_3$ and $K_2Cr_2O_7$ added to the acetic acid solution ppt. $C_6H_2Me(NMe_2)(NH_2)S.SO_3H$ [c. 240°]. **Salt.**—$B'_2H_2SO_4$. Needles, v. e. sol. water.

Tolylene-tetra-methyl-diamine $C_6H_3Me(NMe_2)_2$ [1:2:5]. (c. 260°). Formed by heating the preceding body with MeOH and HCl at 180° (W. a. R.). Liquid. Coloured blue in aqueous solution by $FeCl_3$.

Methylo-iodide B'MeI. [160°]. Needles.

Tolylene-tetra-methyl-diamine $C_6H_3Me(NMe_2)_2$[1:3:4]. (226°) at 717 mm. Got by methylation (Niementowski, *B.* 20, 1888). Liquid, v. sl. sol. water. $FeCl_3$ at 40° to 50° gives a reddish-brown colour. HNO_3 added to its solution in H_2SO_4 gives a red colouration.—$B'_2H_2PtCl_6$.—$B'HHgCl_3$.—$B'C_6H_3N_3O_7$. Yellow tables.

Reference.—Nitro-tolylene-tetra-methyl-diamine.

TOLYLENE-METHYL-ETHENYL-AMIDINE $C_{10}H_{12}N_2$ *i.e.* $\begin{array}{l}CMe{:}CH.C.N\\CH\ {:}CH.C.NMe\end{array}\gg CMe$. [142°]. Formed, together with $C_{10}H_{12}N_2O$ [163°], which crystallises with 2aq, by reducing the compound $C_6H_3Me(NO_2).NMeAc$ (Niementowski, *B.* 20, 1878), and by acting on tolylene-methyl-diamine with Ac_2O (O. Fischer, *B.* 26, 196). Needles (from hot water). $B'_2H_2PtCl_6$ (dried at 100°). [234°-244°].—B'HCl ½aq.—B'MeI. [221°]. —B'MeOH. [115°-135°].

TOLYLENE-TETRA-METHYL DI-PYRROLE TETRACARBOXYLIC ACID $C_{23}H_{22}N_2O_8$ *i.e.* [1:2:4]$C_6H_3Me\left(N<\begin{array}{l}CMe{:}C.CO_2H\\CMe{:}C.CO_2H\end{array}\right)_2$. [248°]. Sl. sol. hot alcohol and ether.

Ethyl ether Et_4A^{iv}. Formed by heating di-acetyl-succinic ether with tolylene-*m*-diamine and HOAc at 150° (Knorr, *A.* 236, 314). Oil.

TOLYLENE-METHYL-THIO-UREA $\begin{array}{l}CMe{:}CH.C.NH\\CH\ {:}CH.C.NMe\end{array}>CS$. [194°]. Formed from $C_7H_6(NH_2)(NHMe)$ and CS_2 (Fischer, *B.* 26, 196). Needles (from alcohol).

TOLYLENE-DI-OXAMIC ACID $C_{11}H_{10}N_2O_6$ *i.e.* $C_6H_3Me(NH.CO.CO_2H)_2$ [1:2:4]. Formed, together with the amide, by the action of alcoholic NH_3 on the ether. Crystalline. Very sweet. Decomposed by warm KOHAq into oxalic acid and tolylene-diamine.—Ag_2A''.—PbA''.—BaA'' 2aq.

Di-amide $C_6H_3Me(NH.CO.CONH_2)_2$[1:2:4]. Formed from the ether and alcoholic ammonia (Schiff, *A.* 268, 333). White powder, m. sol. alcohol.

Ethyl ether [1:2:4] $C_6H_3Me(NH.CO.CO_2Et)_2$. [130°]. Formed by boiling $C_6H_3Me(NH_2).NH.CO.CO_2Et$ with alcohol and oxalic ether (Schiff a. Vanni, *A.* 268, 340). Small needles (from ether).

Amide - ether $C_6H_3Me<\begin{array}{l}NH.CO.CO_2Et\\NH.CO.CO.NH_2\end{array}\left[1{:}\begin{smallmatrix}2\\4\end{smallmatrix}\right]$ [210°]. Formed from $C_6H_3Me(NH_2).NH.CO.CO.NH_2$ by boiling with alcohol and oxalic ether (Schiff, *A.* 268, 341).

Amide ether $C_6H_3Me{<}\begin{smallmatrix}NH.CO.CONH_2\\NH.CO.CO_2Et\end{smallmatrix}\left[1\begin{smallmatrix}2\\4\end{smallmatrix}\right]$ [c. 220°]. Got by fusing $C_6H_3Me(NH_2).NH.CO.CO_2Et$ with oxamic ether.

TOLYLENE-OXAMIDE $C_6H_3Me{<}\begin{smallmatrix}NH\\NH\end{smallmatrix}{>}C_2O_2$. [c. 260°]. Formed from (1,2,4)-tolylene-diamine and chloro-glyoxylic ether, and also by heating tolylene-diamine oxalate to 160° (Schiff a. Vanni, *A.* 268, 312).

TOLYLENE-PENTENYL-DIAMINE $\left[1\begin{smallmatrix}3\\4\end{smallmatrix}\right]$ $C_6H_3Me{<}\begin{smallmatrix}N\\NH\end{smallmatrix}{\gg}C.C_4H_9$. [116°]. Formed by reducing the valeryl derivative of nitro-*p*-toluidine (Friederici, *B.* 11, 1974; Hübner, *A.* 209, 365). Prisms (from ligroïn), v. e. sol. alcohol.

TOLYLENE - DI - PHENYL - DI - AMIDO-METHYLENE-DIAMINE $C_{20}H_{20}N_4$ *i.e.* $C_6H_3Me{<}\begin{smallmatrix}NH\\NH\end{smallmatrix}{>}C(NHPh)_2$. [161°]. Formed from $C(NPh)_2$ and (1,3,4)-tolylene-diamine at 130°-149° (Dahm a. Gasiorowski, *B.* 19, 3057). Needles (from benzene), v. sol. alcohol.—B'_23HCl. [171°].—$B'H_2SO_4$. Plates, v. sol. water and alcohol.

TOLYLENE-PROPENYL-DIAMINE $C_6H_3Me{<}\begin{smallmatrix}NH\\N\end{smallmatrix}{\gg}CEt$. [166°]. Formed by distilling the dipropionyl derivative of tolylene-*o*-diamine (Bistrzycki, *B.* 23, 1879). Needles, m. sol. water, almost insol. ligroïn.

TOLYLENE RED *v.* TOLYLENE BLUE.

DI-TOLYLENE DISULPHIDE $\begin{array}{l}CMe{:}CH.C.S.C.CH{:}CH\\ CH\ {:}CH.C.S.C.CH{:}CMe\end{array}$. [116°]. Formed by the action of heat at 200°-250° on tolylene diazo-sulphide $C_6H_3Me{<}\begin{smallmatrix}N\\S\end{smallmatrix}{\gg}N$ [43°], obtained from ethenyl-amido-tolyl mercaptan and HNO_2 (Jacobson a. Ney, *B.* 22, 911). Conc. H_2SO_4 gives an intense blue colour.

TOLYLENE - DI - THIO - DI - CARBAMIC ETHER [1:3:4] $C_6H_3Me(N{:}C(SH).OEt)_2$ [120°]. Formed by boiling tolylene-di-thiocarbimide with alcohol (Billeter a. Steiner, *B.* 20, 230). Plates (from benzene). Yields a yellowish-white silver salt.

TOLYLENE - DI - THIOCARBIMIDE [1:2:4] $C_6H_3Me(N.CS)_2$. [56°]. (c. 300°). Formed from tolylene-*m*-diamine and $CSCl_2$, and also by heating tolylene-di-thio-di-urea with conc. HClAq (Billeter a. Steiner, *B.* 18, 3292; 20, 230). Needles. Converted by NH_4Aq into tolylene-di-thio-di-urea [206°], by aniline into di-phenyl-tolylene-di-thio-di-urea [168°]. Copper at 250° produces $C_6H_3MeCy_2$ [141°].

Tolylene-di-thiocarbimide [1:3:4] $C_6H_3Me(N.CS)_2$. [42°]. Formed from an aqueous solution of tolylene-*o*-diamine hydrochloride and $CSCl_2$ in $CHCl_3$ (B. a. S.). Plates. Converted by HCl at 200° into *o*-tolylene-thio-urea.

TOLYLENE-DI-THIO-DIGLYCOLLIC ACID $C_6H_3Me(S.CH_2.CO_2H)_2$. [152°]. Formed from thio-orcin $C_6H_3Me(SH)_2$ [35°], chloro-acetic acid, and NaOHAq (Gabriel, *B.* 12, 1640). Needles, m. sol. hot Aq.

TOLYLENE THIO-UREA $C_6H_3Me{<}\begin{smallmatrix}NH\\NH\end{smallmatrix}{>}CS$. Formed from $C_6H_3Me(NH_2HCl)_2$ [1:2:3] and excess of NH_4SCN by boiling with water, evaporating, and heating to 120° (Lellmann, *A.* 228, 245). Small red crystals (from alcohol). Does not melt below 326°; may be sublimed. Insol. water, sl. sol. alcohol, dissolved by warm NaOH; re-ppd. by HCl. When boiled with lead acetate and excess of NaOH, no PbS is formed.

Tolylene - thio - urea $C_6H_3Me{<}\begin{smallmatrix}NH\\NH\end{smallmatrix}{>}CS$. [284°]. Formed by heating (1,3,4)-tolylene-*o*-diamine sulphocyanide at 130° (Lellmann, *A.* 221, 10]. Formed also by the action of alcoholic NH_3 on *o*-tolylene di-thiocarbimide (Billeter a. Steiner, *B.* 20, 231). Silvery plates, sol. alcohol, HOAc, and cold NaOHAq, sl. sol. water and $CHCl_3$.

m-**Tolylene - thio - urea** $C_6H_3Me{<}\begin{smallmatrix}NH\\NH\end{smallmatrix}{>}CS$. [119°]. Formed from (1,2,4)-tolylene-diamine and alcoholic CS_2 (Lussy, *B.* 8, 293). Crystalline powder, v. e. sol. alcohol.

m-**Tolylene-di-thio-di-urea** [1:2:4] $C_6H_3Me(NH.CS.NH_2)_2$. [218°] (L.); [200°] (B. a. S.). Formed by heating tolylene-*m*-diamine sulphocyanide (Lussy, *B.* 7, 1265; Gebhardt, *B.* 17, 3046; Billeter a. Steiner, *B.* 18, 3293; 20, 228). Crystalline powder, insol. water and ether, nearly insol. alcohol, m. sol. hot HOAc.

TOLYLENE-TOLENYL-AMIDINE $C_{15}H_{14}N_2$ *i.e.* $C_6H_3Me{<}\begin{smallmatrix}NH\\N\end{smallmatrix}{\gg}C.C_6H_4Me$. Formed by reducing [1:4] $C_6H_4Me.CO.NH.C_6H_3(NO_2)Me$ [4:3:1] (Hübner, *A.* 210, 331). Needles, sl. sol. water.—$B'HCl$.—$B'HNO_3$.—$B'_2H_2SO_4$. Crystals, sl. sol. water.

TOLYLENE - DI - *p* - TOLYL - DI - AMIDO-METHYLENE-DIAMINE $C_{22}H_{24}N_4$ *i.e.* $C_6H_3Me{<}\begin{smallmatrix}NH\\NH\end{smallmatrix}{>}C(NH.C_6H_4Me)_2$. [196°]. Formed by heating $C(NC_6H_4Me)_2$ with (1,3,4)-tolylene-diamine (Dahm a. Gasiorowski, *B.* 19, 3059). Needles (from alcohol).—B'_23HCl. [143°]. Deliquescent needles, v. sol. water.

TOLYLENE-TOLYL-DIAMINE $C_{14}H_{16}N_2$ *i.e.* [1:3:4] $C_6H_3Me(NH_2)NHC_6H_4Me$ [1:4]. *Amido-di-p-tolyl-amine.* [109°]. Formed by reducing nitro-di-*p*-tolylamine (O. Fischer, *B.* 23, 3798; 26, 187). Prisms (from ligroïn), turning brownish-red in air. H_2SO_4 forms a blue solution changing to green. $FeCl_3$ forms $C_{28}H_{27}N_5O$ [188°] crystallising in red plates, yielding $B'_2H_2PtCl_6$. Boiling with acetic anhydride and sodium acetate produces $C_7H_6{<}\begin{smallmatrix}N(C_7H_7)\\N\end{smallmatrix}{\gg}CMe$ [95°], which forms $B'_2H_2PtCl_6$. Benzoic aldehyde forms $C_7H_6{<}\begin{smallmatrix}N(C_7H_7)\\NH\end{smallmatrix}{>}CHPh$ [156°], which yields $(C_{21}H_{20}N_2)_2H_2PtCl_6$ and $C_{21}H_{20}N_2HAuCl_4$.

Salts.—$B'H_2C_2O_4$. Nearly insol. cold Aq.—$B'C_6H_3N_3O_7$. Brownish-red crystals.

Acetyl derivative [126°]. Prisms.

Tolylene-*p*-tolyl-diamine [1:4:3] $C_6H_3Me(NH_2).NHC_6H_4Me$ [1:4]. [107°]. Formed from toluene-azo-toluene or *s*-di-*p*-tolyl-hydrazine (hydrazo-toluene) in alcoholic solution by the action of $SnCl_2$ and HCl (Täuber, *B.* 25, 1022; *cf.* Melms, *B.* 8, 554; Goldschmidt, *B.* 11, 1626). Plates, v. e. sol. alcohol. $NaNO_2$ colours its solution in H_2SO_4 deep blue (?). Benzoic aldehyde reacts, forming

$C_7H_6\left<\begin{matrix}N(C_7H_7)\\N\end{matrix}\right>CPh$ [165°] (*cf.* Lellmann, *B.* 15, 832). Benzil in alcohol and HCl forms $C_{28}H_{24}N_2O$ [173°]. Ethyl nitrite and H_2SO_4 added to its alcoholic solution form the azimide $C_7H_6\left<\begin{matrix}N(C_7H_7)\\N\end{matrix}\right>N$ [93°]. On oxidation together with *p*-toluidine it forms the ditoluide of amido-toluquinone (Green, *C. J.* 63, 1408).

Tolylene-di-*p*-tolyl-diamine [1:2:5] $C_6H_3Me(NHC_7H_7)_2$. [113°]. Formed by heating hydrotoluquinone (40 g.) with *p*-toluidine (160 g.) and $ZnCl_2$ (80 g.) to 200°–280° for 5 hours (Green, *C. J.* 63, 1408). Plates, sol. HOAc, insol. water.

TOLYLENE-*p*-TOLYL-GUANIDINE $C_6H_3Me\left<\begin{matrix}NH\\NH\end{matrix}\right>C:NC_7H_7$. [198°]. Formed from tolylene-*o*-diamine and $C(NC_7H_7)_2$ (Keller, *B.* 24, 2518). Prisms (from alcohol), or tables (from benzene). Phenyl cyanate forms the compound $C_7H_6\left<\begin{matrix}N\\N\end{matrix}\right>C:NC_7H_7\left<\begin{matrix}CO\\CO\end{matrix}\right>NPh$ [233°], crystallising from hot alcohol in needles.—B'HCl.—$B'_2H_2PtCl_6$.—$B'_2H_2SO_4$ 5aq. Needles, sl. sol. cold water.

Acetyl derivative $C_7H_6\left<\begin{matrix}NAc\\NH\end{matrix}\right>C:NC_7H_7$. [149°]. Needles, v. sol. alcohol.

Di-benzoyl derivative [201°]. Needles.

Nitrosamine $C_7H_6:N_2H(NO):C:NC_7H_7$. [c. 140°]. Decomposed on fusion.

TOLYLENE-*p*-TOLYL-THIO-UREA $\left.\begin{array}{l}CH:CH.C.N(C_7H_7)\\CMe:CH.C.NH\end{array}\right>CS$. [270°]. Formed from tolylene-tolyl-diamine and CS_2 in alcohol (Fischer a. Sieder, *B.* 23, 3799). Prisms, insol. water, sl. sol. ligroïn. Conc. H_2SO_4 forms a green solution.

TOLYLENE-UREA $C_8H_8N_2O$ *i.e.* $\left[1:\begin{matrix}3\\4\end{matrix}\right]C_6H_3Me\left<\begin{matrix}NH\\NH\end{matrix}\right>CO$. [292°]. Formed by heating tolylene-*o*-diamine with urea and got also by the action of HClAq at 140° on $C_6H_3Me\left<\begin{matrix}NH\\N\end{matrix}\right>C.OEt$ [163°], which is formed by the action of $HN:C(OEt)_2$ on tolylene-*o*-diamine hydrochloride (Sandmeyer, *B.* 19, 2651). Formed also by heating $C_7H_6(NH_2).NH.CO.NPh_2$ (Lellmann a. Bonhöffer, *B.* 20, 2124) or the compound $C_7H_6(NH_2).NH.CO.NHPh$ (Leuckart, *J. pr.* [2] 41, 324, who states that it melts above 300°), and by heating tolylene-*o*-diamine in benzene with $COCl_2$ in toluene in sealed tubes at 100° (Hartmann, *B.* 23, 1048). Needles, sl. sol. hot water.—B'HCl: prisms.

TOLYLENE-DI-UREA $C_9H_{12}N_4O_2$ *i.e.* [1:3:4] $C_6H_3Me(NH.CO.NH_2)_2$. [282°]. Got from tolylene-diamine hydrochloride and potassium cyanate in aqueous solution (Lellmann, *A.* 228, 14). Needles, sl. sol. water and chloroform, sol. alcohol and hot conc. HCl; v. sol. HOAc.

Tolylene-di-urea $C_9H_{12}N_4O_2$ *i.e.* [1:2:4] $C_6H_3Me(NH.CO.NH_2)_2$. [220°]. Formed from tolylene-*m*-diamine sulphate and KCyO (Strauss, *A.* 148, 157). Formed also from tolylene cyanate and ammonia (Lussy, *B.* 8, 291). Scales, sl. sol. alcohol and hot water.—B''2HCl.

TOLYLENE-VIOLET *v.* TOLYLENE BLUE.

***s*-DI-TOLYL-ETHANE** $C_6H_4Me.CH_2.CH_2.C_6H_4Me$. (296°). Formed from $C_6H_4Me.CH_2Cl$ and sodium (Vollrath, *Z.* 1866, 489). Oil.

***u*-Di-*p*-tolyl-ethane** $CH_3.CH(C_6H_4Me)_2$. (295°). S.G. $\frac{20}{4}$ ·974. Formed by shaking paraldehyde with toluene and H_2SO_4 at 0° (O. Fischer, *B.* 7, 1191). Formed also by heating di-α-tolyl-propionic acid with lime (Haiss, *B.* 15, 1476) and by the action of ethylidene chloride and $AlCl_3$ on toluene (Anschütz, *B.* 18, 664; *A.* 235, 315). Oil. Yields toluyl-benzoic acid and di-tolyl ketone on oxidation.

***s-mp*-Di-tolyl-ethane** $C_2H_4(C_7H_7)_2$. (297°–300°). Formed from ethylene bromide, toluene, and $AlCl_3$ (Friedel a. Balsohn, *Bl.* [2] 35, 52; *A. Ch.* [6] 1, 487). Yields isophthalic and terephthalic acids on oxidation.

References.—AMIDO-, CHLORO-, TRI-CHLORO-, DI-NITRO-, and OXY-TOLYL-, ETHANES.

TOLYL ETHER *v.* DI-TOLYL OXIDE.

***o*-TOLYL-ETHYL ALCOHOL.** *Hexahydride* $CH_2\left<\begin{matrix}CH_2.CHMe\\CH_2.CH_2\end{matrix}\right>CH.CHMe.OH$. (195°–200°). Formed, together with the tetrahydride $CH_2\left<\begin{matrix}CH_2.CMe\\CH_2.CH_2\end{matrix}\right>C.CHMe.OH$ (142° at 50 mm.) by reducing $C_6H_8Me.CO.CH_3$ in moist ethereal solution by sodium (Kipping a. Perkin, jun., *C. J.* 57, 22). Oil. Yields an acetyl derivative (204°–208°).

***p*-TOLYL-ETHYL-*m*-AMIDO-PHENOL.** *Ethyl derivative* $C_7H_7.NEt.C_6H_4.OEt$. Formed from $C_7H_7.NH.C_6H_4.OH$, potash, and EtI (Hatschek a. Zega, *J. pr.* [2] 33, 217). Oil.

***p*-Tolyl-ethyl-*p*-amido-phenol.** *Ethyl derivative* $C_{17}H_{21}NO$ *i.e.* $C_7H_7.NEt.C_6H_4.OEt$. (c. 340°). From $C_7H_7.NH.C_6H_4.OH$, potash, and EtI (H. a. Z.). Oil.

TOLYL-ETHYL-AMINE *v.* ETHYL-TOLUIDINE.

Di-tolyl-ethyl-amine $(C_6H_4Me)_2NEt$. (255°–260° at 20 mm.). Formed by heating di-*p*-tolyl-amine with EtOH and HCl at 250°–280° (Girard, *Bl.* [2] 24, 120). Oil.

***o*-TOLYL ETHYL CARBONATE** $C_{10}H_{12}O_3$ *i.e.* [1:2] $C_6H_4Me.O.CO.OEt$. (236°). Formed from sodium *o*-cresol and $ClCO_2Et$ (Bender, *B.* 13, 700). Oil.

***m*-Tolyl ethyl carbonate.** (246°). Formed in like manner from *m*-cresol. Oil.

***p*-Tolyl ethyl carbonate.** (245°). Oil. By long heating at 300° it yields di-*p*-tolyl carbonate and di-ethyl carbonate (Bender, *B.* 19, 2268).

DI-*p*-TOLYL-ETHYLENE $C_{16}H_{16}$ *i.e.* $C_6H_4Me.CH:CH.C_6H_4Me$. *Di-methyl-stilbene.* [179°]. (above 300°). Formed by distilling $(C_6H_4Me)_2CH.CCl_3$ with zinc-dust (Goldschmiedt a. Hepp, *B.* 6, 1504; Elbs a. Förster, *J. pr.* [2] 39, 300), and by heating di-*p*-tolyl fumarate, CO_2 being evolved (Anschütz, *B.* 18, 1948). Plates, v. sol. $CHCl_3$. Yields a dibromide [204°].

***u*-Di-tolyl-ethylene** $CH_2:C(C_6H_4Me)_2$. (305°). Formed by the action of alcoholic potash on $CH_2Cl.CH(C_7H_7)_2$ (Hepp, *B.* 7, 1413). Oil. Yields di-tolyl-ketone [94°] on oxidation.

Tetra-tolyl-ethylene $C_{30}H_{28}$ *i.e.* $(C_7H_7)_2C:C(C_7H_7)_2$. [215°]. A product of the action of chloroform and $AlCl_3$ on toluene (Schwarz, *B.* 14, 1529). Plates, with greenish-yellow fluorescence, sol. benzene.

References.—BROMO- and DI-CHLORO- TOLYL-ETHYLENE.

o-TOLYL-ETHYLENE-DIAMINE $C_7H_7NH.C_2H_4.NH_2$. (c. 267°). Formed from o-tolylamido-ethyl-phthalimide and HCl (Newman, *B.* 24, 2194). Sol. water and alcohol.—$B''2HCl$. [168°–173°].—$B''2C_6H_3N_3O_7$. [148°]. Green needles.

Di-benzoyl derivative [164·5°]. Needles.

p-Tolyl-ethylene-diamine. Formed in like manner (N.). Liquid.—$B''2HCl$. [218°].—$B''H_2PtCl_6$. Yellowish plates.

Di-acetyl derivative [107°]. Needles.

Di-benzoyl derivative [161°]. Cubes.

Di-o-tolyl-ethylene-diamine $C_{16}H_{20}N_2$ *i.e.* $C_7H_7NH.CH_2.CH_2.NHC_7H_7$. [71°]. S. ·3 at 100°. S. (cold alcohol) 9. S. (ether) 14. Formed by the action of o-toluidine on ethylene bromide in presence of Na_2CO_3 (Bischoff, *B.* 23, 1982, 2031; 25, 3257; *cf.* Mauthner a. Suida, *M.* 7, 230; Colson, *Bl.* [2] 48, 799). Plates (from ligroïn), v. sol. alcohol. Yields indole on heating with zinc-dust. $CH_2Cl.CO_2H$ and NaOAc from di-tolyl-pyrazine hexahydride [154°].—$B''2HCl$.—$B''H_2PtCl_6$.—$B''H_2SO_4$ (dried at 100°).—$B''2HBr$. [222°]. S. 3 at 100°.

Acetyl derivative $C_2H_4(NAc.C_7H_7)_2$. [153°].

Bromo-acetyl derivative $C_2H_4(NC_7H_7.CO.CH_2Br)_2$. [205°]. Sl. sol. cold HOAc and ligroïn.

Bromo-propionyl derivative $C_{22}H_{26}N_2Br_2O_2$. [181°].

Bromo-n-butyryl derivative $(C_{24}H_{30}N_2Br_2O_2)C_6H_6$ (from benzene). [190°].

Bromo-isobutyryl derivatives $C_7H_7NH.C_2H_4.NC_7H_7.CO.CBrMe_2$ [137°] and $C_{24}H_{30}N_2Br_2O_2$ [173°].

Di-p-tolyl-ethylene-diamine [97·5°]. Formed by heating p-toluidine with ethylene bromide at 150° (Gretillat, *M. S.* [3] 3, 383; Bischoff, *B.* 25, 3260). Crystals, v. e. sol. alcohol.—*Hydrobromide* [255°].

Acetyl derivative $C_2H_4(NAc.C_7H_7)_2$. [139°].

Bromo-acetyl derivative $C_{20}H_{22}N_2Br_2O_2$. [196°].

Bromo-propionyl derivative. [182°].

Bromo-n-butyryl derivative $C_{24}H_{30}N_2Br_2O_2$. [125°].

Bromo-isobutyryl derivative $C_{24}H_{30}N_2Br_2O_2$. [175°].

Di-o-tolyl-di-ethylene-diamine $C_{18}H_{22}N_2$. [171°]. Formed, together with di-o-tolyl-ethylene-diamine, by heating o-toluidine with $C_2H_4Br_2$ (M. a. S.). Needles, sl. sol. alcohol. Forms indole when distilled with zinc-dust.

Di-p-tolyl-di-ethylene-diamine [190°]. (360°). Formed by heating $C_2H_4Cl.OH$ with p-toluidine at 220° (Wurtz, *A. Suppl.* 7, 94; Demole, *A.* 173, 138). Prisms, v. sl. sol. alcohol.—$B''H_2PtCl_6$.

Tri-p-tolyl-tri-ethylene-triamine $N_3(C_7H_7)_3(C_2H_4)_3$. [186°]. Formed by heating p-toluidine with $C_2H_4Br_2$ (G.). Needles, v. sl. sol. alcohol. Is perhaps identical with the preceding body. Its hydrochloride melts at 189°.

Reference.—NITRO-DI-TOLYL-ETHYLENE-DIAMINE.

p-TOLYL ETHYLENE ETHYL DIOXIDE $C_6H_4Me.O.CH_2.CH_2.OEt$. (244°). Formed from $C_7H_7.O.C_2H_4Br$ and alcoholic potash (Schreiber, *B.* 24, 195).

DI-p-TOLYL ETHYLENE DIKETONE $C_{18}H_{18}O_2$ *i.e.* $C_2H_4(CO.C_6H_4Me)_2$. *Di-toluyl-ethane.* [159°]. Formed by the action of succinyl chloride and $AlCl_3$ on toluene (Hollemann, *R. T. C.* 6, 70; Claus, *B.* 20, 1877). Needles, v. sl. sol. cold alcohol, insol. alkalis. AcCl converts it into di-p-tolyl-furfurane $C_{18}H_{16}O$ [164°]. Ammonium acetate and HOAc on boiling form di-p-tolyl-pyrrole [197°]. P_2S_5 forms di-p-tolyl-thiophene [171°].

DI-p-TOLYL-ETHYLENE-DI-METHYL-DI-AMINE $C_{18}H_{24}N_2$ *i.e.* $C_2H_4(NMe.C_6H_4Me)_2$. [80°]. Formed by boiling its di-methylo-di-bromide with NH_3Aq (Hübner, *A.* 224, 337). Tables or prisms (from alcohol), v. sl. sol. water.—$B''H_2HgCl_4$. [190°].—$B''H_2PtCl_6$. Orange-yellow powder.

Methylo-iodide $B''MeI$. Needles. Decomposed at 100°. M. sol. hot water.

Methylo-bromide $B''2MeBr$. Formed by heating di-methyl-p-toluidine with $C_2H_4Br_2$ at 105° for some days. Yields $B''Me_2Hg_2Cl_6$ [159°–162°], $B''Me_2SnCl_6$, $B''Me_2PtCl_6$, and $B''2C_6H_2MeN_3O_7$ [197°], which crystallises from alcohol.

TOLYL ETHYLENE OXIDE *v.* ETHYLENE ETHER OF CRESOL.

DI-p-TOLYL ETHYLENE DISULPHONE $(C_7H_7.SO_2)_2C_2H_4$. [201°]. Made by boiling sodium toluene p-sulphinate with $C_2H_4Br_2$ and alcohol (Otto, *J. pr.* [2] 30, 351; 40, 534). Got also by boiling the same salt with $CH_3.CCl_2.CO_2Na$. Needles or plates. Dilute KOHAq converts it into toluene sulphinic acid and $C_7H_7.SO_2.C_2H_4.OH$ [55°], which yields $C_7H_7.SO_2.C_2H_4Cl$ [79°], $C_7H_7.SO_2.C_2H_4I$ [100°], $C_7H_7.SO_2.C_2H_4OBz$ [176°] and $(C_7H_7.SO_2.C_2H_4)_2S$ [150°–160°]. Ammonia forms $(C_7H_7.SO_2.C_2H_4)_2NH$, which yields a hydrochloride [201°].

DI-p-TOLYL-ETHYLENE-UREA $\begin{matrix}CH_2.N(C_7H_7)\\CH_2.N(C_7H_7)\end{matrix}\Big>CO$. [228°]. Formed from di-p-tolyl-ethylene-diamine and $COCl_2$ (Michler a. Keller, *B.* 14, 2181). Needles.

p-TOLYL-DI-ETHYL-PHOSPHINE $C_7H_7.PEt_2$. (240°). Formed from $C_7H_7PCl_2$ and $ZnEt_2$ (Czimatis, *B.* 15, 2016). Liquid.—$B'MeI$. [137°].—$B'_2Me_2PtCl_6$. Yellow plates.

p-TOLYL ETHYL SULPHONE $C_7H_7.SO_2.C_2H_5$. [56°]. Formed by oxidation of $C_7H_7.SEt$ and by the action of EtBr on sodium toluene p-sulphinate (Otto, *B.* 13, 1276; 18, 161). Formed also by warming the acid $C_7H_7.SO_2.CHMe.CO_2H$ with KOHAq. Trimetric plates; $a:b:c$ = ·526:1:·721. Sol. alcohol and ether.

p-TOLYL ETHYL SULPHONE α-CARBOXYLIC ACID $C_7H_7.SO_2.CHMe.CO_2H$. *Tolyl-sulphono-propionic acid.* [37°]. Formed by heating $C_7H_7.SO_2Na$ with $CH_3.CHBr.CO_2Et$ and alcohol at 150° and saponifying the product (Otto, *J. pr.* [2] 40, 555). Crystals (from alcohol), converted by Cl into $CH_3.CHCl.SO_2.C_7H_7$.

TOLYL ETHYL DISULPHOXIDE *v.* *Ethyl ether* of TOLUENE THIOSULPHONIC ACID.

TOLYL ETHYL THIOBIURET $C_{11}H_{15}N_3S_2$. [134°]. Formed from tolyl-thiobiuret, alcohol, aqueous NH_3, and EtI (Tursini, *B.* 17, 585). Needles (from alcohol).

o-TOLYL-ETHYL-THIOSEMICARBAZIDE $C_7H_7NH.NH.CS.NHEt$. [180°]. Formed o-tolyl-hydrazine and an alcoholic solution of ethyl-thiocarbimide (Dixon, *C. J.* 57, 262). Needles, v. sl. sol. cold water. $CuSO_4$ colours its alcoholic solution deep blue.

TOLYL ETHYL DI-THIO-CARBONATES $CS(OEt).S.C_6H_4Me$. The *o*-, *m*-, and *p*- compounds formed by the action of potassium xanthate on cold solutions of *o*-, *m*-, and *p*-diazotoluene chloride are oils (Leuckart, *J. pr.* [2] 41, 188). They are converted into tolyl mercaptans by boiling with alcoholic potash.

***o*-TOLYL-ETHYL-THIO-UREA** $CS(NHEt).NHC_6H_4Me$. [84°]. Formed from *o*-tolyl-thiocarbimide and ethylamine (Staats, *B.* 13, 136). Prisms, insol. water, sol. alcohol and ether.

***p*-Tolyl-ethyl-thio-urea** [96°]. Formed in like manner (Weith, *B.* 8, 1530). Tables, v. sol. hot water.

***o*-Tolyl-di-ethyl-thio-urea** $CS(NEt_2).NHC_7H_7$. [102°]. Formed from *o*-tolyl-thiocarbimide and $NHEt_2$ (Gebhardt, *B.* 17, 3038). Needles or prisms.

***p*-TOLYL-ETHYL-TOLUTRIAZINE DIHYDRIDE** $C_{17}H_{19}N_3$ *i.e.*  $C_6H_3Me<\begin{smallmatrix}N.CHEt\\N.N.C_6H_4Me\end{smallmatrix}$. [168°]. Formed by heating toluene-azo-toluidine with propionic aldehyde at 140° (Goldschmidt a. Poltzer, *B.* 24, 1009). Needles (from hot benzene).—B'HCl. [96°].—Platinochloride [221°]. Small yellow needles.

***p*-TOLYL-ETHYL-UREA** $C_{10}H_{14}N_2O$ *i.e.* $NHC_7H_7.CO.NHEt$. Formed from *p*-toluidine and ethyl cyanate (Sell, *A.* 126, 162). Crystals, insol. water, v. e. sol. alcohol.

DI-*o*-TOLYL-FORMAMIDINE $C_{15}H_{16}N_2$ *i.e.* $NHC_7H_7.CH:NC_7H_7$. [151°]. Formed by boiling the formyl derivative of *o*-toluidine for a long time, or by heating it with *o*-toluidine and PCl_3 (Ladenburg, *B.* 10, 1260). Formed also by distilling the thioformyl derivative of *o*-toluidine *in vacuo* (Senier, *C. J.* 47, 762). Prisms (from alcohol), insol. dilute NaOHAq. Yields crystalline $C_{15}C_{16}N_2Br_2$.—$B'_2H_2PtCl_6$.

Di-*m*-tolyl-formamidine $NHC_7H_7.CH:NC_7H_7$. [123°]. Formed by boiling *m*-toluidine with formic acid (Niementowski, *B.* 20, 1893). Needles or plates, insol. water. Br in CS_2 yields crystalline $NHC_7H_7.CHBr.NBrC_7H_7$.—B'HCl. [214°].—$B'_2H_2PtCl_6$.—$B'C_6H_3N_3O_7$. Yellow needles.

Di-*p*-tolyl-formamidine [141°]. Formed by distilling $C_7H_7NH.CHS$ *in vacuo* (Senier, *C. J.* 47, 767; *B.* 18, 2296). Prisms.—$B'_2H_2PtCl_6$.

DI-*p*-TOLYL-FURFURANE $C_{18}H_{16}O$ *i.e.*  $\begin{smallmatrix}CH:C(C_7H_7)\\CH:C(C_7H_7)\end{smallmatrix}>O$. [164°]. Formed by the action of AcCl on $C_2H_2(CO.C_7H_7)_2$ (Holleman, *R. T. C.* 6, 72). Small plates, converted by P_2S_5 into di-tolyl-thiophene, and by ammonium acetate into di-tolyl-pyrrole.

***p*-TOLYL-GLYOXAL** $C_6H_4Me.CO.CHO$. [102°]. Formed from the oxim by dissolving in aqueous $NaHSO_3$, stirring the crystalline mass with alcohol and a little HOAc, filtering, and boiling with dilute H_2SO_4 (Müller a. Pechmann, *B.* 22, 2556). Needles (from hot water), v. sol. alcohol. Reduces cold ammoniacal $AgNO_3$, but not Fehling's solution. When shaken with benzene (containing thiophene) and H_2SO_4 it colours the benzene green. Yields *p*-tolyl-glyoxylic acid and *p*-toluic acid on oxidation.

Phenyl hydrazide $C_7H_7.C(N_2HPh).CH(N_2HPh)$. [145°]. Yellow needles (from dilute alcohol).

Oxim $C_7H_7.CO.CH:NOH$. *Tolyl nitroso-methyl ketone.* [100°]. Formed from tolyl methyl ketone, amyl nitrite and NaOEt. Needles (from benzene).

Acetyl derivative of the syn-oxim $C_7H_7.CO.CH:NOAc$ [68°]. From the oxim and Ac_2O (Söderbaum, *B.* 25, 3461). Tables (from MeOH). Cold NaOHAq splits it up into NaCy and *p*-toluic acid. Conc. H_2SO_4 acts in like manner. Ac_2O at 100° forms $C_7H_7.CO.CN$ [52°], whence boiling NaOHAq forms *p*-toluic acid.

Acetyl derivative of the anti-oxim $C_7H_7.C(OH)_2.CH:NOAc$. [148°]. From the oxim and AcCl at 0°, followed by water. Cold NaOHAq forms $C_7H_7.CH(OH).CO_2H$ [146°], v. sol. ether. Conc. H_2SO_4 converts this acetyl *anti*-oxim into the oxim. Converted by KCy dissolved in dilute alcohol into *p*-toluyl-formoïn $C_7H_7.CO.CH(OH).CO.CO.C_7H_7$ [161°] (Söderbaum, *B.* 25, 3473).

***p*-TOLYL-GLYOXALINE** $C_{10}H_{10}N_2$ *i.e.*  $C_7H_7N<\begin{smallmatrix}CH:CH\\CH:N\end{smallmatrix}$. (285°). Got by warming  $C_7H_7N<\begin{smallmatrix}CH=CH\\C(SH):N\end{smallmatrix}$ with dilute HNO_3 (Marckwald, *B.* 25, 2365). Pale-yellow crystals, sl. sol. water. Smells like mushrooms.—$B'_2H_2PtCl_6$.—$B'AgNO_3$.—Picrate. [179°]. Golden needles.

***p*-TOLYL-GLYOXALYL MERCAPTAN**  $C_7H_7N<\begin{smallmatrix}CH=CH\\C(SH):N\end{smallmatrix}$. [205°]. Got by action of boiling HClAq on the product of the action of amido-acetal on *p*-tolyl thiocarbimide (Marckwald, *B.* 25, 2363). Silvery leaflets, m. sol. hot water. Yields $(C_{10}H_{10}N_2S)_2PtCl_4$. MeI in alcohol forms $(C_{10}H_9MeN_2S)HI$ [95°], which yields the base  $C_7H_7N<\begin{smallmatrix}CH=CH\\C(SMe):N\end{smallmatrix}$ [90°], which forms a picrate [140°].

***p*-TOLYL-GLYOXYLIC ACID** $C_9H_8O_3$ *i.e.* $C_6H_4Me.CO.CO_2H$. [97°]. Formed by the action of $AlCl_3$ on a mixture of toluene and $Cl.CO.CO_2C_5H_{11}$ (Roser, *B.* 14, 1750). Formed also by oxidising *p*-tolyl methyl ketone with cold alkaline K_3FeCy_6 (Buchka a. Irish, *B.* 20, 1762, 2213). Needles (from ligroïn), sl. sol. hot water, v. sol. alcohol and ether. Yields *p*-toluic and terephthalic acids on oxidation. Benzene (containing thiophene) when shaken with tolyl-glyoxylic acid and H_2SO_4 is turned red, and finally bluish-violet.

Salts.—KA'.—NaA' ½aq (Claus a. Kroseberg, *B.* 20, 2018).—BaA'_2.—$BaA'_2$8aq.—CaA'_2aq.—AgA'. Needles, v. sol. hot water.

Ethyl ether EtA'. (260°–270°).

Amide $C_9H_9NO_2$. [160°]. Prisms.

Phenyl hydrazide [144°].

DI-*o*-TOLYL-GUANIDINE $C_{15}H_{17}N_3$ *i.e.* $C(NH)(NHC_7H_7)_2$. [179°]. Formed by the action of NH_3, lead acetate, and KOHAq on di-*o*-tolyl-thio-urea (Berger, *B.* 12, 1855). Crystals, sol. ether. Cyanogen passed into its alcoholic solution forms the dicyanide $C_{17}H_{17}N_5$ [174°] which is converted by HCl into the oxalyl derivative $C_{17}H_{15}N_3O_2$ [207°], whence boiling with alcoholic HCl forms  $CO<\begin{smallmatrix}NC_7H_7.CO\\NC_7H_7.CO\end{smallmatrix}$. [214°]. The dicyanide is converted by boiling with ani-

line into $C_{22}H_{21}N_5$, which yields crystalline $B'HCl$ aq.—$B'_2H_2PtCl_6$: yellow pp.

Di-*p*-tolyl-guanidine $NH.C(NHC_7H_7)_2$. [168°]. Formed by passing cyanogen chloride into fused *p*-toluidine (W. Wilson, *C. J.* 8, 154; A. G. Perkin, *C. J.* 37, 696). Formed also by desulphuration of di-tolyl-thio-urea in presence of NH_3 (Hofmann, *B.* 7, 1739). Needles (from ligroïn). Nitric acid (S.G. 1·5) gives a di-nitro-derivative [197°], which forms crystalline $B'HNO_3$. Alcohol and HNO_3 (S.G. 1·4) produce di-nitro-*p*-tolyl-urea. Cyanogen passed into its ethereal solution forms $C_{15}H_{17}N_3Cy_2$, crystallising from ether in prisms, converted by dilute HClAq into  $NH.C{<}\begin{matrix}N(C_7H_7).CO\\N(C_7H_7).CO\end{matrix}$ [188·5°] (Landgrebe, *B.* 10, 1587). The cyanide is converted by boiling in alcoholic solution with aniline hydrochloride into $C_{23}H_{21}N_5\frac{1}{2}$aq [110°–115°].—**Salt** $B'_2H_2PtCl_6$.

Tri-*o*-tolyl-guanidine $C_{22}H_{23}N_3$ *i.e.* $C(NC_7H_7)(NHC_7H_7)_2$. [131°]. Formed by the action of *o*-toluidine in alcoholic solution in presence of lead oxide on di-*o*-tolyl-thiourea (Berger, *B.* 12, 1857; *cf.* Girard, *B.* 6, 445). Formed also when di-*o*-tolyl-thiourea is boiled for a long time (Barr, *B.* 19, 1769). Minute prisms. Yields a dicyanide $C_{24}H_{23}N_5$ [141°], converted by conc. HClAq in alcoholic solution into $C_{24}H_{21}N_3O_2$ [179°].—$B'_2H_2PtCl_6$: yellow prisms.

Tri-*p*-tolyl-guanidine $C_{22}H_{23}N_3$. [123°]. S. (alcohol) 7·4 at 0°. Formed by heating di-*p*-tolyl-thio-urea with copper (Merz a. Weith, *Z.* 1868, 610), or, in alcoholic solution, with *p*-toluidine and PbO (Hofmann, *B.* 2, 459). Got by heating *p*-toluidine with PCl_3 and *p*-tolyl cyanate (Weith, *B.* 9, 820). Formed also when di-*p*-tolyl-urea is boiled for a long time (Barr, *B.* 19, 1768), and likewise by the action of *p*-toluidine on the product of the action of chlorine on tolyl cyanate (Nef, *A.* 270, 322). Needles (from ligroïn). Yields a dicyanide $C_{24}H_{21}N_5$ [184°], which forms $B'HCl3$aq and $B'_2H_2PtCl_6$ and is converted by boiling with alcoholic HCl into di-tolyl-parabanic acid.

Salts.—$B'HCl$ aq. S. ·6 at 0°.—$B'_2H_2PtCl_6$. S. ·045 at 0°.—$B'HNO_3$. S. ·07 at 0°.—$B'_2H_2SO_4$. Plates (from hot water). Neutral in reaction.

***p*-TOLYL HEPTADECYL KETONE** [1:4]$C_6H_4Me.CO.C_{17}H_{35}$. [67°]. (278° at 15 mm.). Formed from toluene, stearyl chloride, and $AlCl_3$ (Krafft, *B.* 21, 2268). Oxidised by HNO_3 (S.G. 1·12) to *p*-toluic acid.

***p*-TOLYL-HEXYL-TOLUTRIAZINE DIHYDRIDE** $C_{21}H_{27}N_3$ *i.e.*  $C_6H_3Me{<}\begin{matrix}N.CH.C_6H_{13}\\N.N.C_6H_4Me\end{matrix}$. [165°]. Formed by heating œnanthol with toluene-*o*-azo-toluidine at 175° (Goldschmidt a. Poltzer, *B.* 24, 1010). Needles, sol. hot benzene.—BHCl. [96°].—$B'_2H_2PtCl_6$. [171°]. Yellow crystalline pp.

***o*-TOLYL-HYDANTOÏN** $C_{10}H_{10}N_2O_2$. [176°]. Formed by heating *o*-tolyl-amido-acetic acid with urea at 180° (Ehrlich, *B.* 16, 742). Light-yellow plates, sol. alcohol and hot water. On boiling with baryta-water it gives *o*-tolyl-hydantoïc acid, which, when set free from its salts, at once splits up into water and *o*-tolyl-hydantoïn.

***p*-Tolyl-hydantoïn** $C_{10}H_{10}N_2O_2$ *i.e.*  $CO{<}\begin{matrix}NH\text{——}CO\\N(C_7H_7).CH_2\end{matrix}$. [210°]. Formed, together with *p*-tolyl-hydantoic acid $CO(NH_2).N(C_7H_7).CH_2.CO_2H$, by fusing *p*-tolyl-amido-acetic acid with urea (Schwebel, *B.* 11, 1128). Needles (from water), v. sol. alcohol. ***p*-Tolyl-hydantoic acid** is crystalline, sl. sol. hot alcohol and hot water.

Di-*o*-tolyl-hydantoïn  $CO{<}\begin{matrix}N(C_7H_7).CO\\N(C_7H_7).CH_2\end{matrix}$. [275°]. Got from *o*-tolyl-amido-acetic toluide and $COCl_2$ (Bischoff, *B.* 25, 2275).

Di-*p*-tolyl-hydantoïn  $CO{<}\begin{matrix}N(C_7H_7).CO\\N(C_7H_7).CH_2\end{matrix}$. [175°]. Formed from *p*-tolyl-amido-acetic toluide and $COCl_2$ (Bischoff, *B.* 25, 2280). Plates (from alcohol), sl. sol. ligroïn.

TOLYL-HYDRAZIDO-METHYL-THIAZOLE DIHYDRIDE $\begin{matrix}CHMe.S\\CH_2\text{—}N\end{matrix}{>}C.NH.NHC_7H_7$. Formed by heating tolyl-allyl-thio-semicarbazide with conc. HClAq at 100° (Avenarius, *B.* 24, 270). The *p*- compound melts at 133°. Both the *o*- and the *p*- compounds form crystalline hydrochlorides.

***o*-TOLYL-HYDRAZIDO-PROPIONIC ACID** $C_6H_4Me.NH.NH.CHMe.CO_2H$. [143°]. Formed by the action of sodium-amalgam on the *o*-tolyl-hydrazide of pyruvic acid (Japp a. Klingemann, *C. J.* 53, 519). Small needles (from MeOH).

***o*-TOLYL-HYDRAZINE** $C_7H_7NH.NH_2$. [53°] (P.); [56°] (F.); [59°] (Gallinek a. Richter, *B.* 18, 3175). Prepared from *o*-toluidine in the same manner as phenyl-hydrazine is obtained from aniline (Fischer a. Bösler, *A.* 212, 338; Freund, *B.* 24, 4200). Glittering plates, slowly oxidised by air, forming a brown oil.—$B'HCl$ aq: needles.—$B'HNO_3$: plates. With $SOCl_2$ and ether it forms $C_7H_7NH.N{:}SO$, a yellow oil smelling like geraniums (Michaelis, *A.* 270, 119). Glucose yields *o*-tolyl-glucosazone $C_{20}H_{26}N_4O_4$ [201°] (Raschen, *A.* 239, 229). Di-methyl di-ketone forms $CH_3.C(N_2HC_7H_7).C(N_2HC_7H_7).CH_3$ [198°] (Japp a. Klingemann, *A.* 247, 221).

Formyl derivative $C_6H_4Me.NH.NHCHO$. [121°]. Formed from *o*-tolyl hydrazine and formamide. Needles (Gattermann, *B.* 25, 1078).

Acetyl derivative $C_7H_7.NH.NHAc$. [104°]. Formed from *o*-tolyl-hydrazine and Ac_2O (G.).

Propionyl derivative $C_7H_7.NH.NH.C_3H_5O$. [84°]. Formed from *o*-tolyl-hydrazine and propionic acid (G.). Colourless tables.

Benzoyl derivative $C_7H_7.NH.NHBz$. [180°]. Got from the hydrazine and BzCl in Et_2O (G.). Needles. Gives off all its nitrogen in the free state on boiling with Fehling's solution (Strache a. Iritzer, *M.* 14, 38).

***m*-Tolyl-hydrazine** $C_7H_7.NH.NH_2$. (242°) (Buchka a. Schachtebek, *B.* 22, 841; *cf.* V. Meyer a. Lecco, *B.* 16, 2976). Oil.—$B'HCl$. Needles, v. sol. water and alcohol.

***p*-Tolyl-hydrazine** $C_7H_7NH.NH_2$. [61°]. (242°). Obtained from *p*-toluidine (Fischer, *B.* 8, 589; 9, 890). White plates (from ether), sl. sol. water.

Reactions.—1. With $SOCl_2$ and ether it forms $C_7H_7NH.N{:}SO$ [112°], crystallising in yellow needles (Michaelis a. Ruhl, *A.* 270, 118).—2. $C_6H_5PCl_2$ forms $C_7H_7NH.N{:}PC_6H_5$ [162°], crystallising in prisms.—3. $POCl_3$ forms $(C_7H_7NH.NH)_3PO$ [189°].—4. *Acetone* forms $CMe_2(N_2HC_7H_7)$ [52°].—5. *Acetoacetic ether* forms $C_{13}H_{18}N_2O_2$ [93°] (Knorr, *B.* 17, 550).—6. *Oxalic ether* forms $NHC_7H_7.NH.CO.CO_2Et$. [133°] (Preund, *B.* 24, 4198).—7. *Di-methyl diketone* yields $CH_3.C(N_2HC_7H_7).C(N_2HC_7H_7).CH_3$ [230°], and $CH_3.C(N_2HC_7H_7)Ac$ [161°] (Japp, *C. J.* 53, 544).

Salt.—$B'C_6H_5PH_2O_2$. [148°] (Michaelis, *A.* 270, 134).

Toluene-*p*-phosphinate $B'C_7H_7PH_2O_2$. [161°].

Formyl derivative $C_6H_4Me.NH.NH.CHO$. [164°]. Formed by heating the alcoholic solution of *p*-tolyl-hydrazine with chloroform and potash. Formed also by heating *p*-tolyl-hydrazine with formamide at 130° (Ruhemann, *C. J.* 55, 248). Plates (from water), v. sol. alcohol.

Acetyl derivative $C_6H_4Me.NH.NHAc$. [121°]. Formed from *p*-tolyl-hydrazine and AcOH (Gattermann, *B.* 25, 1080). Plates.

Propionyl derivative [170°]. Needles.

Dibenzoyl derivative [188°] (Fischer).

Di-*o*-tolyl-hydrazine.

Formyl derivative $(C_7H_7)_2N.NH.CHO$. [139°]. Formed from $C_7H_7NH.NH.CHO$ and $CuSO_4$ (Gattermann, *B.* 25, 1078). Plates.

Acetyl derivative $(C_7H_7)_2N.NHAc$. [191°]. Formed in like manner from acetyl-*o*-tolyl-hydrazine and $CuSO_4$. Needles.

Propionyl derivative [167°]. Needles.

Benzoyl derivative [209°]. Needles.

***u*-Di-*p*-tolyl-hydrazine** $(C_7H_7)_2N.NH_2$. [172°]. Formed by reduction of di-tolyl-nitrosamine with zinc-dust and HOAc (Lehne, *B.* 13, 1546). Plates, v. sol. alcohol and benzene.—B'HCl.

Formyl derivative $(C_7H_7)_2N.NH.CHO$. [146°]. Formed from formyl-*p*-tolyl-hydrazine and $CuSO_4$ (Gattermann, *B.* 25, 1079). Plates.

Acetyl derivative. [176°]. Needles.

Propionyl derivative [171·5°]. Needles.

Benzoyl derivative. [187°]. Needles.

***s*-Di-*o*-tolyl-hydrazine** $C_7H_7NH.NHC_7H_7$. *o-Hydrazo-toluene.* [165°] (P.); [146°] (S.). Formed by reduction of *o*-toluene-azo-toluene by sodium amalgam (Petrieff, *B.* 6, 557; Schultz, *B.* 17, 467). Converted into di-amido-ditolyl $[3:4:1]C_6H_3Me(NH_2).C_6H_3Me(NH_2)[1:3:4]$ [128°] by heating with HCl. The diamido-derivative $C_7H_6(NH_2).NH.NH.C_7H_6(NH_2)$ [180°] is a product of the action of sodium-amalgam on nitro-*p*-toluidine (Buckney, *B.* 11, 1453).

***s*-Di-*m*-tolyl-hydrazine** $C_7H_7NH.NHC_7H_7$. Formed by reducing *m*-toluene-*m*-azo-toluene by alcoholic ammonium sulphide (Goldschmidt, *B.* 11, 1626; Barsilowsky, *A.* 207, 116). Liquid, converted by H_2SO_4 into di-amido-ditolyl.

***s*-Di-*p*-tolyl-hydrazine** $C_7H_7NH.NHC_7H_7$. [126°]. Formed in like manner from *p*-toluene-*p*-azo-toluene (Melms, *B.* 3, 553) and by the action of zinc-dust and NaOHAq on *p*-nitro-toluene (Janovsky, *M.* 9, 829). Tables or needles, v. e. sol. alcohol. In alcoholic solution it is readily oxidised by air to $C_7H_7.N_2.C_7H_7$. Dilute H_2SO_4 converts it into toluidine and toluene-azo-toluene. On treatment in alcoholic solution with hydrochloric acid it changes to tolylene-tolyl-diamine. The di-amido-derivative $[1:2:4]C_6H_3Me(NH_2).NH.NH.C_6H_3Me(NH_2)[4:1:2]$ obtained from $C_6H_3Me(NH_2).N_2.C_6H_3Me(NH_2)$ by reducing with sodium-amalgam, is crystalline and yields $B''H_2SO_4$, $B''2HCl$, $B''2HBr$, and $B''H_2PtCl_6$ (Graeff, *A.* 229, 352).

Reference.—OXY-TOLYL-HYDRAZINE.

***o*-TOLYL-HYDRAZINE SULPHONIC ACID** $C_6H_3Me(N_2H_3).SO_3H$ [1:2:4]. Formed by adding *o*-diazo-toluene *p*-sulphonic acid to a cold solution of $SnCl_2$ (Limpricht, *B.* 18, 2193). Colourless needles, v. sol. hot water, nearly insol. alcohol.—KA′ 2aq: orange-red prisms.—BaA'_2: yellow crystalline powder.

***o*-Tolyl-hydrazine sulphonic acid** $C_6H_3Me(N_2H_3).SO_3H$ [1:*x*:2]. Formed by heating *o*-tolyl-hydrazine (1 pt.) with conc. H_2SO_4 (5 pts.) at 100° (Gallinck a. Richter, *B.* 18, 3175). Thin needles (containing ½aq). By boiling with aqueous $CuSO_4$ it is quantitatively decomposed into a toluene sulphonic acid and nitrogen.—NaA′ 3½aq.—BaA'_2 4aq.—ZnA'_2 3aq.—PbA'_2 6aq.—$Pb_3A'_2(OH)_4$. Sparingly soluble needles.

***p*-Tolyl-hydrazine-*o*-sulphonic acid** $C_6H_3Me(N_2H_3).SO_3H$ [1:4:2]. [274°]. Formed by reducing *p*-diazo-toluene *o*-sulphonic acid with Na_2SO_3 (Brackett a. Hayes, *Am.* 9, 401) or HCl and $SnCl_2$ (Pasche, *B.* 21, 3416). Tables, sl. sol. cold water. Decomposed by fusion. Not attacked by warm H_2SO_4.

***p*-Tolyl-hydrazine *m*-sulphonic acid** $C_6H_3Me(N_2H_3).SO_3H$ [1:3:4]. Obtained by reducing *p*-diazotoluene *m*-sulphonic acid by cooled $SnCl_2$ (Limpricht, *B.* 18, 2193). Slender prisms, sol. hot water. $FeCl_3$ evolves nitrogen in the cold. Conc. H_2SO_4 at 80° forms a red amorphous substance (Schneider, *Am.* 8, 271).

***p*-Tolyl-hydrazine disulphonic acid** $C_6H_2Me(N_2H_3)(SO_3H)_2$. Formed by adding *p*-diazo-toluene disulphonic acid to a cold solution of $SnCl_2$ (Limpricht, *B.* 18, 2193). Nodules, v. sol. water.—$BaH_2A''_2$ 2½aq: tables.

Di-tolyl-hydrazine disulphonic acid $C_6H_3Me(SO_3H).NH.NH.C_6H_3Me(SO_3H)$. A product of the reduction of the corresponding azo-compound by $SnCl_2$ (Neale, *A.* 203, 72). Crystalline powder (containing 2½aq), sl. sol. water.—BaA″ 5aq.—CaA″ 3½aq: monoclinic efflorescent prisms.

Reference.—NITRO-TOLYL-HYDRAZINE SULPHONIC ACID.

***o*-TOLYL-IMIDO-DIACETIC ACID** $[1:2]C_6H_4Me.N(CH_2.CO_2H)_2$. [c. 160°]. Formed by heating *o*-tolyl-amido-acetic acid (1 mol.) with chloro-acetic acid (1 mol.), Na_2CO_3 (1½ mols.) and a little water at 140° (Bischoff, *B.* 23, 1994; 25, 2270). White crystals, insol. ligroïn, sl. sol. ether, m. sol. alcohol.—NH_4A'. [160°]. V. sol. Aq.

Amide $C_7H_7N(CH_2.CO.NH_2)_2$. [164°]. Plates.

Di-o-toluide $C_7H_7N(CH_2.CO.NHC_7H_7)_2$. [150°].

Imide 
$C_7H_7N\left<\begin{matrix}CH_2.CO\\CH_2.CO\end{matrix}\right>NH$. [146°]. Prisms (from alcohol), sl. sol. water.

o-Tolylamic acid $C_7H_7N(CH_2.CO_2H).CH_2.CO.NHC_7H_7$. [148°]. Crystals (from alcohol).

***p*-Tolylimido-diacetic acid** $[1:4]C_6H_4Me.N(CH_2.CO_2H)_2$. *Diglycotolylamic acid.* [c. 140°]. Formed by the action of $CH_2Cl.CO_2H$ on *p*-tolyl-glycocoll (Meyer, *B.* 14, 1323; Bischoff, *B.* 23, 2000). Needles (from water). Very unstable. — CuA'_2 aq: green needles.—$Ag_2A'(NO_3)$: needles.—*p*-Toluidine

salt $(C_7H_7NH_2)HA'$. [119°]. Crystals, sol. hot water.

Mono-amide. [222°]. A product of the action of Ac_2O on the compound [168°] got from chloro-acetic acid and *p*-toluidine (Bischoff, *B.* 25, 2280).

Di-amide $C_7H_7N(CH_2.CO.NH_2)_2$. [250°].

Di-p-toluide $C_7H_7N(CH_2.CO.NHC_7H_7)_2$. [251°]. Long needles (from alcohol).

Amide p-toluide $C_7H_7N(CH_2.CO.NH_2)CH_2.CO.NHC_7H_7$. [210°].

p-Tolylamic acid $C_7H_7N(CH_2.CO_2H).CH_2.CONHC_7H_7$. [222°]. Needles, insol. water, sol. hot alcohol.

***p*-TOLYL-IMIDO-DIACRYLIC ETHER** $C_6H_4MeN(CH:CH.CO_2Et)_2$. [73°]. Formed from *p*-toluidine and formyl-acetic ether (Von Pechmann, *B.* 25, 1053). Yellow needles (from dilute alcohol).

***o*-TOLYL-β-IMIDO-BENZYL-MALONIC ETHER** $C_{21}H_{23}NO_4$ *i.e.* $C_6H_5.C(NC_7H_7).CH(CO_2Et)_2$. [95°]. Formed by the action of ω-chloro-benzylidene-*o*-toluidine upon sodium-malonic ether (Just, *B.* 19, 985). Crystals, v. sol. ether. Split up by dilute HClAq at 120° into acetophenone and *o*-toluidine. The *p*-isomeride is liquid.

***o*-TOLYL-β-IMIDO-BUTYRIC ACID** $C_6H_4Me.N:CMe.CH_2.CO_2H$. [112°]. Formed by heating acetoacetic ether with *o*-toluidine at 150° (Knorr, *B.* 17, 542; Pawlewski, *B.* 22, 2203). Needles (from hot water), converted by conc. H_2SO_4 into (*Py.* 1)-oxy-(*B.* 4, *Py.* 3)-di-methyl-quinoline.

p-**Tolyl-β-imido-butyric acid.** Formed in like manner from *p*-toluidine. Crystals. Converted by H_2SO_4 into (*Py.* 1)-oxy-(*B.* 2, *Py.* 3)-di-methyl-quinoline.

***p*-TOLYL IODO-ETHYL SULPHONE** $C_7H_7.SO_2.CH_2.CH_2I$. [100°]. Formed from tolyl oxy-ethyl sulphone and HIAq at 160° (Otto, *J. pr.* [2] 30, 357). Crystals, v. sol. hot alcohol.

TOLYL IODO-METHYL SULPHONE $C_7H_7.SO_2.CH_2I$. [126°]. Formed by heating sodium toluene sulphinate with CH_2I_2 and alcohol (Otto, *B.* 21, 655). Small needles, v. e. sol. hot alcohol.

DI-*p*-TOLYL KETONE $CO(C_6H_4Me)_2$. [92°]. (333°) at 725 mm. Formed by oxidation of di-tolyl-methane (Weiler, *B.* 7, 1183), of *u*-di-tolyl-ethane (O. Fischer, *B.* 7, 1195), and of *u*-di-tolyl-ethylene (Hepp, *B.* 7, 1414) by chromic acid mixture.

Preparation.—50 g. $AlCl_3$, 65 c.c. toluene, 50 c.c. CS_2, and 11 c.c. of a solution of $COCl_2$ in CS_2 saturated at 0° are put into a corked half-litre flask and gently warmed. After 20 minutes HCl is allowed to escape and a second 11 c.c. of CS_2 saturated with phosgene is added. The operation is repeated 2 or 3 times; the yield is 50 p.c. of the calculated (Elbs, *J. pr.* [2] 35, 467; *cf.* Ador a. Crafts, *B.* 10, 2174).

Properties.—Crystals (from alcohol). Converted by HNO_3 at 250° into benzoyl-terephthalic acid. Reduced by HI and P to di-tolyl-methane (Ador a. Rilliet, *B.* 12, 2303).

Oxim $(C_7H_7)_2C:NOH$. [163°]. Prisms (Goldschmidt, *B.* 23, 2746). Decomposes on keeping with sudden evolution of nitrous fumes. Conc. H_2SO_4 at 100° forms the *p*-toluide of *p*-toluic acid.

Di-*p*-tolyl diketone $C_7H_7.CO.CO.C_7H_7$. *p-Tolil.* [105°]. Formed by boiling toluoïn (1 pt.) with HNO_3 (2 pts.) (Stierlin, *B.* 22, 381). Yellow plates (from warm alcohol). Gives a violet colour when boiled with alcoholic potash.

(α)-*Oxim* $C_7H_7.C(NOH).C(NOH).C_7H_7$. [217°]. Plates or needles, sl. sol. alcohol. Yields a diacetyl derivative [134°].

(β)-*Oxim* [225°]. Formed, together with the (α)-oxim, by the action of hydroxylamine hydrochloride on the ketone. Needles, v. sol. alcohol. Yields a di-acetyl derivative [144°].

Di-*p*-tolyl tetraketone $C_7H_7.CO.C(OH)_2.CO.CO.C_7H_7$. [88°]. Formed by the action of nitric acid (S.G. 1·3) on $C_7H_7.CO.CH(OH).CO.CO.C_7H_7$ (Söderbaum, *B.* 25, 3474). Prisms (containing $(C_{18}H_{16}O_5)_2CS_2$) (when crystallised from CS_2).

Di-oxim $C_7H_7.C(NOH).CO.CO.C(NOH).C_7H_7$. [181°]. Plates (containing EtOH) (from alcohol).

Bi-oxim $C_7H_7.CO.C(NOH).C(NOH).CO.C_7H_7$. So called '(β)-nitro-cymene.' [125°]. Mol. w. 324 (by Raoult's method). Formed by the action of nitric acid on cymene and on *p*-tolyl methyl ketone (Holleman, *R. T. C.* 6, 60; *cf.* Landolph, *B.* 6, 937; Fittica, *A.* 172, 311). Needles, v. sol. warm alcohol. Converted by NaOHAq into *p*-toluic acid. Zinc-dust and HOAc reduce it to $C_7H_7.CO.CH_2.CH_2.CO.C_7H_7$ [159°]. Alcoholic NH_3 forms *p*-toluic amide and $C_{16}H_9N_3O_2$ [162°]. Boiling Ac_2O forms $C_{18}H_{18}N_2O_4Ac_2O$ [167°].

Reference.—Oxy-di-tolyl ketone.

TOLYL-MALONAMIC ACID *v.* Malonic acid.

TOLYL-MELAMINE *v.* *Cyanuramide* in the article on Cyanic acids.

***o*-TOLYL-MERCAPTAN** $[1:2]C_6H_4Me.SH$. [15°]. (188°) (H.); (193°) (V.). Formed by reducing (4,1,2)-bromo-tolyl mercaptan (Hübner, *A.* 169, 30; Vallin, *B.* 19, 2953). Prepared by boiling *o*-tolyl ethyl dithiocarbonate with alcoholic potash, the yield being 70 p.c. of the theoretical amount (Leuckart, *J. pr.* [2] 41, 188). Plates.—$Pb(SC_7H_7)_2$. Brick-red pp., turning white in air.

m-**Tolyl mercaptan** $[1:3]C_6H_4Me.SH$. [c. 200°]. Formed by reducing toluene *m*-sulphonic chloride with tin and HCl (Hübner, *A.* 169, 51) and by boiling *m*-tolyl ethyl xanthate with alcoholic potash (L.). Colourless liquid with intense odour of mercaptan. Volatile with steam. In ammoniacal alcoholic solution it is oxidised by air to *m*-tolyl disulphide.

p-**Tolyl mercaptan** $[1:4]C_6H_4Me.SH$. [43°]. (188°) (J.); (191°) (Crafts, *B.* 19, 3130; Otto, *B.* 19, 3129); (194°) (Vallin, *B.* 19, 2953). Formed by reducing toluene *p*-sulphonic chloride with tin and HCl (Märcker, *A.* 136, 79; Javorsky, *Z.* 1865, 222). Formed also by heating *p*-tolyl ethyl xanthate with alcoholic potash (L.). Formed also from di-*p*-tolyl disulphide, alcohol, and H_2S (Otto a. Rössing, *B.* 19, 3130). Unctuous lamina (from ether), volatile with steam. Conc. H_2SO_4 forms a blue solution. Readily oxidised to di-*p*-tolyl disulphide [46°]. Chloro-acetone forms $C_7H_7.S.CH_2.CO.CH_3$ (151° at 15 mm.); S.G. $\frac{15}{15}$ 1·0986 which yields a phenyl-hydrazide

[62°] (Delisle, *A.* 260, 268).—$Hg(SC_7H_7)_2$.—$C_7H_7S.HgCl$. Plates.

Ethyl ether C_7H_7SEt. (221°). S.G. 11 1·0016. Colourless oil (Otto, *B.* 13, 1277).

References.—Amido- and Bromo- tolyl mercaptan.

o-TOLYL-MESITYL-THIO-UREA $C_7H_7.NH.CS.NHC_6H_2Me_3$. [167°]. Formed from *o*-toluidine and mesityl thiocarbimide (Eisenberg, *B.* 15, 1014). Needles, insol. Aq.

DI-TOLYL-METHANE $CH_2(C_7H_7)_2$. [23°]. (286°).

Formation.—1. From formic aldehyde (or methylal), toluene, and H_2SO_4 (Weiler, *B.* 7, 1181).—2. By reducing di-tolyl ketone with HI and P (Ador a. Rilliet, *B.* 12, 2302).—3. A product of the action of $AlCl_3$ and toluene on CH_2Cl_2, on CH_3Cl, or on $CCl_3.NO_2$ (Friedel a. Crafts, *A. Ch.* [6] 11, 266; *Bl.* [2] 43, 50; Elbs a. Wittich, *B.* 18, 347).

Properties.—Prisms, v. sol. ether. Oxidised by chromic acid mixture to di-tolyl ketone, toluyl-benzoic acid, and $CO(C_6H_4.CO_2H)_2$. Yields a di-nitro- derivative [164°].

Tri-tolyl-methane $CH(C_7H_7)_3$. [73°]. (377°). Obtained from tri-amido-tri-tolyl-carbinol (Rosenstiehl a. Gerber, *A. Ch.* [6] 2, 353). Crystalline.

References.—Di-bromo- and Di-chloro-, di-tolyl-methane.

o-TOLYL METHYL-p-AMIDO-PHENOL

Methyl derivative $C_7H_7NMe.C_6H_4OMe$. (336° cor.). From $C_7H_7NH.C_6H_4OH$, KOH, and MeI (Philip, *J. pr.* [2] 34, 59). Oil.

TOLYL-METHYL-AMINE *v.* Methyl-toluidine, Methyl-benzyl-amine, and Amido-xylene.

Di-p-tolyl-methyl-amine $(C_7H_7)_2NMe$. (235°–240° at 20 mm.). Formed from ditolylamine, MeOH, and HCl at 250°-280° (Girard, *Bl.* [2] 24, 120). Does not combine with acids.

DI-TOLYL-DI-METHYL-DI-TRIAZYL

$\begin{matrix}N\;N(C_7H_7)\\CMe.N\end{matrix}\!\!>C.C<\!\!\begin{matrix}N(C_7H_7).N\\N\text{———}CMe\end{matrix}$ (259°–260°). Formed by boiling *p*-tolyl-hydrazine cyanide $(C_7H_7NH.NH_2)_2Cy_2$ with Ac_2O (Bladin, *B.* 22, 3114). Crystals (from alcohol), m. sol. alcohol.

p-TOLYL-METHYL-BENZYL KETONE $C_6H_4Me.COCH_2.C_6H_4Me$. [102°]. Got by reducing *p*-toluoïn with zinc and alcoholic HCl (Stierlin, *B.* 22, 383). Needles, insol. water, v. sol. benzene.

o-TOLYL-METHYLENE-AMINE $C_7H_7N:CH_2$ (?). Formed by adding *o*-toluidine to a solution of formic aldehyde (Wellington a. Tollens, *B.* 18, 3307). Colourless syrup.

p-Tolyl-methylene-amine $C_7H_7N:CH_2$ (?). [c. 122°]. Formed, together with a polymeride sl. sol. benzene and alcohol, by adding *p*-toluidine to a solution of formic aldehyde (W. a. T.). Crystals, v. sol. benzene.

Di-o-tolyl-methylene-diamine $(C_7H_7NH)_2CH_2$. (over 350°). Formed, together with the following solid isomeride, by heating *o*-toluidine with CH_2Cl_2 at 110°–115° (Grünhagen, *A.* 256, 305). Liquid, v. sol. ether and alcohol.—$B'_2H_2PtCl_6$: brown amorphous powder.

Isomeride [c. 135°]. Crystalline powder, sl. sol. cold alcohol.—Salts: $B''2HCl$.—$B''2HBr$.—$B''H_2SO_4$.—$B''2H_3PO_4$.—$B''3H_2C_2O_4$.—$B''2H_2C_2O_4$. Radiating aggregates.

Di-p-tolyl-methylene-diamine $(C_7H_7.NH)_2CH_2$. (above 350°). Formed, together with the solid isomeride, by heating *p*-toluidine with CH_2Cl_2 (G.). Oil, v. sol. ether.—$B''HCl$.—$B''_2H_2PtCl_6$.—$B''HAuCl_4$.

Isomeride $C_{15}H_{18}N_2$. [c. 156°]. (over 350°). Amorphous, sl. sol. ether.—$B''2HCl$ (?).—$B''H_2PtCl_6$.—$B''2HAuCl_4$.—$B''2H_2C_2O_4$. Crystalline crusts.

Di-p-tolyl-di-methylene-diamine

$C_7H_7N\left<\begin{matrix}CH_2\\CH_2\end{matrix}\right>NC_7H_7$. [90°]. A product of the action of CH_2Cl_2 on *p*-toluidine at 100° (Grünhagen, *A.* 256, 296). Granules, sol. hot alcohol. Converted by nitrous acid into a crystalline nitroso- derivative $(C_7H_7N)_2C_2H_2(NOH)$ (?)—$B''2HCl$.—$B''2HAuCl_4$.—$B''2HBr$.—$B''H_2SO_4$.

o-Tolyl-trimethylene-diamine $C_3H_6(NH_2).NHC_7H_7$. (281°). Formed by reducing *o*-tolyl-pyrazole dihydride in alcoholic solution by sodium (Balbiano, *G.* 18, 354). Oil.

p-Tolyl-trimethylene-diamine $C_3H_6(NH_2).NHC_7H_7$. [c. −15°]. (287°). A product of the action of Na on an alcoholic solution of *p*-tolyl-pyrazole (Balbiano). Liquid. Oxalate. [208°]. Spherical groups of minute needles.

p-TOLYL METHYLENE METHYL SULPHONE KETONE $C_7H_7.SO_2.CH_2.CO.CH_3$. [51°]. Formed from chloro-acetone and sodium toluene *p*-sulphinate (Otto, *J. pr.* [2] 36, 401). Silky needles. Yields a bromo- derivative [130°].

m-TOLYL-METHYLENE-PHTHALIDE

$C_6H_4\left<\begin{matrix}C(CHC_7H_7)\\CO\text{———}\end{matrix}\right>O$. [153°]. Formed by heating *m*-tolyl-acetic acid with phthalic anhydride and a little NaOAc (Heilmann, *B.* 23, 3157). Needles (from ligroïn), sl. sol. ether.

p-Tolyl-methylene-phthalide $C_{16}H_{12}O_2$. *p-Xylal-phthalide.* [151°]. Formed in like manner from *p*-tolyl-acetic acid (Ruhemann, *B.* 24, 3965). Yellow needles (from alcohol), sl. sol. ether. Nitrous acid passed into its solution in chloroform forms $C_6H_4\left<\begin{matrix}C(C(NO_2).C_7H_7)\\CO\text{————}\end{matrix}\right>O$ [140°], which may be reduced to the compound $C_6H_4\left<\begin{matrix}CH:C.C_7H_7\\CO.O\end{matrix}\right.$. [116°].

Reference.—Nitro-tolyl-methylene-phthalide.

m-TOLYL-METHYLENE-PHTHALIMIDINE

$C_6H_4\left<\begin{matrix}C(CHC_7H_7)\\CO\text{———}\end{matrix}\right>NH$. [165°]. Formed by heating *m*-tolyl-methylene-phthalide with alcoholic ammonia (Heilmann, *B.* 23, 3161). Yellowish needles.

p-Tolyl-methylene-phthalimidine $C_{16}H_{13}NO$. [204°]. Formed by heating *p*-tolyl-methylene-phthalide with alcoholic NH_3, the compound $NH_2.CO.C_6H_4.CO.CH_2C_7H_7$ being first formed (Ruhemann, *B.* 24, 3968). Converted by passing nitrous acid through its solution in chloroform into $C_6H_4\left<\begin{matrix}C(C(NO_2).C_7H_7)\\CO\text{————}\end{matrix}\right>NH$ [227°].

Isomeride $C_6H_4\left<\begin{matrix}CH:C.C_7H_7\\CO.NH\end{matrix}\right.$. [228°]. Formed by heating $C_6H_4\left<\begin{matrix}CH:C.C_7H_7\\CO.O\end{matrix}\right.$ with alcoholic ammonia (R.).

Reference.—Nitro-tolyl-methylene-phthalimidine.

DI-*p*-TOLYL TRIMETHYLENE DISULPHONE $C_3H_6(SO_2C_7H_7)_2$. [125°]. Formed from trimethylene bromide and sodium toluene *p*-sulphinate (Otto, *B.* 24, 1834). Plates. Converted by alcoholic potash at 120° into the compound $O(CH_2.CH_2.CH_2.SO.C_7H_7)_2$ [80°].

TOLYL-METHYL-IMESATIN *v.* *Toluide* of *Methyl*-ISATIN.

***m*-TOLYL METHYL KETONE** $C_7H_7.CO.CH_3$ *Methyl-acetophenone.* (219°). Formed by distilling calcium *m*-toluate with calcium formate (Buchka a. Irish, *B.* 20, 1766).

Tolyl methyl ketone. (225°). S.G. ^{22} ·9891. V.D. 4·58. Formed, together with the *p*-compound, by the action of AcCl on toluene and $AlCl_3$ (Essner a. Gossin, *Bl.* [2] 42, 95). This is perhaps the *o*-compound.

***p*-Tolyl methyl ketone.** (217°) (M.); (230° cor.) (W.). Formed by the action of $AlCl_3$ on a mixture of toluene and Ac_2O or AcCl (Michaelis, *B.* 15, 185; Claus, *B.* 19, 234). Formed also by heating toluene with HOAc, $ZnCl_2$, and $POCl_3$ (Frey, *J. pr.* [2] 43, 114) and as a by-product in the oxidation of (*a*)-nitro-cymene (Widman, *B.* 19, 587). Oil. Yields a dibromide $C_9H_8Br_2O$ [100°]. $KMnO_4$ forms terephthalic acid. Alkaline K_3FeCy_6 forms *p*-toluic and *p*-tolyl-glyoxylic acids (B. a. K.). HNO_3 forms $C_{18}H_{14}N_2O_4$ [125°], which is reduced by zinc-dust and HOAc to $C_2H_4(CO.C_7H_7)_2$ (Hollemann, *R. T. C.* 10, 211).

Oxim [88°]. Crystals (from ligroïn).

Phenyl-hydrazide [97°]. Prisms.

Reference.—AMIDO-, IODO-, and OXY-, TOLYL METHYL KETONE.

***o*-TOLYL METHYL KETONE TETRAHYDRIDE** $CH_2\left<\begin{matrix}CH_2.CMe\\CH_2.CH_2\end{matrix}\right>C.CO.CH_3$. (206°). Formed from *aω*-di-acetyl-pentane by treatment with conc. H_2SO_4 (Kipping a. Perkin, jun., *C. J.* 57, 18). Oil, smelling like peppermint. Does not combine with $NaHSO_3$. In moist ether it is reduced by Na to the hexahydride.

Oxim $C_9H_{15}NO$. Liquid.

Phenyl hydrazide $C_{15}H_{20}N_2$. Oil.

Tolyl methyl ketone hexahydride *v.* METHYL-HEXAMETHYLENYL METHYL KETONE.

***m*-TOLYL-METHYL-MALONIC ACID** $[1:3]C_6H_4Me.CH_2.CH(CO_2H)_2$. [133°]. Formed by saponification of the ether (Poppe, *B.* 23, 110). Rhombohedra, sl. sol. water.—K_2A'': needles.

Methyl ether Me_2A''. (c. 300°).

Ethyl ether Et_2A''. (320°). Formed from *ω*-bromo-*m*-xylene and sodium malonic ether. Oil. Converted by alcoholic NH_3 at 150° into $C_6H_4Me.CH_2.CH(CO_2Et).CO.NH_2$ [186°], which on warming with water forms the ammonium salt $C_6H_4Me.CH_2.CH(CO_2Et).CO_2NH_4$ [77°]. Et_2A'' is converted by methylamine into the methylamide $C_6H_4Me.CH_2.CH(CO_2Et).CONHMe$ [120°], and by aniline into $C_6H_4Me.CH_2.CH(CO.NHPh)_2$ [188°].

Di-*m*-tolyl-di-methyl-malonic ether $(C_6H_4Me.CH_2)_2C(CO_2Et)_2$. [122°]. A product of the action of *ω*-bromo-*m*-xylene on sodium malonic ether (Poppe, *B.* 23, 109).

***o*-TOLYL-METHYL-OXAZOLINE** $C_{11}H_{13}NO$ *i.e.* $\begin{matrix}CHMe.O\\CH_2—N\end{matrix}\!\!>C.C_7H_7$. (258°). Formed by boiling $C_7H_7.CO.NH.CH_2.CHMeBr$ with alcoholic potash (Salomon, *B.* 26, 1323). Oil.—$B'C_6H_3N_3O_7$. [129°].—$B'_2H_2PtCl_6$.

***p*-Tolyl-methyl-oxazoline** $C_{11}H_{13}NO$. (265°). Formed from the bromopropyl-amide of *p*-toluic acid (Salomon, *B.* 26, 1326). Oil.—Picrate $B'C_6H_3N_3O_7$. [183°].—$B'_2H_2PtCl_6$. [184°].

***p*-TOLYL-DI-METHYL-PHOSPHINE** $C_7H_7PMe_2$. (210°). Formed from $C_7H_7PCl_2$ and $ZnMe_2$ (Czimatis, *B.* 15, 2014). Oil, oxidised by HgO to $C_7H_7PMe_2O$. CS_2 forms $C_7H_7PMe_2CS_2$ [110°] crystallising in red plates.

Methylo-iodide B'MeI. [255°]. Needles. Yields $B'MeI_3$ and $B'_2Me_2PtCl_6$.

Benzylo-chloride. Yields $B'_2(C_7H_7)_2PtCl_6$ [226°], a yellow crystalline pp.

***p*-TOLYL-METHYLPHTHALIMIDE** $[4:2:1]C_6H_3Me:C_2O_2:N.C_6H_4Me$. [180°]. Formed by distilling (4,2,1)-methyl-phthalic acid with *p*-toluidine (Niementowski, *M.* 12, 630). Crystalline mass, v. e. sol. chloroform, insol. water.

***p*-TOLYL-METHYL-PHTHALIMIDINE** $C_6H_4\left<\begin{matrix}CH(CH_2.C_6H_4Me)\\CO\end{matrix}\right>NH$. [149°]. Formed from *p*-tolyl-methylene-phthalimidine, HI and P (Ruhemann, *B.* 24, 39[illegible]). Needles.

DI-*p*-TOLYL-METHYL-PIPERAZINE $C_{19}H_{21}N_2$. [105°]. Formed from di-*p*-tolyl-propylene-diamine, ethylene bromide, and Na_2CO_3. Needles (from alcohol) (Bischoff, *B.* 25, 3278).

***o*-TOLYL-METHYL-PROPYLENE-*ψ*-THIO-UREA** $\begin{matrix}CHMe.S\\CH_2—N\end{matrix}\!\!>C.NMe.C_7H_7$. (c. 295°). Formed from *o*-tolyl-propylene-*ψ*-thio-urea and MeI (Prager, *B.* 22, 2999). Yields (*β*)-methyl-taurine on oxidation.—$B'C_6H_3N_3O_7$. [138°].—B'HI. [166°].—$B'_2H_2PtCl_6$. Decomposes over 200°.

***p*-TOLYL-DI-METHYL-PYRROLE** $(C_7H_7)N\left<\begin{matrix}CMe:CH\\CMe:CH\end{matrix}\right.$. [46°]. (255°). Got by heating the di-carboxylic acid (Knorr, *B.* 18, 308). Crystals, volatile with steam.

Reference.—AMIDO-TOLYL-DI-METHYL-PYRROLE.

***p*-TOLYL-DI-METHYL-PYRROLE DICARBOXYLIC ACID** $(C_7H_7)N\left<\begin{matrix}CMe:C.CO_2H\\CMe:C.CO_2H\end{matrix}\right.$. Got by saponifying its ether, which is formed by mixing acetic acid solutions of di-acetyl-succinic ether and *p*-toluidine (Knorr, *B.* 18, 304). Needles, decomposes at about 250°, with evolution of CO_2.—K_2A''.—$AgHA''$.

Ethyl ether Et_2A''. [67°]. Tables.

Reference.—AMIDO-TOLYL-DI-METHYL-PYRROLE DICARBOXYLIC ACID.

***p*-TOLYL-DI-METHYL-SULPHAMIDE** $SO_2(NMe_2).NHC_7H_7$. [91°]. Formed from $NMe_2.SO_2Cl$ and *p*-toluidine (Behrend, *A.* 222, 129). Crystals, v. sol. alcohol and ether.

***p*-TOLYL METHYL SULPHONE** $C_7H_7.SO_2.CH_3$. [87°]. Formed by the action of conc. KOHAq on *p*-tolyl-sulphono-acetic acid (Otto, *B.* 18, 161). Got also from $C_7H_7.SO_2Na$ and MeI (Otto). Needles (from very dilute alcohol), v. sol. hot water.

***o*-TOLYL-METHYL-THIAZOLINE** $\begin{matrix}CHMe.S\\CH_2—N\end{matrix}\!\!>C.C_7H_7$. (284°-295°). Formed by heating *o*-toluic bromo-propylamide with P_2S_5 at 150° (Salomon, *B.* 26, 1328). Oil.—$B'C_6H_3N_3O_7$. [136°].

***p*-Tolyl-methyl-thiazoline** $C_{11}H_{13}NS$. (295°). Oil.—$B'C_6H_3N_3O_7$. [141°].—$B'_2H_2PtCl_6$.

o-TOLYL-METHYL-THIOHYDANTOÏN

$\mathrm{HMe}<\begin{matrix}\mathrm{CO.N(C_7H_7)}\\ \mathrm{NH.CS}\end{matrix}$. [198°]. Formed from *o*-tolyl-thiocarbimide and alanine (Marckwald, *B.* 24, 3281). Crystals.

p - Tolyl-methyl - thiohydantoïn. [197°]. Formed in like manner from *p*-tolyl-thiocarbimide and alanine (Aschan, *B.* 17, 427). Minute prisms. On heating with alcoholic potash it is converted by hydrolysis into a salt of the oily $NHC_7H_7.CS.NH.CHMe.CO_2H$, which slowly changes, in the free state, back into the hydantoïn.

o-Tolyl-di-methyl-thiohydantoïn

$\mathrm{CMe_2}<\begin{matrix}\mathrm{CO.N(C_7H_7)}\\ \mathrm{NH.CS}\end{matrix}$. [175°]. Formed from *o*-tolyl-thiocarbimide and *α*-amido-isobutyric acid (Marckwald, *B.* 24, 3284). Needles, v. sol. hot alcohol.

p-Tolyl-di-methyl-thiohydantoïn. [85°]. Formed in like manner from *p*-tolyl-thiocarbimide. Crystals, v. sol. most solvents.

o-TOLYL-METHYL-THIO-UREA $NHMe.CS.NHC_7H_7$. [153°]. Formed from methyl-thiocarbimide and *o*-toluidine in alcohol (Dixon, *C. J.* 55, 622). Pearly crystals, m. sol. hot water, sol. alcohol.

p-Tolyl-methyl-thio-urea. [126°]. Formed in like manner from *p*-toluidine. Vitreous prisms, v. sol. hot water.

Reference.—Tolyl-thio-urea.

o-TOLYL-(α)-NAPHTHYLAMINE $C_{17}H_{15}N$ *i.e.* $C_{10}H_7.NH.C_6H_4Me$. [95°]. Formed by heating (*α*)-naphthol (1 mol.) with *o*-toluidine (2 mols.) and $CaCl_2$ (1 mol.) in sealed tubes at 290°, the yield being 37 p.c. of the theoretical amount (Friedländer, *B.* 16, 2084). Flat needles, v. sol. alcohol and ether.

o-Tolyl-(β)-naphthylamine $C_{10}H_7NH.C_6H_4Me$. [96°]. Formed by heating a mixture of (*β*)-naphthol with *o*-toluidine and $CaCl_2$ at 280°. Silvery plates (from ligroïn), v. sol. alcohol.—$B'2C_6H_3N_3O_7$. [110°]. Reddish-brown needles.

Benzoyl derivative [118°]. Plates.

p-Tolyl-(α)-naphthylamine $C_{17}H_{15}N$. [79°]. (360° at 528 mm.). Formed by heating (*α*)-naphthol with *p*-toluidine and $CaCl_2$ at 280°, the yield being 50 p.c. Short prisms (from alcohol). Its solutions exhibit blue fluorescence.

p-Tolyl-(β)-naphthylamine. [104°]. Formed by heating *p*-toluidine hydrochloride with (*β*)-naphthol for 8 hours at 200° (Witt, *B.* 20, 578; *cf.* Friedländer, *B.* 16, 2078). Plates (from alcohol). Its solutions have violet-blue fluorescence. Dissolved in isoamyl alcohol it is reduced by Na to a hydride [44°] (Bamberger a. Müller, *B.* 22, 1309). With nitroso-dimethyl-aniline hydrochloride and HOAc it yields a saffranine $C_{10}H_6N_2Cl(C_7H_7):C_6H_3NMe_2$ (Witt, *B.* 21, 724). *p*-Tolyl-naphthyl-amine (10 g.), heated with nitroso-dimethylaniline hydrochloride (4 g.), $ZnCl_2$ (10 g.), and HOAc (100 c.c.), forms $C_{20}H_{12}(NH.C_6H_4Me)_2$ [225°], which yields an acetyl derivative [225°].

Acetyl derivative [85°]. Needles.

Benzoyl derivative [139°]. Needles.

Reference. — Tetra-bromo-tolyl-naphthylamine.

DI-p-TOLYL-NAPHTHYLENE-DIAMINE $C_{10}H_6(NHC_7H_7)_2$. [237°]. Formed by heating di-oxy-naphthalene with *p*-toluidine and *p*-toluidine hydrochloride (Annaheim, *B.* 20, 137 Needles (from xylene). Gives a red colour o heating with solid $ZnCl_2$.

o-TOLYL-(α)-NAPHTHYL-THIO-UREA $CS(NHC_{10}H_7)(NHC_7H_7)$. [168°]. Formed b the action of *o*-tolyl thiocarbimide on (*α*)-naph thylamine or of (*α*)-naphthyl thiocarbimide o *o*-toluidine (Mainzer, *B.* 15, 1416). Sho needles, sol. alcohol. Split up by conc. HClA at 150° into *o*-toluidine, (*α*)-naphthylamin *o*-tolyl-thiocarbimide, and (*α*)-naphthyl thi carbimide.

o - Tolyl - (β) - naphthyl - thio - urea [194° Formed from *o*-tolyl thiocarbimide and (*β*)-nap thylamine (M.).

p - Tolyl - (α) - naphthyl - thio - urea [168° Formed from *p*-tolyl thiocarbimide and (*α*)-naph thylamine (M.). Slender white needles.

p - Tolyl - (β) - naphthyl - thio - urea [164° Formed from *p*-tolyl thiocarbimide and (*β*) naphthylamine (M.). Decomposed by HClAq a 150° into *p*-toluidine, (*β*)-naphthylamine, *p*-toly thiocarbimide, and (*β*)-naphthyl thiocarbimide.

p-TOLYL p-NITRO-BENZYL OXIDE $C_6H_4Me.O.CH_2.C_6H_4.NO_2$. [91°]. Formed fro *p*-nitro-benzyl chloride and alcoholic C_7H_7ON (Frische, *A.* 224, 144). Yellowish plates, so ether.

TOLYL NITROSO-METHYL KETONE v *Oxim* of Tolyl-glyoxal.

TOLYL-OXAMIC ACID *v.* vol. iii. p. 654.

TOLYL-OXAMIDE *v.* Oxalic acid.

o-TOLYL-OXAZOLINE

$\begin{matrix}\mathrm{CH_2.O}\\ \mathrm{CH_2.N}\end{matrix}\!\!>\!\mathrm{C.C_7H_7}$. (255°). Formed by dissolving *o*-toluic bromo ethyl-amide in hot water and adding alkal (Salomon, *B.* 26, 1322). Oil. Evaporating wit aqueous HCl (1 mol.) forms the compoun $C_7H_7.CO.O.CH_2.CH_2.NH_2$, while excess of HC gives $C_7H_7.CO.NH.CH_2.CH_2Cl$. — $B'C_6H_3N_3O$ [145°].—$B'_2H_2PtCl_6$. [189°].

p-Tolyl-oxazoline $C_{10}H_{11}NO$. [66°]. (265°) Formed by decomposing $C_7H_7.CO.NH.CH_2.CH_2B$ with alkali. Needles.—$B'C_6H_3N_3O_7$. [188°].—$B'_2H_2PtCl_6$. [186°].

DI-o-TOLYL OXIDE $(C_6H_4Me)_2O$. *Cresy ether.* (272°–278°). S.G. ${}^{24.8}$ 1·047. A produc of the distillation of $Al(OC_6H_4Me)_3$ (Gladstone a Tribe, *C. J.* 49, 27). Oil, smelling like geraniu leaves.

Di-m-tolyl oxide $(C_7H_7)_2O$. (284°–288°) μ_a 1·5576 at 16°. V.D. 193·9. A product o distillation of aluminium thymol $Al(OC_{10}H_{13})$ (Gladstone a. Tribe, *C. J.* 41, 13). Oil.

Di-p-tolyl oxide $(C_7H_7)_2O$. [50°]. (270°–300°) Formed by distilling aluminium *p*-cresol (C. a T.). Prisms (from alcohol).

Isomeride [165°]. Formed by heatin *p*-cresol with $ZnCl_2$ (Busch, *B.* 17, 2638). Crystals, volatile with steam.

DI-TOLYL-OXINDOLE

$\mathrm{C_6H_4}<\begin{matrix}\mathrm{C(C_7H_7)_2}\\ \mathrm{NH}\end{matrix}>\mathrm{CO}$ *Toluisatin.* [200°]. Formed by adding toluen to a solution of isatin in H_2SO_4 (Baeyer a Lazarus, *B.* 18, 2638). Needles, v. sol. alcoho and ether, sol. aqueous alkalis. Yields an acety derivative $C_{22}H_{18}O(NAc)$ [143°] and an ethy derivative $C_{22}H_{18}O(NEt)$ [108°], both being crystalline.

TOLYL-OXY-ACETIC ACID *v. Tolyl derivative* of GLYCOLLIC ACID and OXY-TOLYL-ACETIC ACID.

***p*-TOLYL OXY-ETHYL SULPHONE** $C_7H_7.SO_2.CH_2.CH_2OH$. [55°]. Got from sodium toluene *p*-sulphinate and glycol chlorhydrin (Otto, *J. pr.* [2] 30, 355). Needles (from alcohol) with bitter taste. Heating with KOHAq gives $C_{18}H_{22}S_2O_4$ [84°].

Benzoyl derivative $C_7H_7.SO_2.C_2H_4.OBz$. [176°]. Needles, sl. sol. hot alcohol.

DI-*o*-TOLYL-PARABANIC ACID $C_{17}H_{14}N_2O_3$ *i.e.*  $CO<\begin{matrix}N(C_7H_7).CO\\N(C_7H_7).CO\end{matrix}$ [203°]. Formed by boiling an alcoholic solution of oxalyl-di-tolyl-guanidine with conc. HClAq (Berger, *B.* 12, 1856). Small needles.

Di-*p*-tolyl-parabanic acid [144°]. Formed by boiling di- (or tri-) *p*-tolyl-guanidine dicyanide with alcohol and HCl (Landgrebe, *B.* 11, 978). Plates. Oxidised by potassium permanganate to  $CO<\begin{matrix}N(C_6H_4.CO_2H).CO\\N(C_6H_4.CO_2H).CO\end{matrix}$ [159° ?].

***p*-TOLYL PENTADECYL KETONE** $C_{15}H_{31}.CO.C_6H_4Me$. [60°]. (262° at 15 mm.). Formed from palmityl chloride, toluene, and $AlCl_3$ (Krafft, *B.* 21, 2266). Needles (from alcohol). Yields *p*-toluic acid on oxidation.

***o*-TOLYL-PENTHIAZOLINE** $C_{11}H_{13}NS$ *i.e.*  $\begin{matrix}C_7H_7C.S-CH_2\\N.CH_2.CH_2\end{matrix}$. Got by heating trimethylene chlorobromide with thio-*o*-toluic amide (Pinkus, *B.* 26, 1081). Oil, volatile with steam. Its hydrochloride gives a white compound with $HgCl_2$.

***p*-Tolyl-penthiazoline** [53°].

***p*-TOLYL-PHENTLIAZINE.** *Dihydride* $C_6H_4<\begin{matrix}N=N\\CH_2.N.C_7H_7\end{matrix}$ [151°]. Formed by the action of HNO_2 on *o*-amido-benzyl-*p*-toluidine hydrochloride (Busch, *B.* 25, 450). Yellow plates (from alcohol).—B'HCl.—$B'_2H_2PtCl_6$. [190°].—$B'C_6H_3N_3O_7$. [132°]. Dark-yellow needles.

***p*-TOLYL-PHENYL-ACETAMIDINE** $C_{15}H_{16}N_2$ *i.e.* $C_6H_5.CH_2.C(N.C_6H_4Me).NH_2$. [119°]. Formed by heating phenyl-acetonitrile with *p*-toluidine hydrochloride (Bernthsen, *A.* 184, 342). Crystals (from alcohol).—$B'_2H_2PtCl_6$: yellow prisms.

DI-*p*-TOLYL-DIPHENYLACETYLENE-DIAMINE $C_{28}H_{24}N_2$ *i.e.* $C_7H_7N:CPh.CPh:NC_7H_7$. [161°]. Formed, together with $Bz.CPh:NC_7H_7$ [116°], by heating benzil (1 mol.) with *p*-toluidine (2 mols.) at 130° (Bandrowski, *M.* 9, 690). Triclinic plates.

DI-TOLYL-PHENYLENE-DIAMINE *v.* PHENYLENE-DI-TOLYL-DIAMINE.

TOLYL PHOSPHATES.

Tri-*o*-tolyl-phosphate $(C_7H_7O)_3PO$. Formed by heating *o*-cresol with $POCl_3$, the yield being 95 p.c. (Heim, *B.* 16, 1767; Rapp, *A.* 224, 173). Oil, sol. alcohol and ether.

***p*-Tolyl phosphate** $PO(OC_7H_7)(OH)_2$. [116°]. Formed by the action of water on $PO(OC_7H_7)Cl_2$, which is a product of the action of $POCl_3$ on *p*-cresol (Rapp, *A.* 224, 168). Plates, sol. alcohol, ether, and water.

Tri-*p*-tolyl phosphate $PO(OC_7H_7)_3$. [78°]. Formed by heating *p*-cresol with $POCl_3$, the yield being 95 p.c. Colourless tables, insol. Aq.

***p*-TOLYL-PHOSPHINE** $C_7H_7NH_2$. [4°]. (178°). Formed by the action of $AlCl_3$ on a mixture of toluene and PCl_3, the resulting $C_7H_7PCl_2$ [20°] (245°), being converted by water into $C_7H_7P(OH)_2$, which splits up on heating into tolyl-phosphine and toluene phosphonic acid $C_7H_7PO_3H_2$ (Michaelis, *B.* 12, 1009; 13, 653; *A.* 212, 230). Oil with strong odour. Rapidly oxidised by air to $C_7H_7P(OH)_2$. HI forms $C_7H_7PH_3I$, crystallising in colourless needles.

***p*-TOLYL-PHTHALIDE** $C_{15}H_{12}O_2$ *i.e.*  $C_6H_4<\begin{matrix}CO\text{———}\\CH(C_7H_7)\end{matrix}>O$. [129°]. Formed by reducing $C_7H_7.CO.C_6H_4.CO_2H$ in alcoholic solution with Zn and HCl (Gresly, *A.* 234, 235). Needles, sol. hot alcohol, insol. NH_3Aq.

Di-*p*-tolyl-phthalide  $C_6H_4<\begin{matrix}CO\text{———}\\C(C_7H_7)_2\end{matrix}>O$. [116°]. Formed by heating phthalyl chloride (100 g.) with toluene (450 g.) and $AlCl_3$ (Berchem, *Bl.* [2] 42, 168; *cf.* Friedel a. Crafts, *Bl.* [2] 35, 505). Prisms, sol. alcohol and ether.

TOLYL-PHTHALIMIDE *v. Tolylimide* of PHTHALIC ACID.

***m*-TOLYL-PROPIOLIC ACID** $C_7H_7.C:C.CO_2H$. [109·5°]. Formed by boiling di-bromo-tolyl-propionic acid $C_7H_7.CHBr.CHBr.CO_2H$ with alcoholic potash (Müller, *B.* 20, 1215). $AgNO_3$ gives an explosive white pp.

o-TOLYL-PROPIONIC ACID $C_7H_7.C_2H_4O_2$. Monoclinic prisms (Young, *B.* 25, 3102).

***m*-Tolyl-propionic acid** $C_7H_7.CH_2.CH_2.CO_2H$. [43°]. Formed by reducing *m*-tolyl-acrylic acid with sodium-amalgam (Müller, *B.* 20, 1214; von Miller, *B.* 23, 1899). Needles (from ligroïn), sol. water, alcohol, and ether. Volatile with steam.

***m*-Tolyl-propionic acid** [125°]. Formed by oxidation of *m*-isobutyl-toluene by HNO_3 (Effront, *B.* 17, 2330). Needles, sl. sol. hot water.—AgA': crystals, sol. hot water.

***p*-Tolyl-propionic acid.** [116°] (Von Miller, *B.* 23, 1898); [120°] (Kröber, *B.* 23, 1033). Formed by reducing *p*-tolyl-acrylic acid. Condensed by hot H_2SO_4 to oxy-methyl-indonaphthene.

Di-*a*-tolyl-propionic acid $CH_3.C(C_7H_7)_2.CO_2H$. [152°]. Prepared by adding toluene to a solution of pyruvic acid in H_2SO_4 at −10° (Böttinger, *B.* 14, 1596; 15, 1474). Monoclinic crystals, sol. hot alcohol. Give *a*-di-tolyl-ethane on distillation with lime. Oxidised by $KMnO_4$ to di-phenyl-ethane tri-carboxylic acid.—AgA'.

Ethyl ether EtA'. [145°]. Prisms.

References. — BROMO-, NITRO-, and OXY-, TOLYL-PROPIONIC ACIDS.

***p*-TOLYL-PROPIONIC ALDEHYDE** $C_7H_7.CH_2.CH_2.CHO$. (223°). S.G. ^{13} ·9941. Formed by the action of water on the compound of CrO_2Cl_2 with the cymene got from camphor and P_2O_5 (Richter a. Schüchner, *B.* 17, 1931). Got also by distilling calcium *p*-tolyl-propionate with calcium formate (Miller, *B.* 23, 1082). Oil, smelling like peppermint. Volatile with steam. Yields *p*-toluic and terephthalic acids on oxidation.

DI-*o*-TOLYL-PROPYLENE-DIAMINE $CHMe(NHC_7H_7).CH_2.NHC_7H_7$. (280° at 120 mm.). Got by heating *o*-toluidine with propylene bromide (Bischoff, *B.* 25, 3276).

Acetyl derivative $C_{21}H_{28}N_2O_2$. [120°].

Di-*p*-tolyl-propylene-diamine $C_3H_6(NHC_7H_7)_2$. (277° at 48 mm.) (Bischoff, *B.* 25, 3277). Got from *p*-toluidine and $C_3H_6Br_2$. Oil.

Acetyl derivative $C_{21}H_{28}N_2O_2$. [114°].

Benzoyl derivative $C_{31}H_{30}N_2O_2$. [152°].

o-TOLYL-PROPYLENE-ψ-THIO-UREA

$C_7H_7NH.C<\genfrac{}{}{0pt}{}{S.CHMe}{N.CH_2}$. [126°]. Formed from s-o-tolyl-allyl-thio-urea and HCl (Prager, *B.* 22, 2999). Tables, sl. sol. hot water.—$B'_2H_2PtCl_6$. [178°]. Prisms.—$B'C_6H_3N_3O_7$. [176°]. Cubes.

DI-o-TOLYL-PROPYLENE UREA

$C_3H_6<\genfrac{}{}{0pt}{}{NC_7H_7}{NC_7H_7}>CO$. [93°]. Formed from di-o-tolyl-propylene-diamine and $COCl_2$ (Bischoff, *B.* 25, 3276). Prisms (from dilute alcohol).

Di-p-tolyl-propylene-urea. [130°].

d-TOLYL ISOPROPYL KETONE

$C_6H_4Me.CO.Pr$. (236°). Formed from toluene, isobutyryl chloride and $AlCl_3$ (Claus, *J. pr.* [2] 46, 480). Oil, with bitter taste and aromatic odour. Yields p-toluic and terephthalic acids on oxidation. Yields an oxim [92°]. May be reduced to p-tolyl-isopropyl-carbinol; an oil boiling above 300°.

DI-o-TOLYL-PYRAZINE HEXAHYDRIDE

$C_6H_4Me.N<\genfrac{}{}{0pt}{}{CH_2.CH_2}{CH_2.CH_2}>N.C_6H_4Me$. *Di-o-tolyl-piperazine.* [171°]. Formed from ethylene bromide, o-toluidine, and Na_2CO_3 at 160° (Bischoff, *B.* 22, 1781; 23, 1982; *cf.* Mauthner a. Suida, *M.* 7, 233). Crystals (from ether).

Isomeride. [154°]. Formed by heating di-o-tolyl-ethylene-diamine with chloro-acetic acid and NaOAc (Bischoff, *B.* 23, 2031). Thin needles (from alcohol).

Di-p-tolyl-pyrazine hexahydride

$C_7H_7.N<\genfrac{}{}{0pt}{}{CH_2.CH_2}{CH_2.CH_2}>N.C_7H_7$. [188°]. Formed from p-toluidine and $C_2H_4Br_2$ in presence of NaOAc or Na_2CO_3. Prisms, sl. sol. alcohol. With $NaNO_2$ and HOAc it yields a di-nitroso-derivative [167°].

o-TOLYL-PYRAZOLE

$CH<\genfrac{}{}{0pt}{}{CH.N.C_7H_4Me}{CH:N}$ (246·5° cor.). S.G. $\frac{0}{0}$ 1·0868; $\frac{13}{0}$ 1·0753. Formed by boiling epichlorhydrin (1 mol.) with o-tolyl-hydrazine (2 mols.) and benzene, boiling off the benzene, and heating the residue at 150° (Balbiano, *G.* 18, 368). Not reduced by boiling with alcohol and Na.—$B'_2H_2PtCl_6$. [201°].—B'EtI. [100°]. Needles, v. e. sol. water.

Dihydride $C_3H_5N_2.C_7H_7$. (271°). S.G. $\frac{0}{0}$ 1·084. Formed from acroleïn tolyl-hydrazide and dilute (2 p.c.) H_2SO_4. Oil. Sol. fuming HClAq, but reppd. by water. $K_2Cr_2O_7$ and H_2SO_4 give an indigo-blue colour.

p-Tolyl-pyrazole. [33°]. (259° cor.). Formed, in like manner, from epichlorhydrin and p-tolyl-hydrazine. Yellowish plates, sl. sol. hot water.—$B'_2H_2PtCl_6$2aq: needles. [184°].—B'EtI. [105°]. Prisms, v. sol. water.

Dihydride. [60·5°]. (282° i.V.). Formed from acroleïn p-tolyl-hydrazide and dilute H_2SO_4. Got also by reducing p-tolyl-pyrazole in alcoholic solution by Na. Iridescent plates, sl. sol. hot water. Its acidified solution is coloured violet-red by $K_2Cr_2O_7$.

p-TOLYL-PYRIDINE HEXAHYDRIDE

$C_6H_4Me.N.C_5H_{10}$. (262°). Formed by heating piperidine with p-bromo-toluene at 270° (Lellmann a. Just, *B.* 24, 2099). V. sol. alcohol and benzene.

p-TOLYL-PYRROLE $C_{11}H_{11}N$ *i.e.*

$\genfrac{}{}{0pt}{}{CH:CH}{CH:CH}>NC_6H_4Me$. Got by dry distillation of p-toluidine mucate (Lichtenstein, *B.* 14, 933). Converted by AcCl into crystalline $C_7H_7NC_4Ac_4$.—B'_2HgCl_2.

Di-p-tolyl-pyrrole

$\genfrac{}{}{0pt}{}{CH:C(C_7H_7)}{CH:C(C_7H_7)}>NH$. [197°]. Formed by treating di-p-tolyl-furfurane or $(C_7H_7.CO)_2C_2H_4$ with NH_4OAc (Hollemann, *R. T. C.* 6, 73). Small plates with bluish lustre. Does not form a K derivative. Boiling HClAq gives a red resin. With isatin, after several days, it gives an intense red colour.

o-TOLYL-QUINAZOLINE DIHYDRIDE

$C_{15}H_{14}N_2$ *i.e.*

$C_6H_4<\genfrac{}{}{0pt}{}{N=CH}{CH_2.N.C_6H_4Me}$. Formed by reducing the formyl derivative of o-nitro-benzyl-o-toluidine with tin and HClAq (Paal a. Busch, *B.* 22, 2701). Oil.—$B'HSnCl_3$.—B'HCl: amorphous.—$B'_2H_2PtCl_6$. [210°]. Needles (from alcohol containing HCl).

p-Tolyl-quinazoline dihydride. [120°]. Formed in like manner. Plates, v. sol. alcohol.—$B'HSnCl_3$. [165°].—B'HCl 2aq. [85°].—B'HCl. [251°].—$B'_2H_2PtCl_6$. [216°]. Yellow needles.

Methylo-iodide B'MeI. [186°]. Needles.

p-Tolyl-quinazoline tetrahydride

$C_6H_4<\genfrac{}{}{0pt}{}{NH.CH_2}{CH_2.NC_6H_4Me}$. [127°]. Formed by reducing the dihydride in alcoholic solution by sodium. Needles, m. sol. alcohol. Yields a nitrosamine [100°]. Yields a crystalline hydrochloride.

Reference.—Oxy-tolyl-quinazoline.

(*Py.* 3)-**o-TOLYL-QUINOLINE** $C_{16}H_{13}N$ *i.e.*

$C_6H_4<\genfrac{}{}{0pt}{}{CH:CH}{N=C.C_6H_4Me}$. [77°]. Formed by distilling oxy-tolyl-quinoline (pseudoflavenol) with zinc-dust (Weidel a. Bamberger, *M.* 9, 108). Silky needles (from benzene).—$B'_2H_2PtCl_6$ (dried at 105°). Orange tables.

m-Tolyl-isoquinoline

$C_6H_4<\genfrac{}{}{0pt}{}{CH:C.C_7H_7}{CH:N}$. [52°]. Formed by heating (1)-chloro-(3)-m-tolyl-isoquinoline with HI and P for three hours at 170° (Heilmann, *B.* 23, 3168). Needles (from MeOH).

p-Tolyl-isoquinoline

$C_6H_4<\genfrac{}{}{0pt}{}{CH:C.C_7H_7}{CH:N}$. [78°]. Formed in like manner (Ruhemann, *B.* 24, 3975). Needles.—B'HI.—$B'H_2CrO_4$.—$B'_2H_2PtCl_6$.—$B'C_6H_3N_3O_7$. Yellow needles.

Reference.—Oxy-tolyl-quinoline.

TETRA-m-TOLYL-SILICANE $Si(C_7H_7)_4$. [151°]. (above 550°). S.G. ^{20} 1·1188. Formed from m-bromo-toluene, $SiCl_4$, and sodium (Polis, *B.* 19, 1021). Prisms (from ether), v. sol. benzene.

Tetra-p-tolyl-silicane $Si(C_7H_7)_4$. [228°]. (above 450°). S.G. ^{20} 1·0793. Formed from $SiCl_4$, p-bromo-toluene, ether, Na, and a little EtOAc (Polis, *B.* 18, 1542; 19, 1019). Monoclinic crystals (from chloroform). Decomposed by conc. HNO_3, forming silica and di-p-nitro-toluene [72°].

TETRA-o-TOLYL SILICATE $Si(OC_7H_7)_4$. (c. 437°). Formed by heating o-cresol with $SiCl_4$, the yield being 90 p.c. of the theoretical quantity (Hertkorn, *B.* 18, 1686). Oil, v. sol.

alcohol. Decomposed by hot water into silica and *o*-cresol.

Tetra-*m*-tolyl silicate $Si(OC_7H_7)_4$. (445°) at 720 mm. Syrup (H.).

Tetra-*p*-tolyl silicate $Si(OC_7H_7)_4$. [70°]. (444°). Tables or prisms, v. sol. benzene (H.).

***p*-TOLYL SILICO-CHLORIDE** $C_7H_7SiCl_3$. (219°). Formed from $Hg(C_7H_7)_2$ and $SiCl_4$ at 310° (Ladenburg, *A.* 173, 165). Liquid, converted by dilute aqueous ammonia into $C_7H_7.SiO.OH$ [c. 150°], which is converted at 200° into solid $(C_7H_7.SiO)_2O$.

TOLYL SULPHATES.

***o*-Tolyl sulphuric acid** [1:2] $C_6H_4Me.O.SO_2.OH$. Occurs in small quantity in the urine of horses (Preusse, *H.* 2, 355). Prepared from $C_6H_4Me.OK$ and $K_2S_2O_7$ (Baumann, *B.* 11, 1911). The K salt crystallises in plates, m. sol. water.

***m*-Tolyl sulphuric acid** $C_6H_4Me.O.SO_2.OH$. Occurs in very small quantity in horses' urine (P.).

***p*-Tolyl sulphuric acid** $C_6H_4Me.O.SO_2.OH$. Occurs in the urine of horses and cows (Baumann, *B.* 9, 1389, 1716; Städeler, *A.* 77, 18). Formed by boiling potassium *p*-cresol with $K_2S_2O_7$. The K salt is sl. sol. cold alcohol.

DI-*o*-TOLYL-SULPHAZIDE $C_{14}H_{16}N_2SO_2$ *i.e.* [2:1] $C_6H_4Me.NH.NH.SO_2.C_6H_4Me$ [1:2]. *Tolyl-toluene-sulphazide.* [142°]. Obtained by the action of SO_2 upon *o*-diazo-toluene in alcoholic solution. White glistening needles (Limpricht, *B.* 20, 1241). When boiled with baryta-water it decomposes into *o*-toluene-sulphinic acid, toluene, and nitrogen.

Di-*p*-tolyl-sulphazide $C_{14}H_{16}N_2SO_2$ *i.e.* [4:1] $C_6H_4Me.NH.NH.SO_2.C_6H_4Me$ [1:4]. *Tolyl-toluene-sulphazide.* [140°]. Formed in like manner from *p*-diazo-toluene (L.). Small needles. By boiling with baryta-water it is decomposed into *p*-toluene-sulphinic acid, toluene, and nitrogen.

Reference.—Nitro-di-tolyl-sulphazide.

DI-*p*-TOLYL SULPHIDE $S(C_6H_4Me)_2$. [57°]. (above 300°). Formed by distillation of lead *p*-tolyl-mercaptide (Otto, *B.* 12, 1175). Small needles, insol. water, sol. alcohol. Yields di-*p*-tolyl sulphone on oxidation by $KMnO_4$.

Di-*m*-tolyl disulphide $C_{14}H_{14}S_2$ *i.e.* $(C_6H_4Me)_2S_2$. Formed from *m*-tolyl mercaptan by treatment with dilute HNO_3 (Hübner a. Post, *A.* 169, 51). Liquid at −22°. Decomposed on boiling or by atmospheric oxidation of its ammoniacal alcoholic solution (Leuckart, *J. pr.* [2] 41, 189).

Di-*p*-tolyl disulphide $(C_6H_4Me)_2S_2$. [43°]. Formed from *p*-tolyl mercaptan by atmospheric oxidation (Märcker, *A.* 136, 88) or by the action of $ClSO_3H$ (Beckurts a. Otto, *B.* 11, 2066), or by treatment with ICy (Thurnauer, *B.* 23, 769). Formed also by the action of H_2S on a warm dilute solution of toluene *p*-sulphinic acid in alcohol (Otto, *J. pr.* [2] 37, 211). Crystals, v. e. sol. ether. Begins to boil at 307° i.V. but decomposes on distillation. Alcoholic K_2S forms *p*-tolyl mercaptan (Otto a. Rössing, *B.* 19, 3129).

Di-*p*-tolyl tetrasulphide $(C_6H_4Me)_2SO_4$. [75°]. Formed by the action of H_2S on a conc. solution of toluene *p*-sulphinic acid (Otto, *J. pr.* [2] 37, 211). Small plates, insol. water, v. sol. ether.

References.—Di-amido-, Di-bromo-, and Oxy-di-tolyl-sulphide.

***o*-TOLYL SULPHOCYANIDE** $C_6H_4Me.S.CN$. (c. 245°). Formed by adding cuprous sulphocyanide in KSCy to a solution of *o*-diazo-toluene (Thurnauer, *B.* 23, 770). Yellowish-red oil with unpleasant odour.

***p*-Tolyl sulphocyanide.** (c. 248°). Formed in like manner, and also by passing CyCl through alcohol containing lead *p*-tolyl mercaptide. Liquid, solidifying below 0°.

DI-*p*-TOLYL SULPHONE $(C_6H_4Me)_2SO_2$. [158°]. (405°) at 714 mm. Prepared by the action of $AlCl_3$ on a mixture of toluene and toluene *p*-sulphonic chloride (Beckurts a. Otto, *B.* 11, 2068; 12, 1177; *cf.* Michael, *B.* 10, 584). Formed by the action of fuming H_2SO_4 or SO_3 on toluene (Deville, *A.* 44, 306; Otto a. Grüber, *A.* 154, 193) and by the action of $KMnO_4$ and HOAc on di-*p*-tolyl sulphide. Prisms (from benzene), sl. sol. cold alcohol and ether. Potash-fusion yields *p*-cresol and diphenyl (Otto, *B.* 19, 2426).

DITOLYL DISULPHONIC ACID [1:4:5] $C_6H_3Me(SO_3H).C_6H_3Me(SO_4H)$ [5:1:4]. Formed from di-amido-ditolyl disulphonic acid by diazotisation followed by boiling with alcohol (Halle, *A.* 270, 363). Crystals, v. e. sol. water, m. sol. alcohol, insol. ether.—K_2A''. Hexagonal plates.—KHA'': prisms.—BaA'' 5aq.

Chloride $C_{14}H_{12}S_2O_4Cl_2$. [229°].

Amide $C_{14}H_{12}S_2O_4(NH_2)_2$. Needles.

***p*-TOLYL-SULPHONO-ACETIC ACID.** $C_6H_4Me.SO_2.CH_2.CO_2H$. [118°]. Formed from sodium benzene sulphinate and chloro-acetic acid (Gabriel, *B.* 14, 834). Crystals (from benzene), sl. sol. hot water. Cl passed into its aqueous solution forms $C_7H_7SO_2.CHCl_2$ [114°]. Br forms $C_7H_7.SO_2.CHBr_2$ and $C_7H_7.SO_2.CH_2Br$ (Otto, *J. pr.* [2] 40, 542).—AgA': trimetric tables.

Ethyl ether EtA'. Converted by bromine (2 mols.) at 90° into $C_7H_7.SO_2.CBr_2.CO_2Et$ which on saponification by cold NaOHAq yields $C_7H_7.SO_2.CHBr_2$ [117°].

***p*-TOLYL-SULPHONO-ACETONE** $CH_3.CO.CH_2.SO_2.C_6H_4Me$. [51°]. Formed by heating sodium toluene *p*-sulphinate with chloro-acetone in alcohol (Otto, *J. pr.* [2] 36, 425). Needles, v. sol. alcohol. Bromine forms $CH_2Br.CO.CH_2.SO_2C_7H_7$ [130°], m. sol. alcohol.

Di-*p*-tolyl-di-sulphono-acetone $CO(CH_2.SO_2.C_6H_4Me)_2$. Formed by heating $CH_2Br.CO.CH_2.SO_2C_7H_7$ with sodium toluene *p*-sulphinate in alcoholic solution. Plates, v. sol. hot HOAc and chloroform.

DI-TOLYL DI-SULPHONO-DI-ETHYL-AMINE $NH(C_2H_4.SO_2.C_7H_7)_2$. Formed by heating di-tolyl ethylene disulphone with NH_3Aq (Otto, *J. pr.* [2] 30, 359).—B'HCl. [201°].—$B'HAuCl_4$: dark-yellow needles.

DI-TOLYL-DI-SULPHONO-DI-ETHYL OXIDE $O(C_2H_4.SO_2.C_7H_7)_2$. [84°]. Formed by the action of conc. KOHAq on $C_2H_4(SO_2C_7H_7)_2$ and as a by-product in the preparation of $C_7H_7.SO_2.C_2H_4OH$ [55°] by the action of dilute KOHAq on the same body (Otto a. Tröger, *B.* 26, 944; *cf. J. pr.* [2] 30, 171, 321).

TOLYL DISULPHOXIDE *v. Tolyl ether of* Toluene thiosulphonic acid.

Di-*p*-tolyl sulphoxide $SO(C_6H_4Me)_2$. [92°]. Formed from toluene, $SOCl_2$, and $AlCl_3$ (Parker, *B.* 23, 1844). Flat needles (from ligroïn), v. e. sol. benzene. Reduced by sodium and alcohol to di-tolyl sulphide [56°]. $KMnO_4$ in HOAc forms di-tolyl sulphone [158°].

DI-*o*-TOLYL-TETRAZINE $C_{16}H_{16}N_4$ *i.e.* $C_7H_7N<\begin{smallmatrix}N:CH\\CH:N\end{smallmatrix}>NC_7H_7$. [141°]. Formed from *o*-tolyl-hydrazine, chloroform, and alcoholic potash (Ruhemann, *C. J.* 57, 52). Crystals. Yields crystalline $C_{16}H_{15}(SO_3H)N_4$ and $C_{16}H_{15}(NO_2)N_4$ [207°].—B'HCl: needles.

Methylo-iodide B'MeI. [198°]. Nodules.

Di-*p*-tolyl-tetrazine $C_{16}H_{16}N_4$. Formed in like manner. B'HCl: very unstable white needles.

Methylo-iodide B'MeI. [242°]. Needles.

***o*-TOLYL-THIAZOLE DIHYDRIDE** $C_6H_4Me.C<\begin{smallmatrix}N.CH_2\\S.CH_2\end{smallmatrix}$. (282°). Formed from thio-*o*-toluic amide and ethylene bromide (Gabriel a. Heymann, *B.* 24, 786). Got also by heating *o*-toluic bromo-ethyl-amide with P_2S_5 (Salomon, *B.* 26, 1329). Converted by bromine-water into taurine and *o*-toluic acid. — $B'_2H_2PtCl_6$. [199°].—$B'C_6H_3N_3O_7$. [132°].

***p*-Tolyl-thiazole dihydride.** [81°]. Prepared in like manner. Tables.

***p*-TOLYL-THIOBIURET** $C_9H_{11}N_3S_2$. [158°]. Formed by fusing *p*-toluidine (2 pts.) with persulphocyanic acid (1 pt.) (Tursini, *B.* 17, 584). Minute needles, sol. NaOHAq. Yields $C_9H_{10}N_3S_2Et$ [134°], crystallising from alcohol in needles, and $C_9H_{10}AcN_3S_2$ [166°], crystallising in needles.

***o*-TOLYL-β-THIOCARBAMIC ACID** [1:2]$C_6H_4Me.NH.CS.OH$.

Ethyl ether $C_7H_7N:C(SH).OEt$. *Tolyl-thiourethane.* Formed by heating *o*-tolyl-thiocarbimide with alcohol at 130° (Liebermann a. Natanson, *B.* 13, 1576; *A.* 207, 161). Oil, sol. alkalis.—$C_{10}H_{12}AgNSO$: white pp. insol. NH_3Aq. Converted by MeI into $C_7H_7N(OEt).SMe$, and by EtI into $C_7H_7N(OEt).SEt$, both being oils boiling above 250°.

***m*-Tolyl-β-thiocarbamic acid** [1:3]$C_6H_4Me.NH.CS.OH$.

Ethyl ether $C_7H_7N:C(SH).OEt$. [68°]. Formed in like manner (L. a. N.). Yields $C_{10}H_{12}AgNSO$ and oily $C_{10}H_{12}EtNSO$.

***p*-Tolyl-β-thiocarbamic acid.** *Ethyl ether* $C_7H_7NC(SH).OEt$. [87°]. Formed in the same way (L. a. N.). Triclinic crystals. Ammoniacal $AgNO_3$ added to its alcoholic solution ppts. $C_7H_7NC(OEt).SAg$, which is converted by MeI into $C_7H_7NC(OEt).SMe$, and by EtI into $C_7H_7NC(OEt).SEt$, both being oils boiling above 250°. $C_7H_7NC(OEt).SEt$ is decomposed by dilute H_2SO_4 at 180° into *p*-toluidine and thiocarbonic ether.

***o*-Tolyl-α-thiocarbamic acid** $C_7H_7NH.CO.SH$.

Methyl ether MeA'. [70°]. Formed by heating $C_7H_7NH.C(NC_7H_7).SMe$ with dilute H_2SO_4 at 140° (Will a. Bielschowski, *B.* 15 1317). Plates.

Ethyl ether EtA'. [60°]. Tables.

***p*-Tolyl-α-thiocarbamic acid** $NHC_7H_7.CO.SH$.

Methyl ether MeA'. [107°]. Formed by heating $C_7H_7NH.C(NC_7H_7).SMe$ with dilute H_2SO_4 at 170°. Needles, v. sol. alcohol and ether.

Ethyl ether EtA'. [79°]. Formed from *p*-toluidine and Cl.CO.SEt. Needles. Yields EtSH and tolyl cyanate on distillation.

Ethylene derivative  $CO<\begin{smallmatrix}N(C_7H_7)\\S\end{smallmatrix}>C_2H_4$. [88°]. Long slender needles.

***o*-Tolyl-di-thio-carbamic acid** $C_7H_7NH.CS.SH$.—NiA'_2. Brown needles, insol. water.—BaA'_2. Plates (Losanitsch, *B.* 24, 3027). Forms di-*o*-tolyl-thio-urea on heating.

Methyl ether MeA'. [132°]. Formed from the Ba salt and MeI. White needles.

Ethyl ether EtA'. [72°]. Formed by heating $C_7H_7NH.C(NC_7H_7).SEt$ with CS_2 at 160° (Will a. Bielschowski, *B.* 15, 1317). Prisms.

Ethylene derivative $C_{10}H_{11}NS_2$ *i.e.*  $CS<\begin{smallmatrix}N(C_7H_7)\\S\end{smallmatrix}>C_2H_4$. [129°]. Formed by heating  $C_7H_7N.C<\begin{smallmatrix}S\\NC_7H_7\end{smallmatrix}>C_2H_4$ with CS_2 at 200°. Yields $C_{10}H_{11}NS_2MeI$, crystallising in prisms [151°].

***m*-Tolyl-di-thio-carbamic acid** $C_7H_7NH.CS.SH$.

Salts.—BaA'_2. Formed from *m*-toluidine, CS_2, and $Ba(OH)_2$ in alcohol (Losanitsch, *B.* 24, 3027). Needles, sol. water, insol. cold alcohol.—NiA'_2. Yellowish-brown plates.

Methyl ether MeA'. [89°]. Needles.

***p*-Tolyl-di-thio-carbamic acid** $C_7H_7NH.CS_2H$.

Salts.—NH_4A'. Formed from *p*-toluidine, CS_2, alcohol, and NH_3Aq (Losanitsch, *B.* 24, 3026). Yellowish prisms, sol. water, insol. alcohol.—BaA'_2. Needles.—NiA'_2. Formed from *p*-toluidine, CS_2, ammoniacal $NiSO_4$, and alcohol. Brown needles, sol. alcohol, insol. water.

Methyl ether MeA'. [84°]. Prisms.

Ethyl ether EtA'. [74°]. Formed by heating $NHC_7H_7.C(NC_7H_7).SEt$ with CS_2 at 160° (W. a. B.). Needles, split up by heat into *p*-tolyl thiocarbimide and EtSH.

Ethylene ether  $CS<\begin{smallmatrix}N(C_7H_7)\\S\end{smallmatrix}>C_2H_4$. [126°]. Crystals. Yields a methylo-iodide [107°], which is converted by aniline into $C_{16}H_{18}N_2S$ [128°], and by *o*-toluidine into $C_{17}H_{18}N_2S$ [82°].

Reference. — NITRO-TOLYL-THIOCARBAMIC ETHER.

***o*-TOLYL-THIOCARBAZIC ACID** *o-Tolyl hydrazide* $C_7H_7NH.NH.CS.SNH_3.NHC_7H_7$. Formed from *o*-tolyl-hydrazine, ether, and CS_2 (Freund, *B.* 24, 4200). Prismatic tables, insol. ether, decomposed by water and alcohol. The *p*-isomeride melts at 109°.

DI-*o*-TOLYL-THIOCARBAZIDE $C_{15}H_{18}N_4S$ *i.e.* $CS(NH.NHC_6H_4Me)_2$. [130°]. Formed from *o*-tolyl-thiocarbazic acid and *o*-tolyl-hydrazine at 90° (Freund, *B.* 24, 4201). Needles, sol. alcohol, insol. Aq.

Di-*p*-tolyl-thiocarbazide. [121°]. Formed in like manner at 110° (Freund, *B.* 24, 4194). Plates, v. sol. hot alcohol.

Di-*o*-tolyl-thiosemicarbazide $C_{15}H_{17}N_3S$ *i.e.* $NHC_7H_7.CS.NH.NHC_7H_7$. [149°]. Formed by heating *o*-tolyl-thiocarbimide (1 mol.) with *o*-tolyl-hydrazine (1 mol.) in alcohol (Dixon, *C. J.* 61, 1017). Octahedra, m. sol. hot alcohol, insol. Aq.

Di-*p*-tolyl-thiosemicarbazide. [154°]. Formed in like manner (D.). Prisms, v. e. sol. hot alcohol.

_op_-Di-tolyl-thiosemicarbazide [4:1]$C_6H_4Me.NH.CS.NH.NHC_6H_4Me$[1:2]. [142°]. Formed from _p_-tolyl-thiocarbimide and _o_-tolylhydrazine (D.). Prisms, sl. sol. hot alcohol.

Isomeride [2:1]$C_6H_4Me.NH.CS.NH.NHC_6H_4Me$[1:4]. [163°]. Formed from _o_-tolyl-thiocarbimide and _p_-tolylhydrazine (Dixon, _C. J._ 61, 1015). Prisms, m. sol. hot alcohol.

DI-_o_-TOLYL-THIOCARBAZONE $C_{15}H_{16}N_4S$ _i.e._ $C_7H_7N:N.CS.NH.NHC_7H_7$. [168°]. Formed from di-_o_-tolyl-thiocarbazide and alcoholic potash (Preund, _B._ 24, 4201). Blue-black needles, v. sol. chloroform, sl. sol. alcohol. Conc. H_2SO_4 forms a bluish-green solution.

Di-_p_-tolyl-thiocarbazone. [105°]. Formed in like manner. Dark-blue amorphous flakes.

_o_-TOLYL-THIOCARBIMIDE C_8H_7NS _i.e._ [1:2]$C_6H_4Me.N:CS$. (239°). Formed from di-_o_-tolyl-thio-urea by distilling with P_2O_5 (Staats, _B._ 13, 136), by heating with aqueous H_3PO_4 (Hofmann, _B._ 15, 986; Mainzer, _B._ 16, 2017), or by boiling with fuming HClAq (Girard, _B._ 6, 445). Oil.

Reactions.—1. _Chlorine_ forms $C_7H_7.NCl.CSCl$ (218°), which is converted by alcohol into a mixture of di-_o_-tolyl-urea and _o_-tolyl-carbamic ether (Lachmann, _B._ 12, 1349).—2. _Chloro-acetic acid_ and alcohol at 150° form  $C_7H_7.N:C<\begin{matrix}S.CH_2\\O.CO\end{matrix}$ crystallising in needles [120°], decomposed by boiling baryta-water into _o_-toluidine, CO_2, and thioglycollic acid (Völtzkoff, _B._ 13, 1580).—3. PhOMe and $AlCl_3$ on warming form $C_7H_7NH.CS.C_6H_4OMe$ [95°] (Tust a. Gattermann, _B._ 25, 3528). PhOEt and $AlCl_3$ give $C_{16}H_{17}NSC$ [116°].

_m_-Tolyl-thiocarbimide $C_7H_7.N:CS$. (244°) at 732 mm. Formed by boiling di-_m_-tolyl urea with conc. HClAq (Weith a. Landolt, _B._ 8, 719). Heavy oil. Converted by copper-powder at 220° into _m_-toluic nitrile.

_p_-Tolyl-thiocarbimide [1:4] $C_6H_4Me.N:CS$. [26°]. (237°). Formed by heating di-_p_-tolyl-thio-urea with P_2O_5 or aqueous H_3PO_4 of S.G. 1·7 (Hofmann, _B._ 1, 173; 15, 986; Staats, _B._ 13, 135). Formed also, together with phenyl-thiocarbimide, by heating $PhN:C:NC_7H_7$ with CS_2 at 190° (Huhn, _B._ 19, 2409). Needles (from ether), v. sol. alcohol.

Reactions.—1. _Ammonia_ forms tolyl-thio-urea, and other bases act in like manner.—2. _Bromine_ forms $C_7H_7NBr.CSBr$, which readily gives off Br_2 leaving $(C_7H_7NCS)_2Br_2$ crystallising in plates decomposing at 210° (Helmers, _B._ 20, 790).—2. _Chlorine_ forms $(C_7H_7NCS)_2Cl_2$, whence dilute alcohol gives $(C_7H_7NCS)_2O$ [139°], crystallising in needles.—3. $CH_2Cl.CO_2H$ and alcohol at 150° form  $C_7H_7N:C<\begin{matrix}S.CH_2\\O.CO\end{matrix}$ [162°] (Völtzkoff, _B._ 13, 1579).—4. Warmed with toluene and $AlCl_3$ it gives $C_7H_7NH.CS.C_7H_7$ [166°].—5. Heated with $AlCl_3$ it yields $(C_7H_7N.CS)_2S$ [176°] (Friedmann a. Gattermann, _B._ 25, 3525). 6. C_6H_5OMe and $AlCl_3$ react, with formation of $C_7H_7NH.CS.C_6H_4.OMe$ [157°].—7. C_6H_5OEt and $AlCl_3$ give $C_{16}H_{17}NOS$ [151°], which may be oxidised to $C_{16}H_{15}NOS$ [170°].

DI-_p_-TOLYL DI-THIO-CARBONATE $CO(SC_6H_4Me)_2$. [91°]. Formed from _p_-tolyl mercaptan and $COCl_2$. It is also a by-product in the action of _p_-diazo-toluene chloride on potassium xanthate (Leuckart, _J. pr._ [2] 41, 190). Needles (from alcohol).

TRI-TOLYL TRI-THIOCYANURATE $(C_6H_4Me.SCy)_3$. [114°]. Formed from sodium _p_-tolyl mercaptan and cyanuric chloride (Klason, _J. pr._ [2] 33, 120). Crystals (from HOAc).

_o_-TOLYL-THIOHYDANTOÏN $C_9H_{10}NSO$ _i.e._  $CS<\begin{matrix}N(C_6H_4Me)\\NH.CH_2\end{matrix}>CO$. [136°]. Formed from _o_-tolyl-thiocarbimide and amido-acetic acid (Marckwald, _B._ 24, 3281). Plates, v. sol. alcohol, sl. sol. ligroïn.

_p_-Tolyl-thiohydantoïn [210°] (M.). Formed as above (M.; _cf._ Aschan, _B._ 17, 426). Flat prisms, sol. alkalis.

Isomeride [183°]. Formed by fusing $CH_2Cl.CO.NHC_7H_7$ with thio-urea (P. Meyer, _B._ 10, 1966). Small crystals.

_p_-Tolyl-ψ-thiohydantoic acid $C_7H_7N:C(NH_2).S.CH_2.CO_2H$. [176° – 182°]. Formed by boiling chloro-acetic acid with ammonium sulphocyanide, _p_-toluidine, and alcohol (Jäger, _J. pr._ [2] 16, 21). Prisms, not attacked by Ac_2O and Br.

DI-_p_-TOLYL-THIOPHENE $C_{18}H_{16}S$ _i.e._  $\begin{matrix}CH:C(C_6H_4Me)\\CH:C(C_6H_4Me)\end{matrix}>S$. [171°]. Formed by heating di-_p_-tolyl-furfurane with P_2S_5 (Hollemann, _R. T. C._ 6, 74). Small plates (from alcohol). Gives an intense dark-green colour with isatin and H_2SO_4.

_o_-TOLYL-THIO-UREA $NH_2.CS.NHC_6H_4Me$. [155°]. Formed from _o_-tolyl thiocarbimide and NH_3Aq (Staats, _B._ 13, 136). V. sol. hot water and alcohol, sl. sol. ether.

Acetyl derivative $NHAc.CS.NHC_6H_4Me$. [184°]. Formed from acetyl thiocarbimide and _o_-toluidine in alcohol (Dixon, _C. J._ 55, 804). Pale lemon-yellow prisms, insol. water, sol. alcohol.

Benzoyl derivative $NHBz.CS.NHC_6H_4Me$. [119°]. Formed in like manner (Dixon, _C. J._ 55, 623). Pale-yellow prisms, blackened by $AgNO_3$.

Di-_o_-tolyl-thio-urea $CS(NH.C_6H_4Me)_2$. [158°]. Formed from _o_-toluidine and CS_2 (Girard, _B._ 4, 985; Berger, _B._ 12, 1854; Ador a. Rilliet, _B._ 12, 2301). Long needles, v. sol. hot alcohol. Converted by heating with MeI into the hydroiodide of di-tolyl-methyl-thiourea $C_{16}H_{18}N_2S$, which may be represented as 'methyl di-_o_-tolyl-imido-thiocarbamate' $C_7H_7N:C(SMe).NHC_7H_7$. This body melts at 60°, while the corresponding ethyl derivative melts at 51°. The ethylene derivative [91°] may be represented by the formula  $C_7H_7N:C<\begin{matrix}N(C_7H_7)\\S\end{matrix}>C_2H_4$ (Will a. Bielschowski, _B._ 15, 1316). The isomeric compound  [1:2]$C_6H_4Me.N:C<\begin{matrix}N(C_6H_4Me[1:4])\\S.C_2H_4\end{matrix}>$ [82°] is got by boiling the methylo-iodide of the ethylene derivative of _p_-tolyl-di-thio-carbamic acid with _o_-toluidine.

_m_-Tolyl-thio-urea $NHC_7H_7.CS.NH_2$. [103°]. Formed from _m_-tolyl thiocarbimide and ammonia (Weith a. Landolt, _B._ 8, 719). Prisms, m. sol. hot water, v. sol. alcohol and ether.

Di-_m_-tolyl-thio-urea $CS(NHC_7H_7)_2$. [122°]. Formed from _m_-toluidine, CS_2, and alcohol (W.

a. L.). Needles, v. sol. alcohol, nearly insol. hot water.

p-Tolyl-thio-urea $NHC_7H_7.CS.NH_2$. [188°]. (C. a. W.); [182°] (S.). Formed by heating *p*-toluidine hydrochloride with ammonium sulphocyanide (De Clermont a. Wehrlin, *C. R.* 83, 347). Formed also from *p*-tolyl-thiocarbimide ammonia (Staats, *B.* 18, 136). Plates (from alcohol) with bitter taste, sl. sol. cold water, m. sol. alcohol.

Acetyl derivative $NHC_7H_7.CS.NHAc$. [176°]. Formed from acetyl sulphocyanide and *p*-toluidine (Miguel, *Bl.* [2] 28, 103). Needles, v. e. sol. hot alcohol, v. sol. ether.

Di-*p*-tolyl-thio-urea $CS(NHC_6H_4Me)_2$. [176°]. Formed by boiling *p*-toluidine with CS_2 and alcohol (Sell, *A.* 126, 160). It is also a product of the action of allyl-thiocarbimide on an alcoholic solution of *p*-toluidine (Maly, *Z.* [2] 5, 258). Trimetric prisms (Levin, *J.* 1882, 384), insol. water, nearly insol. cold alcohol. In alcoholic solution it is converted by HgO into di-*p*-tolyl-urea. In benzene solution $COCl_2$ forms $C_{16}H_{14}N_2SO$ [116°] (Will, *B.* 14, 1487). $CSCl_2$ forms $C_{16}H_{14}N_2S_2$ [109°] (Freund a. Wolf, *B.* 25, 1465). MeI forms $C_7H_7N{:}C(NHC_7H_7).SMe$ [128°], crystallising in needles, split up by heat into $C(NC_7H_7)_2$ [60°] and HSMe, converted by heating with acids or alkalis into di-*o*-tolyl-urea and MeSH, and forming the salts B'HCl [173°] and $B'H_2SO_4$ [156°]. EtI forms the corresponding $C_{17}H_{20}N_2S$ [87°], while ethylene bromide gives  $C_7H_7N{:}C\left\langle\begin{matrix}N(C_7H_7)\\S.C_2H_4\end{matrix}\right\rangle$ [112°], which yields $B'H_2SO_4$ [194°] and a hydrochloride [219°] (Will a. Bielschowski, *B.* 14, 1492; 15, 1309).

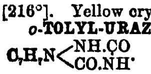
References.—NITRO- and OXY- TOLYL-THIO-UREA.

p-TOLYL - TOLUTRIAZINE DIHYDRIDE $C_{15}H_{15}N_3$ *i.e.*

$$\begin{matrix}CH:CH.C.N.CH_2\\CMe:CH.C.N.NC_6H_4Me\end{matrix}$$

[178°]. Formed by heating *o*-amido-azo-toluene with formic paraldehyde and alcohol at 140° (Goldschmidt a. Poltzer, *B.* 24, 1008). Prisms, v. sol. hot alcohol.—B'HCl. [220°].—$B'_2H_2PtCl_6$. [216°]. Yellow crystalline pp.

***o*-TOLYL-URAZOLE** $C_9H_9N_3O_2$ *i.e.*



$$C_7H_7N\left\langle\begin{matrix}NH.CO\\CO.NH\end{matrix}\right.$$

[170°]. Got by heating *o*-tolyl-hydrazine hydrochloride with urea (Pinner, *B.* 21, 1219). White leaflets, v. sol. hot water.

***p*-Tolyl-urazole.** [274°]. Yellowish needles, v. sl. sol. hot water.

***o*-TOLYL-UREA** $C_8H_{10}N_2O$ *i.e.* $NH_2.CO.NH.C_6H_4Me$ [1:2]. [185°]. Formed from *o*-toluidine hydrochloride and potassium cyanate (Cosack, *B.* 18, 1089). Plates, sol. alcohol, ether, and hot water.

Benzoyl derivative $CO(NHBz).NHC_7H_7$. [210°]. Formed from *o*-tolyl cyanate and benzamide at 125° (Gattermann a. Cantzler, *B.* 25, 1088). Needles.

***m*-Tolyl-urea** $NH_2.CO.NHC_6H_4Me$ [1:3]. [142°]. Formed from *m*-toluidine hydrochloride and potassium cyanate (Cosack, *B.* 12, 1450; 18, 1089). Needles or tables (from alcohol) or plates (from water).

***p*-Tolyl-urea** $NH_2.CO.NHC_6H_4Me$ [1:4]. [172°] (C.); [180°] (St.; P.). Formed in like manner (C.; *cf.* Sell, *C. J.* 16, 190). Formed also by the action of *p*-toluidine on mercuric fulminate (Steiner, *B.* 8, 519), and also from *p*-toluamidoxim, benzene sulphonic acid, NaOH, and $CHCl_3$ (Pinnow, *B.* 24, 4167). Needles, sol. hot water, v. sl. sol. ligroïn.

Di-*o*-tolyl-urea $CO(NHC_7H_7)_2$. [246°] (B.); [254°] (W.); [256°] (Barr, *B.* 19, 1769).

Formation.—1. By the action of alcohol or water at 100° on the dichloride of *o*-toluic nitrile (Lachmann, *B.* 12, 1349).—2. From *o*-toluidine hydrochloride and cyanamide (Berger, *B.* 12, 1859).—3. From tolyl cyanate and water (Nevile a. Winther, *B.* 12, 2325).—4. From *o*-toluidine and $COCl_2$ (Girard, *B.* 6, 444).—5. By heating *o*-toluidine with urea (G.).—6. A product of the distillation of *o*-tolyl-amido-acetic acid (Widman, *J. pr.* [2] 38, 303).—7. By the action of Ac_2O and benzene on the *o*-toluide of *o*-tolyl-imido-diacetic acid (Bischoff, *B.* 23, 1995).

Properties.—Needles (from HOAc), insol. ether, sl. sol. alcohol. Not volatile with steam.

Di-*m*-tolyl-urea $CO(NH.C_6H_4Me)_2$. [203°] (G. a. C.); [217°] (C.). Formed from *m*-tolyl cyanate and *m*-toluidine (Gattermann a. Cantzler, 25, 1089), by the action of $ClCO_2Et$ on *m*-toluidine, by heating *m*-tolyl-carbamic ether with water, and by heating *m*-tolyl-urea with *m*-toluidine at 160° (Cosack, *B.* 12, 1450; 13, 1090). Needles (from alcohol), insol. water.

Di-*p*-tolyl-urea $CO(NH.C_6H_4Me)_2$. [255°].

Formation.—1. By boiling an alcoholic solution of di-*p*-tolyl-thio-urea with HgO as long as HgS is formed (Sell, *C. J.* 16, 190; *A.* 126, 161).—2. By passing $COCl_2$ into *p*-toluidine dissolved in chloroform (Michler, *B.* 9, 710; Kühn, a. Henschel, *B.* 21, 505).—3. By heating tolyl-urea with *p*-toluidine at 160° (Weith, *B.* 9, 821). 4. From *p*-tolyl-cyanate and *p*-toluidine (Gattermann a. Cantzler, *B.* 25, 1089).

Properties.—Needles, insol. water, sl. sol. cold alcohol.

Tri-*p*-tolyl-urea $C_{22}H_{22}N_2O$. [189°]. Got from $(C_7H_7)_2N.COCl$ and *p*-toluidine (Hammerich, *B.* 25, 1822). Needles, sol. warm benzene, insol. ether. Gives a benzoyl derivative [137°].

Tetra-*p*-tolyl-urea $C_{29}H_{28}N_2O$. [80°]. Got from $(C_7H_7)_2N.COCl$ and di-*p*-tolyl-amine. Needles, v. e. sol. alcohol.

References.—AMIDO-, NITRO-, and OXY-TOLYL-UREA.

TOLYL-XYLIDINE $C_{15}H_{17}N$ *i.e.* $C_6H_4Me.NH.C_6H_3Me_2$. [70°]. (c. 300° at 487 mm.). Silky needles (from alcohol) (Girard a. Vogt, *Bl.* [2] 18, 69).

***o*-TOLYL *m*-XYLYL KETONE** $C_{16}H_{16}O$ *i.e.* [1:2] $C_6H_4Me.CO.C_6H_3Me_2$ [1:2:3]. (330°) at 728 mm. Formed from *o*-toluic chloride and *m*-xylene (Smith, *B.* 24, 4050). Oil. Converted by hydroxylamine at 120° into a mixture of anilides.

TONKA BEANS, the fruit of *Dipterix odorata*, contains coumarin (*q. v.*) (Boullay a. Boutron-Charlard, *J. Ph.* 11, 426; [3] 7, 160).

TRAGACANTH GUM. Exudes from *Astragalus verus*, a tree growing in Armenia and the north of Persia. It swells up in water, about one-half of it dissolving. It contains arabin, bassorin, starch, and water.

TRANSPIRATION. Graham, in 1846 and 1849, applied the term 'transpiration' to the passage of gases through capillary tubes into a

vacuum (*v. T.* 1846. 573; 1849. 349). The rates of transpiration of different gases bear constant relations to each other; but these rates have not been connected in any definite ways with the compositions of the gases. M. M. P. M.

TREE GUM *v.* XYLAN.

TREHALOSE *v.* SUGAR.

TREHALUM $C_{24}H_{42}O_{21}$. S. ·06 at 17°; 1·8 at 100°. $[\alpha]_D = +179°$. Occurs in *Trehala manna* (Scheibler a. Mittelmeier, *B.* 26, 133[illegible]). Tasteless, minute prisms. Very hygroscopic. Does not reduce Fehling's solution. Does not react with phenyl-hydrazine. Boiling dilute H_2SO_4 forms glucose. At 180° it slowly forms trehalin, which is v. sol. water and ppd. by alcohol. Trehalin dissolves in phenyl-hydrazine. Iodine colours trehalum and trehalin violet. Diastase, yeast, and invertin have no action. Ac_2O and NaOAc yield an acetyl derivative [above 240°].

TRI-. In the alphabetical arrangement of this dictionary the prefix 'tri,' when indicating the presence of three radicles, is treated as if it did not form part of a name, except where the entire name is numerical, as in 'tridecane.'

TRIANOSPERMIN. A crystalline substance occurring in *Trianosperma ficifolia*, a climbing plant of Brazil (Peckholt, *Ar. Ph.* [2] 113, 104; Parodi, *Ph.* [3] 10, 667). It has a pungent taste, is alkaline in reaction, sol. water, alcohol, and ether, and is ppd. by $Pb(OAc)_2$ and $PtCl_4$.

TRIAZOLE  $N{<}\begin{matrix}CH{:}N\\ CH.NH\end{matrix}$. *Pyrrodiazole.* [120·5°]. (260°). V.D. 2·39 (calc. 2·49). Formed by heating its carboxylic acid alone or with boiling water (Andreocci, *B.* 25, 229; Bladin, *B.* 25, 745). Needles (from ether), v. sol. water and alcohol, may be sublimed. The di-oxy- derivatives of alkyl-triazoles  $N{<}\begin{matrix}C(OH){:}N\\ C(OH).NR'\end{matrix}$, named by Pinner 'urazoles,' are obtained by heating hydrazines with urea (Pinner, *B.* 20, 2358).

TRIAZOLE CARBOXYLIC ACID  $N{<}\begin{matrix}CH{=\!=}N\\ C(CO_2H).NH\end{matrix}$. [137°]. Obtained by oxidising methyl-triazole (Andreocci, *B*, 25, 229) or amido-phenyl-triazole carboxylic acid and alkaline $KMnO_4$ (Bladin, *B.* 25, 744). Amorphous powder.—CuA'_2aq. Green crystalline powder.

TRICARBALLYLIC ACID *v.* vol. i. p. 679.

TRICOSANE *v.* TRI-ICOSANE.

TRIDECANE $C_{13}H_{28}$. [−6°]. (234°). S.G. $\frac{0}{4}$ ·771; $\frac{15}{4}$ ·761. Formed by reduction of methyl dodecyl ketone or of tridecoic acid by HI and P (Krafft, *B.* 15, 1699). Formed also by distilling barium myristate with NaOMe (Mai, *B.* 22, 2184).

TRIDECOIC ACID $C_{12}H_{25}.CO_2H$. [41°]. (236° at 100 mm.). Formed by oxidation of methyl tridecyl ketone (Krafft, *B.* 12, 1669). Crystals. —AgA'.

Amide $C_{12}H_{25}.CO.NH_2$. [98·5°]. Formed by digesting the nitrile with conc. H_2SO_4 and pouring into water (Lutz, *B.* 19, 1439). Plates (from alcohol).

Nitrile $C_{12}H_{25}CN$. (275°). Formed from tridecylamine, Br, and NaOH. Oil, v. sol. alcohol and ether.

TRIDECYL ALCOHOL $(C_6H_{13})_2CH.OH$. [42°]. Formed by reducing di-hexyl ketone (Kipping, *C. J.* 57, 536). Plates (from dilute alcohol), insol. water. May be distilled. HBr forms $(C_6H_{13})_2CHBr$ [39°].

TRIDECYLAMINE $C_{13}H_{27}NH_2$. [27°]. (265°). Formed by boiling myristyl-tridecyl-urea with KOHAq (Lutz, *B.* 19, 1437). Unctuous mass, v. sol. alcohol and ether. Absorbs water and CO_2 from the air.—B'HCl: needles, decomposing at 100°.—$B'_2H_2PtCl_6$.—$B'_2H_2SO_4$: needles, insol. cold water.

TRIDECYLENE $C_{13}H_{26}$. (233° cor.). S.G. ^{0} ·8445. Occurs in petroleum from Burmah (Warren a. Storer, *Z.* 1868, 232).

TRIDECYL-UREA. *Myristyl derivative* $C_{28}H_{56}N_2O_2$ *i.e.* $C_{13}H_{27}NH.CO.NHC_{11}H_{27}O$. [103°]. Formed by the action of Br and KOHAq on the amide of myristic acid (Reimer a. Will, *B.* 18, 2016). Crystals (from alcohol), almost insol. cold water, sol. ether.

TRIGENIC ACID *v.* ETHYLIDENE-BIURET.

TRIGONELLIN $C_7H_7NO_2$ *i.e.*

. Occurs in the seeds of *Trigonella Fœnum-græcum* (Jahns, *B.* 18, 2518; 20, 2840). It is also produced by saponification of the product of the reaction of MeI on potassium pyridine (β)-carboxylate (Hantzsch, *B.* 19, 31). Colourless prisms (containing aq), converted by HClAq at 265° into pyridine (β)-carboxylic acid (*q. v., Reaction* 4).—B'HCl.—$B'_2H_2PtCl_6$.—$B'HAuCl_4$ [198°].—$B'_4 3HAuCl_4$. [186°]. Slender needles.

***n*-TRI-ICOSANE** $C_{23}H_{48}$. [48]. (234° at 15 mm.). S.G. $\frac{48}{4}$ ·7785; $\frac{81}{4}$ ·7570. Formed from laurone $(C_{11}H_{23})_2CO$ by treatment with PCl_5 and reduction of the resulting $(C_{11}H_{23})_2CCl_2$ with HI and P at 240° (Krafft, *B.* 15, 1712). Obtained also by fractional distillation of paraffin oil from brown coal (Krafft, *B.* 21, 2263). Glittering plates (from ether-alcohol), sl. sol. alcohol.

TRI-ICOSANE DICARBOXYLIC ACID $C_{23}H_{46}(CO_2H)_2$. [102·5°]. Formed by heating di-oxy-penta-icosylene with soda-lime (Stärcke, *A.* 223, 300). Flocculent pp. (from ligroïn-ether). —PbA''.

TRI-ICOSYL ALCOHOL $(C_{11}H_{23})_2CH.OH$. [76°]. Formed by reducing laurone with Na and water (Kipping, *C. J.* 57, 983). Plates (from ether), insol. water. Yields an acetyl derivative $(C_{11}H_{23})_2CH.OH$ [35°].

TRI-ICOSYL ALCOHOL $C_{23}H_{47}.OH$. [82°]. A wax-like body extracted by hot alcohol from flax fibres (Cross a. Bevan, *C. N.* 59, 135). Yields an acetyl derivative [65°].

TRIMELLITIC ACID *v.* vol. iii. p. 201.

TRIMESIC ACID *v.* vol. iii. p. 230.

TRIMESITIC ACID *v.* PYRIDINE TRICARBOXYLIC ACID.

TRIMETHYLENE *v.* vol. iii. p. 304.

TRITICIN $C_{12}H_{22}O_{11}$. $[\alpha]_D = -43·6°$ (Reidemeister, *J. Th.* 1881, 69). Extracted by dilute alcohol from the root of couch-grass (*Triticum repens*) (H. Müller, *Ar. Ph.* [3] 2, 500; 3, 1). Tasteless hygroscopic powder, v. sol. water, insol. alcohol and ether. Lævorotatory. On boiling with water, especially in presence of acids, it changes into lævulose. Its solutions are not ppd. by metallic salts, nor coloured by iodine.

TROPÆOLINES *v.* AZO- COMPOUNDS.

TROPEÏNES. A name given by Ladenburg to alkoyl derivatives of tropine (*q. v.*).

TROPIC ACID *v.* OXY-PHENYL-PROPIONIC ACID.

TROPIDINE *v.* METHYL-ETHYLENE PYRIDINE TETRAHYDRIDE.

(α)-Methyl-tropidine $C_9H_{15}N$ *i.e.* $CH_2{:}CH.CH{:}CH.CH{:}CH.CH_2.NMe_2$ (Ladenburg) or

$CH{<}\begin{matrix}CH{:}CH\\CH.CH_2\end{matrix}{>}CH.CH_2.NMe_2$ (Merling). Formed by distilling tropidine methylo-hydroxide with water (Roth, *B.* 17, 157; Merling, *B.* 24, 3118). Oil. HClAq forms 'hydrochloro-(α)-methyl-tropidine' which gradually changes into the isomeric tropidine methylo-chloride. — $B'_2H_2PtCl_6$. [174°].—$B'HAuCl_4$: golden-yellow pp.

Methylo-iodide B'MeI. [162°]. Needles.

(β)-Methyl-tropidine $C_9H_{15}N$. (205°). S.G. 15 ·922. Formed by heating (α)-methyl-tropidine at 150°–200°. Oil. Converted by HCl into tropilene.

TROPIGENIN $C_7H_{13}NO$. [161°]. Got by oxidation of tropine by alkaline $KMnO_4$ (Merling, *B.* 15, 287). Got also by boiling 'homohydro-apotropine' with baryta-water (Pesci, *G.* 12, 329). Needles, sol. water and alcohol. Reconverted by MeI into tropine. Oxidised by chromic acid mixture to ecgonic acid and a small quantity of tropic acid (Liebermann, *B.* 24, 615).—B'HI.—B'_2CO_2: crystalline pp. — $B'_2H_2PtCl_6$ aq. — $B'HAuCl_4$: golden-yellow plates, sol. alcohol.

TROPILENE $C_7H_{10}O$ *i.e.*

$CH_2{<}\begin{matrix}CH{:}CH\\CH_2.CH_2\end{matrix}{>}CH.CHO$ (?) (Merling) (182°) (L.); (187°) (M.). S.G. $\frac{0}{}$ 1·0091. V.D. 102·3 (calc. 110). Formed by distilling tropidine methylo-iodide with KOH (Ladenburg, *B.* 14, 2403; 15, 1028; *A.* 217, 138). Formed also from (β)-methyl-tropidine and cold HClAq (Merling, *B.* 24, 3123). Oil, smelling like oil of bitter almonds and acetone, sol. dilute HClAq, v. sol. alcohol and ether. Reduces warm ammoniacal $AgNO_3$, forming a mirror. Reduces Fehling's solution and $KMnO_4$ in the cold. Not attacked by AcCl. Combines with $NaHSO_3$ (M.). Nitric acid forms an adipic acid $C_6H_{10}O_4$. Slowly combines with methylamine, forming (β)-methyl-tropine.

TROPILIDENE C_7H_8 *i.e.*

$CH{<}\begin{matrix}CH{:}CH\\CH.CH_2\end{matrix}{>}C{:}CH_2$. (114°). S.G. $\frac{0}{4}$ ·9129. Formed by distilling methyl-tropine methylo-iodide with KOH (Ladenburg, *A.* 217, 133; *B.* 14, 2403; 26, 1067). Formed also, together with methylamine, by distilling tropine with soda-lime. Oil, smelling somewhat like toluene, but combining readily with bromine, forming $C_7H_8Br_2$. Gives no pp. with ammoniacal Cu_2Cl_2. Oxidised by CrO_3 to benzoic aldehyde and acid (Merling, *B.* 24, 3122).

TROPINE $C_8H_{15}NO$ *i.e.*

$\begin{matrix}CH.CH_2.CH.CH_2.CH_2.OH\\CH.CH_2.NMe\end{matrix}$ (Ladenburg) or

$\begin{matrix}CH_2.CH\\CH_2.CH\end{matrix}{>}C_2H_2OH\begin{matrix}CH_2\\NMe\end{matrix}$ (Merling). *Methyl-oxy-*

not absorb CO_2

tion ppts. metallic oxides from their salts. Not attacked by nitrous acid. Not volatile with steam. According to Eykman (*B.* 26, 1400) the refractive index agrees best with Merling's formula.

Reactions.—1. Decomposed by distilling with soda-lime into tropilidene, methylamine, and H_2O.—2. Loses H_2O, being converted into tropidine by heating with fuming HCl and HOAc at 180° or by heating with H_2SO_4 (1 pt.) and water (1½ pts.) at 230°.—3. Conc. HIAq and red P at 150° form tropidine and tropidine periodide, but at 140° they form '**tropine iodide**' $C_8H_{17}NI_2$ which crystallises from water in prisms [115°], whence silver chloride followed by $PtCl_4$ give $(C_8H_{17}NICl)_2PtCl_4$ crystallising in red octahedra. By treatment with Ag_2O followed by HCl and $PtCl_4$ very soluble $(C_8H_{17}NCl_2)PtCl_4$ is got.—4. Alkaline $KMnO_4$ forms tropigenin and, finally, oxalic acid and NH_3 (Merling, *A.* 216, 341).—5. CrO_3 forms tropinic acid $C_6H_{11}N(CO_2H)_2$.—6. Aqueous HOCl yields prisms [111°], whence alcohol produces $C_6H_5NCl_4.CH.OH$ [108°], which forms a hydrochloride [162°] crystallising in plates (Einhorn a. Fischer, *B.* 25, 1391).

Salts. — B'HCl. —$B'_2H_2PtCl_6$. Orange-red monoclinic crystals. [200°] (Schmidt, *A.* 208, 214).—$B'HAuCl_4$. [212°].—$B'HCl6HgCl_2$. [246°] (Ladenburg, *B.* 24, 1631).—$B'C_6H_3N_3O_7$.

Nitroxyl derivative $C_8H_{14}(ONO_2)N$. *Nitro-tropeïn.* Formed by warming tropine (2 g.) with HNO_3 (12 g. of S.G. 1·25) at 100° (Ladenburg, *B.* 15, 1025). Alkaline liquid, sol. water, alcohol, and ether. Yields KNO_2 on boiling with KOH.—$B'_2H_2PtCl_6$. Needles.—B'HI. Prisms.

Benzoyl derivative $C_8H_{14}(OBz)N$. *Benzoyl-tropeïne.* Formed by heating tropine hydrochloride with benzoic acid and dilute HCl (Ladenburg, *B.* 13, 1083; *A.* 217, 96). Crystallises as $C_{15}H_{19}NO_2$ 2aq [58°], $C_{15}H_{19}NO_2$ ⅓aq [37°], or anhydrous [42°]. Sl. sol. water, v. sol. alcohol and ether.—$B'HNO_3$.—$B'_2H_2PtCl_6$ 2aq.—$B'C_6H_3N_3O_7$.

o-Oxy-benzoyl derivative $C_8H_{14}(O.CO.C_6H_4.OH)N$. *Salicyl-tropeïne.* Formed in like manner, using salicylic acid (Gaebe a. Caro, *B.* 13, 106; L.). Silky plates. Feeble poison, ·025 g. killing a frog in a few hours. Has no apparent effect on the pupil.—B'HCl.—$B'H_2PtCl_6$.—$B'HAuCl_4$: yellow plates.

m-Oxy-benzoyl derivative $C_{15}H_{19}NO_3$. [226°]. Small plates, v. sl. sol. water. Acts slightly on the pupil of the eye.—B'HCl.—$B_{12}H_2SO_4$ 4aq.—$B'_2H_2PtCl_6$: orange plates.

p-Oxy-benzoyl derivative $C_{15}H_{19}NO_3$. [227°]. Trimetric plates (containing 2aq).—$B'HNO_3$.—$B'_2H_2PtCl_6$ 2aq. Orange plates.

Phenyl-acetyl derivative $C_{16}H_{21}NO_2$ *i.e.* $C_8H_{14}N(O.CO.CH_2Ph)$. *Phenylacettropeïne.* Aromatic oil.—B'HBr.—$B'_2H_2PtCl_6$.—$B'HAuCl_4$. —$B'_2H_2SO_4$. Soluble tables.

Mandelyl derivative $C_{16}H_{21}NO_3$ *i.e.* $C_8H_{14}N(O.CO.CHPh.OH)$. *Homatropine.* Formed by heating tropine with mandelic acid, HCl (1 pt.), and water (40 pts.), the yield being 50 p.c. of the theoretical amount (Ladenburg, *C. R.* 90, 921; *A.* 217, 82). Deliquescent prisms (from ether), sl. sol. water. A solution of its hydrochloride is ppd. by potassio-mercuric iodide, but not by tannin. It enlarges the pupil of the eye almost as energetically as atropine, but the enlargement passes off much more rapidly (Völkers,

A. 217, 86; Bertheau, *Berl. Klin. Wochenschrift*, 1880, No. 41; Tweedy a. Ringer, *Lancet*, 1880, No. 21).—$B'HBr$. Trimetric crystals; $a:b:c$ = ·414:1:·472.—$B'C_6H_3N_3O_7$. Yellow plates.—$B'HAuCl_4$.—$B'_2H_2SO_4$. Needles.

Cinnamoyl derivative $C_{17}H_{21}NO_2$. [70°]. Small plates (from dilute alcohol). Gives pps. with tannin, picric acid, potassio-mercuric iodide, and I in KI. Strong poison, ·03 g. killing a frog in three minutes. Has little action on the pupil. —$B'HCl$.—$B'_2H_2PtCl_6$.—$B'HAuCl_4$. Needles.

Atropyl derivative $C_{17}H_{21}NO_2$. *Atroptropeïne.* Oil.—$B'HAuCl_4$. Small needles.

Atrolactyl derivative $C_{17}H_{23}NO_3$. *Pseudo-atropine.* [120°]. Formed from atrolactic acid, tropine, and dilute HCl (1:400) by repeated evaporation (Ladenburg, *A*. 217, 87). Needles (from water). Resembles atropine in physiological action, two drops of a 1 p.c. solution expanding the pupil and paralysing accommodation for a week.—$B'HAuCl_4$. [114°].

Phthalyl derivative $C_{21}H_{22}N_2O_4$. [70°]. Formed, in very small quantity, by evaporating phthalic acid with tropine and dilute HCl. Mass of silky needles.—$B'H_2PtCl_6$.

Methylo-iodide $C_8H_{15}NOMeI$. Small crystals, nearly insol. alcohol. Yields $B'MeOH$ and $B'_2Me_2PtCl_6$ (Merling, *B*. 14, 1829; Ladenburg, *A*. 217, 131).

Ethylo-iodide $B'EtI$. Crystalline. Yields $B'_2Et_2PtCl_6$, a yellow crystalline powder.

(α)-Methyl-tropine $C_8H_{14}MeNO$. (243°). Formed by distilling tropine methylo-iodide. Liquid, v. sol. water and alcohol. Strongly alkaline. Its hydrochloride, distilled with solid KOH, yields dimethylamine.—$B'HAuCl_4$. Very unstable.

Methylo-iodide $(C_8H_{14}MeNO)MeI$. Deliquescent needles, decomposed by distilling with solid KOH into tropilidene and trimethylamine. —$(C_8H_{14}MeNO)_2Me_2PtCl_6$. Orange crystals.

(β)-Methyl-tropine $C_9H_{17}NO$. (198°-205°). Formed by shaking tropilene with an aqueous solution of dimethylamine (Ladenburg, *B*. 14, 2404). Liquid, split up by gaseous HCl into tropilene and NMe_2H.—$B'HAuCl_4$. Prisms.

(γ)-Methyl-tropine $C_9H_{17}NO$. Formed in small quantity by distilling the methylo-hydroxide of (α)-methyl-tropine (Merling, *B*. 15, 288). V. sl. sol. Aq.—$B'_2H_2PtCl_6$. V. sl. sol. Aq.

Metatropine $C_8H_{15}NO$. (238°). Formed by shaking tropine iodide with water and Ag_2O. Not solid at −30°.—$B'HCl$: tables.

Hydrotropidine $C_8H_{15}N$. (168°). S.G. ^{0} ·937; ^{15} ·926. Formed by reducing tropine iodide $C_8H_{15}NI_2$ with zinc-dust and HClAq (Ladenburg, *B*. 16, 1408). Liquid, m. sol. water.—$B'HCl$: deliquescent crystals.—$B'_2H_2PtCl_6$. Tables.

Norhydrotropidine $C_7H_{13}N$. [60°]. (161°). Formed by distilling hydrotropidine hydrochloride in a current of HCl (Ladenburg, *B*. 20, 1649). Crystalline.—$B'HCl$. [281°].—$B'_2H_2PtCl_6$.—$B'HHgCl_3$.—$B'C_6H_3N_3O_7$. Needles.

Nitrosamine $C_7H_{12}N_2O$. [117°]. Cubes.

Paratropine $C_8H_{13}NO$. (202°). Formed from hydrotropine and K_3FeCy_6 (Ladenburg, *B*. 24, 1626).—$B'_2H_2PtCl_6$. [197°].—$B'HAuCl_4$. [182°].—$B'HCl6HgCl_2$. [225°]. V. sol. water.

ψ-Tropine $C_8H_{15}NO$. [108°]. (242°). Formed, together with tropic acid, by warming hyoscine with baryta-water (Ladenburg, *B*. 13, 1551; 17, 151; Liebermann, 24, 2587). Formed also by dissolving its benzoyl derivative in hot conc. HClAq (Hesse, *A*. 271, 210). Hygroscopic prisms (from chloroform), v. e. sol. water. Yields tropinic and ecgonic acids on oxidation.—$B'_2H_2SO_4$. Hygroscopic crystals.—$B'HAuCl_4$. [198°] (Ladenburg); [202°] (H.); [225°] (Liebermann).—$B'_2H_2PtCl_6$ 4aq. [206°, anhydrous]. Trimetric prisms; $a:b:c$ = ·702:1:·879.

Methylo-iodide $B'MeI$. [270°]. Rhombohedra. Yields $B'MeCl$ and $B'_2Me_2PtCl_6$. [216°] crystallising from water.

Benzoyl derivative $C_{15}H_{19}NO_2$. [48°]. Occurs in the leaves of Java coca (Liebermann, *B*. 24, 2336; Hesse, *A*. 271, 208). Colourless plates (from ether).—$B'HCl$. [270°].—$B'_2H_2PtCl_6$. Pale-yellow needles.—$B'MeI$.—$B'MeCl$.—$B'MeAuCl_4$.—$B'Me_2PtCl_6$ 2aq.

Mandelyl derivative $C_8H_{14}NO(CO.CH(OH).C_6H_5)$. *ψ-Homatropine.* Formed by heating ψ-tropine with mandelic anhydride at 200° (Liebermann a. Limpach, *B*. 25, 931).—$B'HCl$.—$B'_2H_2PtCl_6$.—$B'HAuCl_4$.

Tropyl derivative $C_8H_{14}NO(C_9H_9O_2)$. Isomeride of hyoscine. [88°]. $[\alpha]_D = -4.9°$. Nodules, insol. water, sol. alcohol.—$B'HCl$. [183°].—$B'_2H_2PtCl_6$.—$B'HAuCl_4$. [135°].

Atropyl derivative. [129°]. Formed from tropide and ψ-tropine at 200°. Crystals, sol. water. Split up by HClAq into atropic acid and ψ-tropine.

Oxy-tropine carboxylic acid

$\begin{array}{l}\underset{|}{C}H.\underset{|}{C}H_2.\underset{|}{C}H.CH(OH).CH(OH).CO_2H\\ CH.CH_2.NMe\end{array}$. *Dioxyanhydroecgonine.* Formed by oxidising hydroecgonine with $KMnO_4$ and aqueous Na_2CO_3 at 1° (Einhorn a. Rassoff, *B*. 25, 1395). Decomposes at 280°. V. e. sol. water and MeOH, insol. EtOH.—$B'HCl$. [251°].—$B'C\,H_3N_3O_7$.—KA'.

Methyl ether MeA'. [139°]. Tables, v. e. sol. $CHCl_3$. Yields $B'_2H_2PtCl_6$. [210°].

Benzoyl derivative of the methyl ether $C_5H_7MeN.CH(OH).CH(OBz).CO_2H$. [108°]. Needles.—$B'HNO_3$. [216°].—$B'HCl$. [203°].—$B'HAuCl_4$. [173°].—$B'_2H_2PtCl_6$. [208°].

Di-benzoyl derivative of the methyl ether $C_5H_7MeN.CH(OBz).CH(OBz).CO_2H$. Needles.—$B'HNO_3$. [190°].—$B'HCl$. [280°].—$B'_2H_2PtCl_6$. [205°].—$B'HAuCl_4$. [203°].

Reference.—Oxytropine.

TROPINE DIHYDRIDE $C_8H_{17}NO$ *i.e.*

$\begin{array}{l}\underset{|}{C}H_2.CH_2.\underset{|}{C}H.CH_2.CH_2OH\\ CH_2.CH_2.NMe\end{array}$. *Hydrotropine. Methyloxyethylpyridine hexahydride.* (233°). Formed from oxy-ethyl-piperidine and $KMeSO_4$ (Ladenburg, *B*. 24, 1622). V. sol. water and alcohol.—$B'HCl5HgCl_2$. [214°].—$B'HAuCl_4$. [170°]. Crystals.

TROPINIC ACID $C_8H_{13}NO_4$. [253°] (L.); [220°] (M.). A product of oxidation of tropine and of ecgonine by chromic acid mixture (Merling, *A*. 216, 348; Liebermann, *B*. 23, 2519). Needles, v. sol. water, sl. sol. alcohol, insol. benzene. Gives off CO_2 when heated. Forms salts with acids and bases.—BaA'_2. Very hygroscopic.—CaA'_2.—AgA'. Readily reduced.—$(HA')_2PtCl_4$.—$HA'HAuCl_4$. Golden prisms.—$HA'HCl$ aq.

TROPYLENE *v.* Tropilene.

TRUXENE $(C_9H_6)_x$. Formed by heating truxone with red P and HIAq (S.G. 1·7) at 180°

(Liebermann a. Bergami, *B.* 22, 786; 23, 317). Formed also by heating hydrindone with conc. HClAq, and by heating phenyl-propionic acid with P_2O_5 (Hausmann; Kipping, *C. J.* 65, 269). Needles or plates, melting above 360°, insol. $CHCl_3$. Oxidised by boiling HOAc and CrO_3 to crystalline 'tri-benzoylene-benzene,' which is not melted at 360°. HNO_3 forms (4,2,1)-nitro-phthalic acid.

(α)-TRUXILLIC ACID $C_{18}H_{16}O_4$ *i.e.*

$$\begin{array}{r}\text{CHPh.CH.CO}_2\text{H}\\ \text{CO}_2\text{H.CH---CHPh}\end{array}\ (?)$$

(γ)-*Isatropic acid.* [274°]. Formed, together with (β)-truxillic acid, by the action of boiling HClAq on isatropylcocaïne, which is a by-product in the preparation of cocaïne (Liebermann, *B.* 21, 2342; 22, 124, 783, 2242). Small needles (from alcohol), sol. hot HOAc. Yields cinnamic acid on distillation. Nitric acid (S.G. 1·52) forms two di-nitro- derivatives, [229°] and [290°]. Yields two isomeric sulphonic acids.—Na_2A'' 10aq (Drory, *B.* 22, 2256).—BaA″ $8\frac{1}{2}$aq. Crystalline, v. sol. water.—CaA″ aq.—Ag_2A''. Flocculent pp., sol. NH_3Aq.

Methyl ether Me_2A''. [174°]. (c. 300°).

Ethyl ether Et_2A''. [146°]. H.C.p. 2,720,900 (Liebermann, *B.* 25, 92). Yields $C_{18}H_{12}(NO_2)_2Et_2O_4$ [138°] (Homans, *B.* 24, 2590).

Isoamyl ether $(C_5H_{11})_2A''$. [83°]. Prisms. Ac_2O at 150° forms (α)-truxillic anhydride, while at 170° the product is (γ)-truxillic anhydride.

Di-amide $C_{18}H_{14}O_2(NH_2)_2$. [265°]. Needles, v. sl. sol. hot water, sl. sol. alcohol (Drory, *B.* 22, 2261).

Di-piperidide $C_{16}H_{14}(CO.NC_5H_{10})_2$. [259°]. Got from the chloride and piperidine (Herstein, *B.* 22, 2264). Crystalline powder, sol. alcohol.

Mono-piperidide $C_{16}H_{14}(CO_2H).CO.NC_5H_{10}$. [250°]. Yields MeA′ [151°] crystallising from ether in needles.

Anhydride $(C_{36}H_{30}O_7)_3$. [191°]. Mol. w. 1712 (1703 obs. by Raoult's method). Formed by heating the acid with Ac_2O and NaOAc at 100°. Needles (from benzene-ligroïn). Gives no fluorescein. When heated for an hour at 200° it changes to (γ)-truxillic anhydride.

(β)-Truxillic acid $C_{18}H_{16}O_4$ *i.e.*

$$\begin{array}{l}\text{CHPh.CH.CO}_2\text{H}\\ \text{CHPh.CH.CO}_2\text{H}\end{array}\ (?)$$

(δ)-*Isatropic acid.* [206°]. Formed at the same time as the (α)- acid (Liebermann, *B.* 21, 2342; 22, 783, 2243; 25, 90; 26, 837). More sol. water than the (α)- isomeride. Yields benzil on oxidation. Nitric acid (S.G. 1·52) forms a di-nitro- derivative [216°] (Homans, *B.* 24, 2590). Forms cinnamic acid on distillation.—Na_2A'' 2aq.—BaA″ 2aq. Sl. sol. water.—CaA″ 3 aq.—Ag_2A''.

Methyl ether Me_2A''. [76°]. Mol. w. 309 (by Raoult's method); calc. 324. H.C.p. 2,422,900. Monoclinic prisms; $a{:}b{:}c = \cdot826{:}1{:}2\cdot019$; $\beta = 89° 22'$.

Ethyl ether Et_2A''. [47°].

Chloride $C_{16}H_{14}O_2Cl_2$. [96°]. Tabular prisms, v. sol. ether (Drory, *B.* 22, 2260).

Monopiperidide $C_{16}H_{14}(CO_2H).CONC_5H_{10}$. [224°]. Formed from (β)-truxillic anhydride and piperidine (Herstein, *B.* 22, 2264). Needles, sl. sol. cold alcohol.

Dipiperidine $C_{16}H_{14}(CO.NC_5H_{10})_2$. [180°]. Formed from the chloride and piperidine. Prisms, v. sol. alcohol.

Phenylimide

$C_{16}H_{14}\begin{matrix}<\text{CO}\\ <\text{CO}\end{matrix}>NPh$. [180°]. Mol. w. 351 (obs.). Got by heating the anhydride with aniline. Colourless needles (from alcohol). Cold alcoholic potash forms the compound $CO_2H.C_{16}H_{14}.CO.NHPh$ [197°].

Phenyl hydrazide

$C_{16}H_{14}<\begin{matrix}\text{CO.NH}\\ \text{CO.NPh}\end{matrix}$ [218°]. Formed from the acid, phenyl-hydrazine, and HOAc on warming. Crystals (from HOAc).

Fluorescein

$C_{16}H_{14}<\begin{matrix}\text{C}(C_6H_3(OH)_2)_2\\ \text{CO}\end{matrix}>O$. Formed by heating the acid or its anhydride with resorcin at 240°. Amorphous brownish-red powder, sol. alkalis forming fluorescent solutions, v. sol. alcohol, insol. benzene.

Anhydride $C_{18}H_{14}O_3$. [116°]. Mol. w. 278 calc., 289 obs. by Raoult's method. Does not change to an isomeride when heated.

(γ)-Truxillic acid $C_{18}H_{16}O_4$. ε-*Isatropic acid.* [228°]. Formed by heating the anhydride of the (α)-isomeride with HCl at 160°. Needles (from dilute alcohol), v. sl. sol. hot water, v. sol. ether. Yields cinnamic acid on distillation. Gives the same anhydride as the (α)- isomeride (Ladenburg, *B.* 22, 124). Heated with HClAq at 260° it is changed to (α)-truxillic acid. HNO_3 (S.G. 1·52) forms a di-nitro- derivative [293°].

Salts.—BaA″ 11aq.—CaA″ $3\frac{1}{2}$aq.—CaA″ $6\frac{1}{2}$aq.—Ag_2A'': crystalline pp.

Methyl ether Me_2A''. [126°]. Needles. Mol. w. 332 (calc. 324).

Mono-ethyl ether $C_{16}H_{14}(CO_2H).CO_2Et$. [172°]. Formed, together with the di-ethyl ether, by saturating an alcoholic solution of the acid with HCl (Liebermann, *B.* 22, 2240). Needles, yielding AgA′. At 320° it is converted into a mixture of (α)-truxillic acid and (α)-truxillic ether.

Di-ethyl ether Et_2A''. [98°]. Needles, v. sol. alcohol (Drory, *B.* 22, 2260).

Mono-piperidide $C_{16}H_{14}(CO.NC_5H_{10}).CO_2H$. [261°]. Plates (from water or dilute alcohol). Yields MeA′ [201°] and a piperidine salt $(C_5H_{11}N)HA'$ 3aq [218°], which crystallises (with 3aq) from alcohol (Herstein, *B.* 22, 2262).

Di-piperidide $C_{16}H_{14}(CO.NC_5H_{10})$. [248°]. Needles, insol. water, sol. alcohol.

Mono-anilide $C_{16}H_{14}(CO.NHPh).CO_2H$. [220°]. Formed by heating the acid with aniline (Liebermann, *B.* 26, 838). Needles (from dilute alcohol).

Aniline $C_{16}H_{14}(CO.NHPh)_2$. [255°].

Anhydride $C_{16}H_{14}O_3$. Mol. w. 282 (calc. 278). Gives no fluorescein.

(δ)-Truxillic acid $C_{18}H_{16}O_4$. [174°]. Formed by fusing (β)-truxillic acid with potash. Needles (from water), v. sol. alcohol (Liebermann, *B.* 22, 2250; Hesse, *A.* 271, 205). Yields a di-nitro-derivative [226°]. Yields cinnamic acid on distillation.—CaA″: rosettes of needles.—BaA″ 4aq: prisms, sl. sol. Aq.—CuA″ 2aq.—Ag_2A''.

Methyl ether Me_2A''. [77°]. Needles.

Reference.—OXY-TRUXILLIC ACID.

TRUXONE $(C_9H_6O)_x$, $x = 2$ or 3. [289°]. Formed from (α)-truxillic acid and fuming H_2SO_4 (S.G. 1·96) at 15° (Liebermann a. Bergami, *B.* 22, 784; 23, 320). Plates (by sublimation), insol. water, acids, and bases. Not attacked by HNO_3. Yields $(C_9H_6Cl_2)_3$ [178°]. Aniline and HOAc on

boiling form the anilide $(C_8H_6{:}NPh)_x$ **crystallising in needles, [270°], decomposed by fusion.**

Phenyl-hydrazide $(C_8H_6{:}N_2HPh)_x$. [c. 270°]. Needles, v. sl. sol. alcohol.

Oxim $(C_8H_6{:}NOH)_x$. Very unstable, easily changing to an anhydride. Boiling Ac_2O yields $(B_8H_6{:}NOAc)_x$ [261°], m. sol. HOAc.

TULUCUNIN $C_{20}H_{14}O_4$. Occurs in the bark of *Tarapa Tulucuna* (Caventou, *J. Ph.* [3] 35, 189). Light-yellow amorphous resin, with very bitter taste, sl. sol. water, v. sol. alcohol, insol. ether. Turned blue by cold H_2SO_4.

TUNGSTATES, *and derivatives of*; *v.* TUNGSTEN OXYACIDS, SALTS, AND DERIVATIVES OF, p. 802; also TUNGSTEN THIO-ACIDS, AND SALTS OF, p. 810.

TUNGSTEN. W. (*Wolfram.*) At. w. 183·6. Mol. w. is unknown. S.G. 18·77 (Waddell, *Am.* 8, 280); 18·77 (Moissan, *C. R.* 116, 1225); 19·13 at 4° (Roscoe, *C. J.* [2] 10, 286); for other determinations *v.* Bernoulli (*P.* 111, 576), Zettnow (*P.* 111, 16). S.H. (6° to 15°) ·035 (De la Rive a. Marcet, *A. Ch.* [2] 75, 113). S.V.S. c. 9·7.

Historical.—In 1785 a new acid was prepared by J. and F. d'Elhujar from the mineral *wolframite*, and shown to be identical with an acid obtained three years before from *tungstein* by Scheele (*Opusc.* 2, 119). The metal of the new acid was isolated by J. and F. d'E. For many years the new metal was known as *wolfram* or *tungsten* (from Swedish = heavy stone); the latter name has gradually driven out the former in England and France, but the metal is generally called wolfram in Germany; the symbol W is universally employed.

Occurrence.—Never uncombined. *Wolframite* (tungstate of Fe and Mn) is found in considerable quantities in Cornwall, Saxony, Bohemia, &c.; *tungstenite*, or *scheelite* (tungstate of Ca), *scheeletine* (tungstate of Pb), and some other tungstates occur in various localities; *wolframine* or *wolfram-ochre*, WO_3, is also found. Some tin ores contain compounds of W, and W is therefore not infrequently found in specimens of tin.

Formation.—1. By reducing WO_3 by heating to redness in H (Berzelius, *P.* 4, 147; Wöhler, *A.* 77, 262; Zettnow, *P* 111, 16; Roscoe, *C. N.* 25, 61, 78).—2. By heating WO_3 with Na and NaCl (Z., *l.c.*).—3. By reducing WO_3 by mixing with 10 p.c. charcoal and 2 p.c. resin, and heating in a closed crucible for some hours to a white heat (Filsinger, *S. C. I.* 1878. 229).—4. By passing vapour of oxychloride of W and H through a red-hot tube (von Uslar, *A.* 94, 255). 5. By heating WCl_5 in H, in a zinc bath (Roscoe, *l.c.*).—6. By strongly heating the salt $(NH_4)_2WO_4$ in a carbon crucible (Bucholz, *P.* 111, 576).—7. By strongly heating the nitride (*q. v.*, p. 800) in H (Wöhler, *A.* 73, 190).

Preparation.—1. Pure WO_3 is heated to bright redness, in a Pt tube, in a stream of pure dry H (*v. Formation*, No. 1).—2. A mixture of pure WO_3 and dry lampblack is heated in an electric furnace (Moissan, *C. R.* 116, 1225).

WO_3 is prepared from *wolframite* by heating the very finely powdered mineral with conc. HClAq, pouring off the solution from time to time and adding more HClAq, and after some time adding a little HNO_3Aq until most of the brown solid is changed to yellow $WO_3.xH_2O$, washing the residue thoroughly by decantation, adding a considerable quantity of NH_3Aq and warming, filtering from quartz, unchanged *wolframite*, &c., evaporating the solution until small lustrous crystals of an acid ammonium tungstate separate, boiling these crystals for a long time with HNO_3Aq, washing, and heating the residue (Scheibler, *J. pr.* 83, 239; *cf.* Bernoulli, *P.* 111, 590).

Properties.—A steel-grey, hard, brittle, crystalline powder (Riche, *A. Ch.* [3] 50, 5). By reducing the nitride in H, Wöhler (*A.* 73, 190) obtained W as a black powder. By reducing WO_3 by C in an electric furnace, Moissan (*C. R.* 116, 1228) obtained a lustrous, very hard, greyish white solid. As produced by passing the vapour of WO_2Cl_2 mixed with H through a red-hot tube, W forms a shining, dark steel-grey, mirror-like deposit, which can be detached from the tube in hard, brittle crusts (von Uslar, *A.* 94, 255). W can be melted in the O-H flame, part of it burning to WO_3 (Riche, *l.c.*); or by using a current from 600 Bunsen cells, in an atmosphere of N (Desprez, *C. R.* 29, 549). Considerable masses may be melted by employing the current from a dynamo (*v.* Huntington, *C. N.* 46, 163). W was regarded by Faraday as diamagnetic (*T.* 1846. 49). The emission spectrum is described by Thalén (*A. Ch.* [4] 18, 202). W is unchanged in air, but when the pulverulent metal is heated it burns to WO_3; compact W burns in air only at very high temperatures; as obtained by reducing WCl_6 by H, W is said to be pyrophoric. Water is decomposed by W at a red heat. The metal is scarcely acted on by HClAq or H_2SO_4Aq; it is oxidised by HNO_3Aq to $WO_3.xH_2O$; the pulverulent metal dissolves slowly in caustic alkali solutions. Finely divided W reduces and ppts. many metals from solutions of their salts. W combines directly with Br, Cl, I, or S. W is not acted on by heating in NH_3 nor in CO (*v.* Rideal, *C. J.* 55, 45; Smith a. Oberholtzer, *Zeit. f. anorg. Chemie*, 5, 63).

The at. w. of W has been determined (1) by reducing WO_3 in H, and again oxidising W to WO_3 (Berzelius, *P.* 4, 151 [1825]; Schneider, *J. pr.* 50, 158, 161 [1850]; Marchand, *A.* 77, 263 [1850]; von Borch, *J. pr.* 54, 254 [1851]; Riche, *A. Ch.* [3] 50, 10 [1856]; Dumas, *A. Ch.* [3] 55, 143 [1859]; Bernoulli, *P.* 111, 597 [1860]; Persoz, *A. Ch.* [4] 1, 93 [1864]; Roscoe, *C. N.* 25, 61, 73 [1872]; Waddell, *Am.* 8, 280 [1887]); (2) by determining H_2O in $BaW_4O_{13}.9H_2O$ (Scheibler, *J. pr.* 83, 324 [1861]); (3) by reducing WO_3 in H and determining H_2O produced (Bernoulli, *P.* 111, 597 [1860]); (4) by analysing Ag_2WO_4, and $FeWO_4$ (Zettnow, *P.* 130, 16, 240 [1867]); (5) by analysing WCl_6 (Roscoe, *C. N.* 25, 61, 73 [1872]); (6) by determining S.H. of W (De la Rive a. Marcet, *A. Ch.* [2] 75, 113 [1840]); (7) by determining V.D. of WCl_5, WCl_6 and $WOCl_4$ (*v.* these compounds). The older determinations gave values for at. w. varying from 186 to 189; the most recent determination (by Waddell) gave 184·04; Roscoe's determinations, made by reducing WO_3 to W and oxidising W again to WO_3, by finding the ratio of WCl_6 to AgCl and to Ag, and by reducing WCl_6 in H, gave values varying from 183·25 to 183·77. The number 183·6 is probably correct to half a unit. The atom of W is pentavalent in the gaseous molecule WCl_5, and hexavalent in the gaseous molecule WCl_6.

W is the fourth member (the third is as yet unknown) of the even series, or chromium, family of Group VI. in the periodic arrangement of the elements. W is followed in its family by U, and it succeeds Mo and Cr. W very closely resembles Mo; like that element W is both metallic and non-metallic; the balance of these properties being, however, not quite so evenly maintained in W as in Mo. It is doubtful whether any definite salt has been isolated derived from an oxyacid by replacing H by W. The oxide WO_3 acts as a fairly acidic oxide; like MoO_3 it is remarkable for the large number of compounds it forms, simultaneously, with oxides that are more basic and oxides that are less basic than itself. The chemical relations of W are discussed in the article CHROMIUM GROUP OF ELEMENTS, vol. ii. p. 168.

Reactions.—1. Heated in *air* burns to WO_3; finely divided W burns easily; compact W only at a very high temperature (*v.* Roscoe, *C. N.* 25, 61, 73).—2. Heated to redness in *steam* gives H and oxide (? WO_3).—3. Reacts with hot *nitric acid*, or *aqua regia*, to form $WO_3.xH_2O$; the same product is obtained by heating W with conc. *sulphuric* or *hydrochloric acid*, but oxides intermediate between WO_2 and WO_3 are formed at first (Riche, *A. Ch.* [3] 50, 15).—4. Pulverulent W dissolves in boiling conc. *potash solution*, giving H and a tungstate of K (Riche, *l.c.*). 5. Heated in *carbonyl chloride* to 150°-200° $WOCl_4$ is produced, mixed with C (Smith a. Oberholtzer, *Zeit. f. anorg. Chemie*, 5, 63).—6. By heating to redness with *sulphur chloride* a red, crystalline thiochloride, probably $W_2S_7Cl_8$, is formed as a sublimate, unstable in air (S. a. O., *l.c.*).—7. Finely divided W reduces solutions of several *metallic* salts; $AgNO_3$ and $AuCl_3$ solutions are reduced to Ag and Au, $HgCl_2$ to HgCl, Cu, Pd, Pt and Rh are partially ppd. from solutions; Bi, Cd, and Pb are not ppd. (Smith, *Zeit. f. anorg. Chemie*, 1, 360).

Combinations.—1. Heated in *oxygen*, WO_3 is formed.—2. Combines with *chlorine*, to form WCl_6, at c. 300°; with *bromine*, to form WBr_5, at a higher temperature; and with *iodine*, to form WI_2, when strongly heated.—3. Heated with *sulphur*, forms WS_2.—4. The compound W_3P_4 is said to be formed by strongly heating W in *phosphorus* vapour (Wöhler a. Wright, *A.* 79, 244).

Detection and Estimation.—Compounds of W form colourless beads with borax or microcosmic salt in the outer blowpipe flame. The borax bead is yellow in the inner flame if a considerable quantity of a compound of W is present. The microcosmic salt bead is blue in the inner flame in the absence of compounds that themselves form coloured beads; in presence of iron compounds the bead is blood-red, but addition of tin causes it to become blue. Soluble alkali tungstates are formed by fusion with alkali carbonate or nitrate; addition of excess of H_2SO_4Aq, HClAq, H_3PO_4Aq, $H_2C_2O_4Aq$, or $HC_2H_3O_2Aq$ to an aqueous solution of a tungstate, followed by immersion of a piece of zinc in the liquid, produces a blue colour; addition of H_2S to an acidulated solution of a tungstate gives no pp., but a blue colour. According to Mallet (*C. J.* 28, 1228), the successive addition of small pieces of zinc to the solution obtained by adding excess of conc. HClAq to an alkaline tungstate produces various colours, the most marked of which is a brilliant magenta-red. By adding KCNSAq and then small pieces of zinc to a solution of an alkaline tungstate in excess of conc. HClAq, a deep green colour is produced; and an amethyst colour is noticed when KCNSAq is added to the solution of an alkaline tungstate, the solution is then diluted, HClAq is then added, and lastly zinc is placed in the liquid. Very minute quantities of W can be detected by adding SO_2Aq and Zn to solution of an alkaline tungstate, whereby a light-blue colour is obtained (M., *l.c.*, p. 1233). W is estimated as WO_3, obtained by evaporation and strongly heating; for separation from other elements a *Manual of Analysis* must be consulted.

Tungsten, alloys of. By reducing mixtures of WO_3 with oxides of Sb, Bi, Co, Cu, Pb, Ni, or Zn, Bernoulli (*P.* 111, 573) obtained alloys of W with these metals, provided there was not more than 10 p.c. of the foreign metal present. An alloy with *aluminium*, approximately WAl_4, was obtained by Wöhler a. Michel (*A.* 115, 102) by heating a mixture of WO_3, Al, cryolite, and NaCl and KCl. W alloys with *iron*; *v.* Poleck a. Grützer (*B.* 26, 35) for an alloy approximately W_2Fe. An alloy of 9 or 10 p.c. W with steel is extremely hard (*v.* Bernoulli, *l.c.*; Philipp, *Hofmann's Ber. über chem. Industrien*, 745; Le Guen, *C. R.* 56, 593; 59, 786; 63, 967; 64, 619; 68, 592; Caron, *A. Ch.* [3] 68, 143; Osmond, *C. R.* 104, 985; Gruner, *C. R.* 96, 197).

Tungsten, amidonitrides of, *v.* TUNGSTEN NITRIDES, AND ALLIED COMPOUNDS, p. 799.

Tungsten, bromides of. The elements combine when heated together to form WBr_5, and by partial reduction in H this gives WBr_2.

TUNGSTEN PENTABROMIDE WBr_5. The formula is probably molecular, from the analogy of WCl_5. Prepared by heating W in excess of Br vapour, taking care that every trace of water and O are excluded. Dark, violet-brown needles, resembling I; melts at 276° and boils at 333°, giving off a dark-brown vapour; decomposed on distillation, with separation of Br; moist air or water forms HBrAq and blue oxide of W; heated to 350° in a stream of H, WBr_2 is formed (Roscoe, *C. N.* 25, 73; *cf.* Borck, *J. pr.* 54, 254; Blomstrand, *J. pr.* 82, 408).

TUNGSTEN DIBROMIDE WBr_2. Obtained, as a bluish-black, velvety solid, when WBr_5 is heated at c. 350° (in a bath of $ZnCl_2$) in a stream of dry H; WBr_5, $WOBr_4$, and Br distil over, and WBr_2 remains. Heated above c. 400° in H gives W and HBr; with HNO_3Aq gives WO_3, HBrAq, and NH_4NO_3Aq (Roscoe, *l.c.*).

Tungsten, chlorides of. When W is heated in Cl the compound WCl_6 is formed, and by reduction in H or CO_2 this gives WCl_5, WCl_4, and WCl_2. Great confusion existed about the compositions of the chlorides of W until Roscoe's researches in 1872 established the formulæ.

TUNGSTEN HEXACHLORIDE WCl_6. Mol. w. 395·82. Prepared by heating W in Cl (Roscoe, *C. N.* 25, 61). The materials must be perfectly dry, and every trace of air must be excluded, else $WOCl_4$ is formed; the WCl_6 sublimes on the cooler part of the tube, and is then distilled several times in a stream of *dry* Cl, and then in a current of *dry* H (a small quantity of WCl_5 is formed, and distils off with the H). Teclu (*A.* 187, 255) obtained WCl_6 by heating WO_3 and PCl_5 in a sealed tube at 170°. WCl_6 forms dark-violet crystals; crystallises from CS_2 in brown, six-sided tablets, from $POCl_3$ in steel-blue, metal-like, regular crystals (T., *l.c.*). Melts, out of contact with air, at 275°, and boils at 346·7° at 760 mm. pressure (R., *l.c.*). V.D. 190 at 350° (Debray, *C. R.* 60, 820; Roscoe, *l.c.*); V.D. 168·8 at 440° (D., *l.c.*; R., *l.c.*; Rieht, *B.* 3, 666). Dissolves readily in CS_2, or $POCl_3$ (T., *l.c.*). Distilled in CO_2 gives WCl_5 and Cl; this fact taken in connection with V.D. at 440° shows that at somewhat above b.p. WCl_6 probably dissociates to WCl_5 and Cl. WCl_6 is unchanged in air; but if a trace of $WOCl_4$ is present, HClAq and WO_3 are formed. Hot water produces WO_3 and HClAq. Heated in air, or in O, forms $WOCl_4$ (Roscoe, *l.c.*; Blomstrand, *J. pr.* 82, 417). $WOCl_4$ is also formed by heating WO_3 with WCl_6. WCl_6 interacts with NH_3, at the ordinary temperature, to form NH_4Cl and W_2N_3 (Rideal, *C. J.* 55, 44).

TUNGSTEN PENTACHLORIDE WCl_5. Mol. w. 360·45. Prepared by repeatedly heating WCl_6 somewhat above its b.p. (346·7°) in a stream of dry H, and when a solid residue has been formed removing the WCl_5 from less volatile lower chlorides by heating in CO_2 (Roscoe, *C. N.* 25, 61). Black, lustrous, needle-shaped crystals; very deliquescent; melts at 248°, and boils at 275·6° (R., *l.c.*). V.D. 175·6 to 179·9 at 350°; 185·7 to 186·4 at 440° (R., *l.c.*). Slightly soluble in CS_2 forming a blue liquid; forms an olive-green solution in water, but is mostly decomposed to HClAq and blue oxide of W. Heated in O forms $WOCl_4$ and Cl (R., *l.c.*; *cf.* Blomstrand, *J. pr.* 82, 425; 89, 230).

TUNGSTEN TETRACHLORIDE WCl_4. This compound is present in the solid residue obtained by heating WCl_6 in H in the preparation of WCl_5 (*v. supra*); it is prepared by distilling this residue, in a bath of H_2SO_4, in a stream of dry CO_2, returning the distillate to the distilling vessel and heating again, and repeating these processes several times (Roscoe, *l.c.*). A soft, crystalline, greyish-brown powder; very hygroscopic; has not been fused or volatilised; heated strongly, it gives WCl_5 and WCl_2. Heated in H to c. 440° pyrophoric W is produced. Decomposed by water to WO_2 and a greenish-brown solution (R., *l.c.*).

TUNGSTEN DICHLORIDE WCl_2. Prepared by heating WCl_4, in a bath of zinc, in a stream of dry CO_2; WCl_5 distils off and WCl_2 remains. A loose, grey, amorphous powder; water forms WO_2 and HClAq, with evolution of H; interacts with H which has been passed through HNO_3Aq to form WO_3, HCl, and NH_4NO_3 (R., *l.c.*).

Tungsten, cyanides of. No cyanides of W have been isolated; according to Wyrouboff (*A. Ch.* [5] 8, 444; *cf.* Atterberg, *Bl.* [2] 24, 355), compounds containing W, K, and $FeCy_6$ are obtained by adding HClAq to a mixture of K tungstates and K ferrocyanide.

Tungsten, fluorides of. No fluoride of W has been isolated. According to Berzelius (*P.* 4, 147), when a solution of $WO_3.H_2O$ in HFAq is evaporated and the residue is treated with water, a solid remains which is free from F after being heated in NH_3. According to Riche (*A. Ch.* [3] 50, 41), a solution of tungstic hydroxide in HFAq gives crystals of $WO_3.H_2O$ on evaporation.

Tungstoxyfluorides. (*Fluotungstates.*) By dissolving tungstates of the form M_2WO_4 in HFAq, Marignac obtained a series of compounds of the forms $2M^IF.WO_2F_2.xH_2O$ and $M^{II}F_2.WO_2F_2.xH_2O$, and also a few compounds of the form $M^IF.WO_2F_2.H_2O$ (*A. Ch.* [3] 69, 67). These compounds may be regarded as salts of the hypothetical acids $H_2WO_2F_4$ and HWO_2F_3; they are similar to some classes of the compounds described as *fluomolybdates* (this vol. p. 425).

The *tungstoxyfluorides* etch glass even when dry; they react slowly with acids, giving $WO_3.H_2O$. The salts of the forms $M^I_2WO_2F_4$ and $M^{II}WO_2F_4$ were prepared by dissolving $M^I_2WO_4$ and $M^{II}WO_4$ in HFAq and evaporating; in some cases also by dissolving $WO_3.H_2O$ in HFAq, adding MOH, and evaporating. The salts of the form $M^IWO_2F_3$ were formed by dissolving acid tungstates in HFAq and evaporating. The following compounds were isolated: (1) $M^I_2WO_2F_4.xH_2O$; $M = NH_4$, $x = 0$; $M = K$, $x = 1$; $M = Na$, $x = 0$; (2) $M^{II}WO_2F_4.xH_2O$; $M = Zn$, $x = 10$; (3) $MWO_2F_3.xH_2O$; $M = NH_4$, $x = 1$; $M = K$, $x = 1$. The salts $(NH_4)_4WO_2F_6.(NH_4)_2WO_4$ and $CuWO_2F_4.NH_3$ were also obtained.

By dissolving $K_2WO_2F_4.H_2O$ in 4 p.c. H_2O_2Aq, and crystallising from dilute H_2O_2Aq containing a little HF, Piccini (*Zeit. f. anorg. Chemie*, 2, 21) obtained $K_2WO_3F_4.H_2O$. P. calls this compound *fluoroxypertungstate*; it might also be named *pertungstoxyfluoride*.

Tungsten, haloid compounds of. When W is heated in a stream of Cl the compound WCl_6 is formed, and this by reduction in H gives WCl_5, WCl_4, and WCl_2. The compound WBr_5 is formed by heating W in Br vapour, and WBr_2 is obtained by partially reducing WCl_5 in H. Small quantities of WI_2 are obtained by heating W in vapour of I. No fluoride of W has been isolated. Oxychlorides and oxybromides of the forms WOX_4 and WO_2X_2 are obtained by heating W oxides in Cl or Br, and in other ways. The following compounds have been vaporised, and the simplest formulæ are molecular: WCl_6, WCl_5, $WOCl_4$. The formulæ WBr_5, $WOBr_4$, WO_2Cl_2, and WO_2Br_2 are probably molecular; but if the analogy of the chlorides and bromides of Mo of the form Mo_xX_{2x} is to be followed (*v.* vol. iii. pp. 427, 428) it is probable that the molecular formulæ of the dichloride and dibromide of W are not less than W_3X_6.

Tungsten, hydroxides of, *v.* TUNGSTEN OXIDES AND HYDRATED OXIDES (p. 800), also TUNGSTEN OXYACIDS (p. 802).

Tungsten, iodide of, WI_2. This, the only iodide of W that has been isolated, is obtained, in very small quantities, by passing I vapour, mixed with CO_2, over red-hot W. It forms a metal-like, greenish crust; heated in air it gives off I and leaves WO_3; it is not decomposed by water (Roscoe, *C. N.* 25, 73).

Tungsten, nitrides of; *and allied compounds.* Compounds of W with N, and probably also with N and H, are formed by heating WCl_6 or $WOCl_4$ in NH_3; the interaction of NH_3 and

WO_3 probably produces a compound, or compounds, of W, N, H, and O; and a compound of W, N, and O is perhaps formed by heating WO_3 with NH_4Cl.

TUNGSTEN NITRIDES. By passing dry NH_3 over WCl_6, and washing away the NH_4Cl produced, by water, Rideal (*C. J.* 55, 44) obtained a black lustrous powder, agreeing fairly with the composition W_2N_3. This substance is insoluble in HNO_3Aq, dilute H_2SO_4Aq, or NaOHAq; hot conc. H_2SO_4 produces NH_3 and WO_3; fusion with NaOH forms Na tungstate; heating in air, or with *aqua regia*, oxidises it to WO_3 (*R.*, *l.c.*).

By continued heating WCl_6 in NH_3, to a temperature difficult to regulate, as slightly too high a temperature produces W, Uhrlaub obtained a black substance to which he gave the formula W_3N_2 (*Die Verbindungen einiger Metalle mit Stickstoff*, Göttingen, 1859).

TUNGSTEN AMIDONITRIDES. By the action of NH_3 on WCl_6, Wöhler (*A.* 73, 198) obtained a black substance containing from 86·76 to 90·8 p.c. W, and 8·24 p.c. N; W. supposed this substance to be a mixture of two amidonitrides, $2WN_2.W(NH_2)_2$ and $2WN.W(NH_2)_2$. W. obtained similar black substances, which he did not analyse, by heating chlorides of W with NH_4Cl (*A.* 105, 258).

Compounds of tungsten with N, H, and O. Wöhler (*A.* 73, 198) obtained a black substance by heating WO_3 to dull redness in dry NH_3; the percentage of W in this substance varied from 87·65 to 88·47, and it contained 7·15 p.c. N, and c. ·2 p.c. H. To this substance W. gave the formula $W_8N_{10}H_4O_4$ ($=4WN_2.W_2(NH_2)_2.2WO_2$). Rideal (*C. J.* 55, 44) passed dry NH_3 over WO_3 heated to a dull redness until the yellow WO_3 was changed to a black, amorphous powder; he allowed to cool, and removed excess of NH_3 by passing a current of dry air through the tube. The black substance thus obtained contained 85·26 p.c. W, and 7·4 p.c. N; assuming c. ·3 p.c. H, the numbers agreed fairly with the formula $W_5N_6H_3O_5$.

Compound of tungsten with N and O. Rideal (*l.c.*) obtained a black powder, agreeing in composition approximately with the formula $WN_2.WO_3$, by heating WO_3 with NH_4Cl until the weight became constant. According to Rideal (*l.c.*) finely divided W does not change when heated in a stream of dry NH_3, after having been heated to redness in dry H; nor does NH_3 react with the blue oxide of W when heated therewith.

Tungsten, oxides and hydrated oxides of. When powdered W is heated in O it combines to form WO_3; by heating this oxide in H a blue oxide is formed, to which various formulæ intermediate between WO_3 and WO_2 have been assigned; by further heating in H, or with C, the dioxide WO_2 is produced. There are indications of an oxide with more O than WO_3. WO_2 dissolves in acids, but corresponding salts have not been isolated; the blue oxide separates from these solutions; WO_2 is also soluble in alkali solutions. WO_3 is insoluble in acids; it dissolves in alkali and alkaline carbonate solutions, forming tungstates (*v.* under TUNGSTEN OXYACIDS, p. 802). WO_3 combines with many acidic oxides to form compounds which react as acids (*v.* p. 801). WO_3 is the anhydride of more than one tungstic acid (*v.* p. 801). None of the oxides has been vaporised; the mol. w. of none is known.

TUNGSTEN DIOXIDE WO_2. (*Brown oxide of tungsten.*)

Formation.—1. By heating a mixture of WO_3 and C to redness (Buchholz, *S.* 3, 1).—2. By heating WO_3 to incipient redness in H (Wöhler, *A.* 73, 198; 77, 262).—3. By decomposing WCl_4, or WCl_2, by H_2O (Roscoe, *C. N.* 25, 61, 73).—4. By the reaction of Zn and HClAq on WO_3 (Wöhler, *P.* 2, 345), or on solution of a metatungstate (Riche, *l.c.*).

Preparation.—WO_3 is placed in a porcelain tube closed at one end and provided with a long opening in the middle; this tube is placed inside another porcelain tube which is kept at red heat, while H is passed through as long as water continues to be formed (Wöhler, *A.* 77, 262 *note*); the product is allowed to cool in H, and is kept in H for 24 hours (Riche, *A. Ch.* [3] 50, 29).

Properties.—A brown powder with a slight violet sheen; prepared by reducing WO_3 by Zn and HClAq, the oxide is obtained in metal-like lustrous crystals, pseudomorphs of WO_3. S.G. 12·11 (Karsten, *S.* 65, 394).

Reactions.—1. Moist WO_2 oxidises rapidly in *air* to WO_3; as prepared by reducing WO_3 in H it is pyrophoric, but if allowed to cool slowly in H the product is not pyrophoric (Berzelius, *P.* 4, 147; 8, 267; Wöhler, *l.c.*; Riche, *l.c.*).—2. Heated strongly in *hydrogen* gives W.—3. *Chlorine* forms WO_2Cl_2 when heated with WO_2 (Roscoe, *l.c.*, p. 63).—4. Heated to dull redness in a stream of *ammonia*, a compound, or compounds, of W with N, H, and O is formed (*v.* Compounds of W with N, H, and O, under TUNGSTEN NITRIDES, *supra*).—5. By heating with *sal ammoniac*, Rideal (*C. J.* 55, 44) obtained a black powder approximately $WN_2.WO_3$ (*v. Compound of W with N and O, supra*).—6. Moist WO_2 dissolves easily in warm *hydrochloric* or *sulphuric acid*, forming reddish-brown solutions from which blue oxide of W separates. WO_2 prepared in the dry way is scarcely acted on by acids, except *aqua regia*, which oxidises it to WO_3.—7. WO_2 dissolves in conc. *potash solution*, giving off H, and forming K tungstate. 8. Reduces *mercuric chloride* to HgCl, and ppts. Cu_2O from solutions of *copper salts* (Riche, *A. Ch.* [3] 50, 5).—9. Heated in *nitric oxide* to below 500° gives the blue oxide; oxidised to WO_3 by heating in *nitrogen dioxide* to c. 300° (Sabatier a. Senderens, *C. R.* 114, 1429; 115, 236).

BLUE OXIDE OF TUNGSTEN. Blue compounds of W and O are obtained by heating WO_3 with reducing agents; analyses lead to formulæ such as W_2O_5, W_3O_8, or W_4O_{11}, intermediate between WO_2 and WO_3. Malaguti (*A. Ch.* [2] 60, 273) gave the formula W_2O_5 to the blue product of heating WO_3 in H to c. 250°; von Uslar (*Beiträge zur Kenntniss des W und Mo* [Göttingen, 1855]) gave the formula W_3O_8. Gmelin said that a blue oxide of the composition W_4O_{11} is formed by strongly heating WO_3 in CO.

Blue compounds are also obtained by strongly heating NH_4 tungstates out of contact with air (Malaguti, *l.c.*; von Uslar, *l.c.*). Aqueous solutions of WO_3 or tungstates are coloured blue by the action of very weak reducers, *e.g.* by exposing moist WO_3 on paper to sunlight (Liesegang, *C. C.* 1865. 943), or by the action of $SnCl_2$Aq on tungstates (Bunsen, *A.* 138, 289; *v.* also Scheibler, *J. pr.* 83, 313). Conc. H_2SO_4 or HClAq gives a blue colour when heated with W (Riche, *A. Ch.* [3] 50, 15). Tungstates boiled with acetic acid and then electrolysed give blue coloured substances (Smith, *B.* 13, 753).

Peroxides of tungsten. Fairley (*C. J.* 31, 141) obtained indications of an oxide with more O than WO_3, by dissolving $WO_3.2H_2O$ in H_2O_2Aq, and evaporating over H_2SO_4 *in vacuo*; the green, transparent, yellow scales thus obtained dissolved in water, forming a solution which could be titrated with $KMnO_4$Aq, with separation of $WO_3.xH_2O$. Cammerer (*Chem. Zeitung*, 15, 957) found that WO_3 dissolved in boiling H_2O_2Aq, with evolution of O; on spontaneous evaporation he obtained a yellow powder, to which he gave the formula $WO_3.H_2O_2.H_2O$ (*cf.* reaction of H_2O_2Aq with CrO_3Aq, vol. ii. p. 166). According to Péchard (*C. R.* 112, 1060), a salt $Na_2O.W_2O_7.2H_2O$ is formed by boiling Na paratungstate solution with H_2O_2Aq and evaporating *in vacuo*.

Tungsten trioxide WO_3. (*Tungstic anhydride.* Sometimes erroneously called *tungstic acid.*)

Occurrence.—As *tungstic ochre* or *wolframine* in Cumberland, Connecticut, North Carolina, &c.

Formation.—1. By strongly heating in air tungstate of NH_4 or of Hg^I.—2. By strongly heating $WO_3.xH_2O$.—3. By burning W in air or O.

Preparation.—An aqueous solution of commercial Na_2WO_4 is poured into boiling HClAq (1:1); the ppd. WO_3 is washed with HClAq until NaCl is completely removed; it is then washed with water to remove all HCl, and dissolved in NH_3Aq; the solution is evaporated to dryness, and the NH_4 salt thus obtained is heated in an open crucible until every trace of NH_3 is driven off (Roscoe, *C.N.* 25, 73). Bernoulli (*P.* 111, 590) recommends to boil the NH_4 salt for a long time with successive quantities of HNO_3Aq (to remove traces of Na salts), and to wash the residual WO_3 quite free from acids (*cf.* Zettnow, *P.* 130, 16, 240). WO_3 is obtained in crystals by very strongly heating the amorphous oxide (Bernoulli, *P.* 111, 595; Schafarik, *W. A. B.* 47, 246); by dissolving WO_3 in molten borax (Nordenskjold, *P.* 114, 612); by strongly heating the oxide in a current of HCl (Debray, *C. R.* 55, 287); or by heating to whiteness a mixture of Na_2WO_4 and Na_2CO_3 imbedded in NaCl, when crystals of WO_3 sublime (D., *l.c.*).

Na_2WO_4 may be prepared from *wolframite* by heating a mixture of 150 pts. of the finely powdered mineral with 100 pts. calcined Na_2CO_3 and 15 pts. $NaNO_3$, for four or five hours, in an iron vessel, lixiviating with water and crystallising (*v.* Franze, *J. pr.* [2] 4, 238; *cf.* Huntington, *B.* 17, 203; Scheibler, *J. pr.* 83, 239).

Waddell (*Am.* 8, 380) prepares pure WO_3 from *tungstenite*, by treating the powdered mineral with *aqua regia*, washing the residue, fusing it with $KHSO_4$, dissolving in water, and fractionally ppg. by $HgNO_3$Aq; the first pps. are then decomposed by *aqua regia*, the WO_3 thus obtained is dried and fused with Na_2CO_3, the fused mass is dissolved in water, tartaric acid is added, and H_2S is passed into the solution; the filtrate from ppd. MnS, &c., is boiled till H_2S is expelled, and is then fractionally ppd. by $HgNO_3$Aq; the later pps. are collected, washed, and decomposed by heating in an open vessel. For a method of preparing WO_3 from *wolframite* *v. Preparation* of Tungsten, p. 797.

Properties.—A heavy, canary-yellow powder; becoming orange-coloured when heated (Roscoe, *C. N.* 25, 73). Crystalline WO_3 is described as wine-yellow, very lustrous, rhombic tablets (Nordenskjold, *P.* 114, 612). A trace of Na tungstate gives a green colour to WO_3 (R., *l.c.*). S.G.: amorphous, 7·13 to 7·16 (Zettnow, *P.* 130, 16, 240; Karsten, *S.* 65, 394); crystalline, 7·23 at 17° (Z., *l.c.*); 6·38 (N., *l.c.*). S.H. (8° to 98°) ·07983 (Regnault, *A. Ch.* [3] 1, 129); (22° to 52°) ·0894 (Kopp, *T.* 1865. 71). Melts readily in the blowpipe (Riche, *A. Ch.* [3] 50, 29); can be sublimed by mixing with Na_2CO_3 and heating to whiteness (Debray, *C. R.* 55, 287); also by strongly heating in HCl (Schafarik, *W. A. B.* 47, 246). Not decomposed at m.p. of Pt (c. 1750°) (Read, *C. J.* 65, 313 [1894]). On exposure to light WO_3 turns greenish, owing to partial reduction (Roscoe, *l.c.*; *cf.* Liesegang, *C. C.* 1865. 943) WO_3 is insoluble in water or acids, even in boiling conc. H_2SO_4; it dissolves in hot KOHAq, NH_3Aq, or K_2CO_3Aq, also in molten K_2CO_3, $KHSO_4$, or K_2WO_4; also in molten alkali chlorides, in air, with evolution of Cl (Schultze, *J. pr.* [2] 21, 437, 441). WO_3 acts as an acidic oxide, forming tungstates (*v.* Tungsten oxyacids, p. 802).

Reactions.—1. Heated in *hydrogen*, WO_3 is reduced to the blue oxide, then to WO_2, and finally to W (*v.* Blue oxide of tungsten, p. 800; Tungsten dioxide, p. 800; and Tungsten, p. 797).—2. Reduction to WO_2 or W is effected by heating with *carbon*.—3. Heated with *potassium* or *sodium*, WO_3 gives W.—4. Reduction to the blue oxide, and then to WO_2, is brought about by *zinc and hydrochloric acid*, by *stannous chloride*, and also by heating with water and different *organic compounds*.—5. Heating with *carbon* in *chlorine* produces WO_2Cl_2 and $WOCl_4$.—6. $WOCl_4$ is formed by passing vapour of *tungsten hexachloride* over heated WO_3 (Roscoe, *C. N.* 25, 63).—7. A mixture of WO_3 and *calcium chloride* heated to redness in *carbon dioxide* gives WO_2Cl_2 (Schultze, *J. pr.* [2] 21, 441).—8. Mixed with *carbon* and heated in *bromine*, WO_3 gives $WOBr_4$; and WO_2Br_2 is formed by passing vapour of *tungsten pentabromide* over hot WO_3 (Roscoe, *l.c.* p. 73).—9. WO_3 is said to dissolve in *molten alkali chlorides*, in air, giving off Cl; heated in absence of air (in a stream of CO_2) with *chlorides of calcium, cobalt, iron, magnesium*, or *nickel*, it is said to give WO_2Cl_2 and MWO_4 (Schultze, *l.c.*).—10. Heating with *phosphorus pentachoride* produces WCl_6 and $POCl_3$ (Teclu, *A.* 187, 255): but WO_2Cl_2 and $WOCl_4$ are also formed, according to the relative masses of WO_3 and PCl_5, and the temperature (Schiff, *A.* 197, 185).—11. WO_2Cl_2, $WOCl_4$, and CO_2 are formed by heating WO_3 in vapour of *carbon tetrachloride* (Watts a. Bell, *C. J.* 33, 442).—12. Compounds of W with N, H, and O (*v.* p. 800) are formed by heating WO_3 in *ammonia*; and a compound of W with N and O is probably produced by heating WO_3 with *sal ammoniac* (*v.* p. 800).—13. WS_3

*is formed by passing **sulphur vapour**, or **hydrogen sulphide**, over WO_2 heated to whiteness (Berzelius); also by heating to redness a mixture of WO_2 with 6 pts. of mercuric sulphide (B.; Brock, J. pr. 54, 254).*

HYDRATES OF TUNGSTEN TRIOXIDE. Various compounds of the form $WO_3.xH_2O$ have been isolated; as these compounds act as acids, they are described under TUNGSTEN OXYACIDS.

Tungsten oxyacids, salts, and derivatives of. Several hydrates of WO_3 that react as acids are known. WO_3 also combines with many acidic oxides—such as P_2O_5, B_2O_3, SiO_2, &c.—and the compounds so formed combine with basic oxides to form salt-like bodies.

TUNGSTIC ACIDS. The hydrates of WO_3 fall into two classes: *tungstic acids*, which are insoluble, or nearly insoluble, in water; and *metatungstic acids*, which dissolve in water.

TUNGSTIC ACIDS. The *monohydrate* $WO_3.H_2O$, or *orthotungstic acid* $WO_2(OH)_2$, is obtained by dissolving WO_3 in hot alkali or alkaline carbonate solutions, and boiling these solutions with excess of a mineral acid. It is also said to be obtained by decomposing an ammoniacal solution of WO_3 by Cl (Dumas, *A. Ch.* [3] 55, 144); and also by boiling powdered *wolframite* with *aqua regia*. This acid is a yellow solid; it reddens litmus; is insoluble, or almost insoluble, in water. According to Braun (*J. pr.* 91, 39), it is changed to $2WO_3.H_2O$ at 100°; according to Zettnow (*P.* 130, 16, 240), this change is effected at 50°. The acid is slowly reduced by Zn and HClAq, the final product being WO_2 (O. v. d. Pfordten, *B*, 16, 508).

The *dihydrate* $WO_3.2H_2O$ is said to be formed by adding a mineral acid to a dilute solution of an alkali tungstate M_2WO_4, and drying in the air; also by decomposing WCl_6, $WOCl_4$, or WO_2Cl_2 by water (Forcher, *W. A. B.* 44 [2], 173; *cf.* Riche, *A. Ch.* [3] 50, 36; Anthon, *J. pr.* 9, 6). Forms $WO_3.H_2O$ by drying over H_2SO_4 (Braun, *J. pr.* 91, 39). This hydrate is described as an amorphous, white solid; reddens litmus; somewhat soluble in water, but insoluble if a little acid is present. By boiling with dilute acids is said to give $WO_3.H_2O$.

The *hemihydrate* $2WO_3.H_2O$, or *ditungstic acid* $H_2W_2O_7$, is said by Braun (*l.c.*) to be formed by heating the monohydrate to 100°; the change is complete at 50° according to Zettnow (*P.* 130, 16, 240).

METATUNGSTIC ACIDS. Acids of the composition $4WO_3.xH_2O$ are obtained by decomposing hot conc. $BaW_4O_{13}Aq$ by the equivalent quantity of H_2SO_4, filtering from $BaSO_4$, and evaporating (Scheibler, *J. pr.* 83, 310); also by decomposing $PbW_4O_{13}Aq$ by H_2S, filtering, and evaporating (Forcher, *W. A. B.* 44 [2], 173). The composition of the acid formed by evaporating *in vacuo* over H_2SO_4 is probably $H_2W_4O_{13}.?H_2O$ (Scheibler, *l.c.*; *cf.* Persoz, *C. R.* 34, 135; Lotz, *A.* 91, 52). BaW_4O_{13} is obtained by ppg. a hot conc. solution of $(NH_4)_2W_4O_{13}$ by $BaCl_2Aq$; PbW_4O_{13} by ppg. $(NH_4)_2W_4O_{13}Aq$ by $Pb(C_2H_3O_2)_2Aq$; $(NH_4)_2W_4O_{13}$ is formed by boiling $(NH_4)_2WO_4$ with WO_3Aq and evaporating.

According to Zettnow (*P.* 130, 16, 240), the pp. obtained by decomposing Na_2WO_4Aq by a mineral acid has the composition
$4WO_3.H_2O(=H_2W_4O_{13})$ after drying at 200°.

Metatungstic acid crystallises in sulphur-yellow octahedra; the acid is readily soluble in water, forming a very sour, intensely bitter liquid. A conc. solution gives a pp. of $WO_3.2H_2O$ on standing; when a dilute solution is boiled it coagulates and gives a pp. of white $WO_3.2H_2O$, and then of yellow $WO_3.H_2O$. The heats of neutralisation of $H_2W_4O_{13}Aq$ by Na_2OAq, K_2OAq, BaOAq, and SrOAq are given by Péchard (*C. R.* 108, 1167); the values are nearly the same as those for HNO_3Aq and H_2SO_4Aq. When four equivalents of base are added to $H_2W_4O_{13}Aq$, orthotungstates M_2WO_4 are formed (P., *l.c.*).

By long-continued boiling 2 pts. Na_2WO_4 with 1 pt. As_2O_5, evaporating, treating with alkali solution, and repeatedly crystallising, Lefort (*A. Ch.* [5] 25, 205) obtained fine, very lustrous crystals, which were very soluble in water and in alcohol; to this acid L. gave the composition $H_2W_4O_{13}.6H_2O$, and the name *luteo-metatungstic acid.*

Colloidal (*meta?*) *tungstic acid.* By adding to 5 p.c. Na_2WO_4Aq rather more HClAq than sufficed to neutralise the Na, and dialysing, with addition from time to time of a little HClAq, Graham (*C. J.* 17, 318) obtained a solution in water of tungstic acid. The solution was not gelatinised by acids, salts, or alcohol at the ordinary temperature; it remained clear at 200°. According to Sabanéeff (*J. R.* 21, 515; Abstract in *C. J.* 58, 1215), determinations of the freezing-point of an aqueous solution of Graham's soluble acid point to the formula $3WO_3.H_2O(=H_2W_3O_{10})$. As the values for mol. w. obtained by S. varied from 679 to 995, there seems little reason for adopting the formula $H_2W_3O_{10}$ (713) rather than $H_2W_4O_{13}$ (944).

TUNGSTATES. A great many tungstates have been prepared. The proportion of basic to acidic radicle varies much in these compounds. The better studied tungstates have been divided into three classes—*orthotungstates* $MO.WO_3$, *paratungstates* $3MO.7WO_3$, or perhaps $5MO.12WO_3$, and *metatungstates* $MO.4WO_3$—but as many tungstates are known which do not fit into any of these classes it seems better to adopt a nomenclature and arrangement similar to those employed for the molybdates (*cf.* vol. iii. p. 423), based on the number of WO_3 radicles in the salts. Arranging the tungstates on this plan we get the following table. R = divalent metal, or two atoms of a monovalent metal.

(Ortho) *Monotungstates* $RO.WO_3$ or RWO_4; derived from the acid H_2WO_4.

Ditungstates $RO.2WO_3$ or RW_2O_7; derived from the acid $H_2W_2O_7$.

$$\textbf{(Para)}\begin{cases}3{:}7\ \textit{tungstates}\ 3RO.7WO_3\ \text{or}\ R_3W_7O_{24}.\\ 5{:}12\ \textit{tungstates}\ 5RO.12WO_3\ \text{or}\\ \quad R_5W_{12}O_{41}.\end{cases}$$

2:5 *tungstates* $2RO.5WO_3$ or $R_2W_5O_{17}$.
3:8 *tungstates* $3RO.8WO_3$ or $R_3W_8O_{27}$.

Tritungstates $RO.3WO_3$ or RW_3O_{10}; ?derived from Graham's colloidal acid.

(Meta) *Tetratungstates* $RO.4WO_3$ or RW_4O_{13}; derived from the acid $H_2W_4O_{13}$.

Pentatungstates $RO.5WO_3$ or RW_5O_{16}.
Hexatungstates $RO.6WO_3$ or RW_6O_{19}.
Octotungstates $RO.8WO_3$ or RW_8O_{25}.

The tungstates which have been most thoroughly examined are the monotungstates or orthotungstates; the paratungstates, which

are either 3:7 or 5:12 salts; and the tetra- or metatungstates.

For *thiotungstates* v. TUNGSTEN, THIO-ACIDS AND SALTS OF, p. 810.

ORTHOTUNGSTATES OR MONOTUNGSTATES, **$RO.WO_3$ or RWO_4.** Salts of H_2WO_4, which is the monohydrate of WO_3. The alkali orthotungstates are obtained by dissolving WO_3 or $WO_3.H_2O$ in alkali or alkali-carbonate solutions; or by fusing WO_3 with alkalis, alkaline carbonates, or alkali acid sulphates, and dissolving in water. The other orthotungstates are generally obtained from solutions of the alkali salts by ppn.; also by strongly heating WO_3 with metallic oxides or carbonates; also by fusing the alkali salts with metallic chlorides, and washing with water (Manross, *A.* 81, 243; 82, 356; Geuther a. Forsberg, *A.* 120, 268; Schultze, *A.* 126, 56). The orthotungstates are insoluble in water, except the alkali salts and the Mg salt. Solutions of the alkali salts give pps. of $WO_3.H_2O$ (yellow) or $WO_3.2H_2O$ (white), with dilute H_2SO_4Aq, HClAq, HNO_3Aq, or H_3PO_4Aq; the pp. by HClAq dissolves in a considerable excess of conc. HClAq (Mallet, *C. J.* 28, 1228); cold solutions of metatungstates are not ppd. by acids. According to Marignac (*A. Ch.* [3] 69, 5) the pp. obtained by adding an acid to a solution of an alkali tungstate sometimes contains alkali, and sometimes the ppg. acid, according to the relative quantity of acid used, the dilution, and probably also the temperature. Orthotungstates which are insoluble in water, and the metals of which form carbonates that are insoluble in alkali carbonate solutions, can be brought into solution by fusion with alkali carbonates and treatment with water.

Solutions of orthotungstates give a white pp. with $HgNO_3Aq$; a bluish-white pp. with $Cu(NO_3)_2Aq$; a brown flocculent pp. on adding K_4FeCy_6Aq, after adding HClAq; no pp. with tincture of galls until an acid is added, when a copious chocolate-coloured pp. is formed; and a yellow pp. with $SnCl_2Aq$, which pp. turns blue when it is warmed with a little HClAq or H_2SO_4Aq. For the reactions with Zn and acid, and with KCNSAq, Zn and acid, v. TUNGSTEN, DETECTION OF, p. 798.

Barium orthotungstate $BaWO_4$. Prepared by fusing 7 parts $BaCl_2$ with 4 parts NaCl and 2 parts Na_2WO_4, and washing with water; white octahedra (Geuther a. Forsberg, *A.* 120, 270); fusible with difficulty (Zettnow, *P.* 130, 256); S.G. 5·0035 at 13·5° (Clarke, *Am. S.* [3] 14, 281). *Hydrates*: (1) $2BaWO_4.H_2O$, by ppg. a hot solution of $3Na_2O.7WO_3$ by BaOAq (Scheibler, *B. B.* 1860. 208); (2) $BaWO_4.H_2O$ and $BaWO_4.2H_2O$, by adding four equivalents BaO in solution to $H_2W_4O_{13}Aq$ (Péchard, *C. R.* 108, 1167).

Cadmium orthotungstate $CdWO_4$. Obtained as a yellow crystalline powder by fusing together 11 parts $CdCl_2$, 16 parts NaCl, and 4 parts Na_2WO_4 (G. a. F., *l.c.*, p. 268; Z., *l.c.*, p. 240). The *dihydrate* $CdWO_4.2H_2O$ is obtained by ppg. a solution of a salt of Cd by Na_2WO_4Aq (Anthon, *J. pr.* 8, 399; 9, 337; Smith a. Bradbury, *B.* 24, 2935).

Calcium orthotungstate $CaWO_4$. Occurs native as *scheelite*, S.G. 6·02 (Bernoulli, *J.* 13, 783). Obtained by adding K_2WO_4Aq to $CaCl_2Aq$. Quadratic octahedra are formed by fusing Na_2WO_4 with excess of $CaCl_2$ (Manross, *A.* 81, 243; 82, 348); also by heating the ppd. salt with CaO in a stream of HCl (Debray, *C. R.* 55, 287).

Chromium orthotungstate $Cr_2(WO_4)_3.20H_2O$. Obtained as a green pp. by adding Na_2WO_4Aq to $CrCl_3Aq$; loses $13H_2O$ at 100° (Lotz, *A.* 91, 66).

Cobalt orthotungstate $CoWO_4.2H_2O$. A violet powder; obtained by ppg. Co salt solutions by K_2WO_4Aq (Anthon, *J. pr.* 9, 344).

Copper orthotungstate $CuWO_4.2H_2O$. A green powder, melting at a red heat and cooling to chocolate-coloured crystals; formed by ppg. Cu salts by Na_2WO_4Aq (A., *l.c.*).

Ferrous orthotungstate $FeWO_4$. Obtained as opaque crystals by heating WO_3 and Fe_2O_3 in a stream of HCl (Debray, *C. R.* 55, 288); also by fusing 2 parts $FeCl_2$, 2 parts NaCl, and 1 part Na_2WO_4 (Geuther a. Forsberg, *A.* 120, 278; Zettnow, *P.* 130, 30). The *trihydrate* $FeWO_4.3H_2O$ was obtained by Anthon (*J. pr.* 9, 343) as a brown powder by ppg. a ferrous salt by K_2WO_4Aq. *Double compounds* of the form $mFeWO_4.nMnWO_3$ with the ratios $m:n = 7:1$, 4:1, 3:1, 3:2, 1:2, and 1:7 were obtained by fusing $FeCl_2$, $MnCl_2$, NaCl, and Na_2WO_4 in varying proportions (G. a. F., *l.c.* p. 270; *cf.* Z., *l.c.* p. 250). *Wolframite* has approximately the composition $FeO.MnO.WO_3$.

Lead orthotungstate $PbWO_4$. Occurs native as *scheelctine*; obtained, as a white pp., by adding K_2WO_4Aq to solution of a salt of Pb (A., *l.c.*, p. 342); quadratic octahedra are formed by fusing 10 parts Na_2WO_4 with 47 parts $PbCl_2$, S.G. 8·235 (Manross, *A.* 82, 357).

Magnesium orthotungstate $MgWO_4$. Formed, in white octahedra, by fusing 2 parts $MgCl_2$ with 2 parts NaCl and 1 part Na_2WO_4 (G. a. F., *l.c.* p. 272).

Manganese orthotungstate $MnWO_4$. Garnet-brown, lustrous, rhombic crystals; S.G. 6·7; obtained by fusing 2 parts $MnCl_2$, 2 parts NaCl, and 1 part Na_2WO_4 (G. a. F., *l.c.*; Z., *l.c.*).

Mercurous orthotungstate Hg_2WO_4. A yellow pp., formed by adding solution of a mercurous salt to solution of an alkali tungstate (A., *l.c.*).

Nickel orthotungstate $NiWO_4$. Formed by fusing 2 parts $NiCl_2$ with 2 parts NaCl and 1 part Na_2WO_4; brown, lustrous crystals (Schultze, *A.* 126, 56); S.G. 6·8845 at 20·5°, 6·8522 at 22° (Clarke, *Am. S.* [3] 14, 281). The *hexahydrate*, $NiWO_4.6H_2O$, is obtained by ppn. (A., *l.c.*).

Potassium orthotungstate K_2WO_4. White, triclinic needles; obtained by boiling WO_3 with an equivalent weight of KOHAq or K_2CO_3Aq, and evaporating (Marignac, *A. Ch.* [3] 69, 18; Anthon, *J. pr.* 8, 399; 9, 337). Decrepitates when heated; melts at red heat (M., *l.c.*), taking up CO_2 (Ullik, *W. A. B.* 56 [2], 148; *cf.* Knorre, *J. pr.* 27, 89). Various *hydrates* are obtained by crystallising a solution of WO_3 in K_2CO_3Aq under different conditions (M., *l.c.*; A., *l.c.*; Riche, *A. Ch.* [3] 50, 45).

Silver orthotungstate Ag_2WO_4. A pale-yellow, amorphous pp. by adding Na_2WO_4Aq to solution of a salt of Ag; melts below redness, and becomes crystalline on cooling; easily soluble in HNO_3Aq; soluble in NH_3Aq (Zettnow, *P.* 130, 30; *cf.* Muthmann, *B.* 20, 984; Wöhler a.

Rautenberg, A. 114, 120). By evaporating a solution in NH_3Aq over CaO and NH_4Cl, Widmann obtained the compound $Ag_2WO_4.4NH_3$ (*Bl.* [2] 20, 64).

Sodium orthotungstate $Na_2WO_4.2H_2O$. Obtained by crystallising a solution of WO_3 in the equivalent quantity of NaOHAq or Na_2CO_3Aq. Transparent, colourless, rhombic tablets (Marignac, *A. Ch.* [3] 69, 22). Effloresces *in vacuo*, or in dry air. Loses all H_2O at 100°. S.G. 3·2588 at 17·5°, 3·2314 at 19°; S.G. of Na_2WO_4 = 4·1743 at 20·5°, 4·1833 at 18·5° (Clarke, *Am. S.* [3] 14, 281). Solubility = 41 at 0°, 55 at 15°, 123·4 at 100° (Riche, *J. pr.* 69, 10). For S.G. of Na_2WO_4Aq of different concentrations, *v.* Franz (*J. pr.* [2] 4, 238). For E.C. of Na_2WO_4Aq *v.* Walden (*Z. P. C.* 1, 529).

Strontium orthotungstate $SrWO_4$. Obtained by ppn. (Anthon, *l.c.*); also by fusing 2 parts $SrCl_2$, 2 parts NaCl, and 1 part Na_2WO_4 (Zettnow, *l.c.*; Schultze, *A.* 126, 56).

Zinc orthotungstate $ZnWO_4$. Colourless tablets; formed by fusing 2 parts $ZnCl_2$ with 2 parts NaCl and 1 part Na_2WO_4 (Geuther a. Forsberg, *A.* 120, 270; *cf.* Zettnow, *P.* 130, 240).

PARATUNGSTATES. A number of acid tungstates have been isolated, the composition of which is expressed by one of the formulæ $3RO.7WO_3$ or $5RO.12WO_3$. The former formula was given by Lotz (*A.* 91, 49) and Scheibler (*J. pr.* 83, 273); the latter formula by Laurent (*A. Ch.* [3] 21, 54) and Marignac (*A. Ch.* [3] 69, 5). The two formulæ represent salts of almost identical composition, and no way has been found of deciding which formula is the better (*cf.* Knorre, *J. pr.* [2] 27, 83). The acid tungstates of this series are more easily formed and crystallise better than the other acid salts; they are generally called *paratungstates*, following the suggestion made by Marignac.

The alkali paratungstates are obtained by saturating hot alkali solutions with WO_3 and crystallising; most of the other paratungstates are prepared by ppn. from solutions of the alkali salts. The alkali salts are soluble in water, the other salts are insoluble. Solutions of alkali paratungstates give, with dilute HClAq, white pps. which become yellow on boiling ($WO_3.xH_2O$). Metatungstates, $RO.4WO_3$, are formed by gradually adding HClAq to boiling solutions of paratungstates; meta- salts are also formed by boiling para- salts with $WO_3.H_2O$. Solutions of paratungstates are not ppd. by SO_2Aq, HIAq, citric, tartaric, or oxalic acid; but the presence of one of these acids does not hinder ppn. by HClAq. Solutions of alkali paratungstates give pps. with salts of almost all the heavy metals. H_2S reacts with alkali paratungstates in solution to form solutions of thiotungstates which give brown pps. with acids, soluble in $(NH_4)_2SAq$. Paratungstates readily react with H_3PO_4, H_3AsO_4, &c., to form complex acids (*v.* p. 807), solutions of which are not ppd. by acids, except these are added in considerable excess; solutions of paratungstates are, therefore, not ppd. by HClAq in presence of H_3PO_4, H_3AsO_4, $H_2B_2O_4$, &c. For the reactions of paratungstates with PtO_4H_4 *v.* Rosenheim (*B.* 24, 2397; the reaction is rather indefinite).

If the simpler (3:7) formula is adopted, the ***paratungstates are represented as*** $3R^I_2O.7WO_3$, $3R^{II}O.7WO_3$, *and* $R^{III}_2O_3.7WO_3$, *i.e.* as salts of the hypothetical acid $H_6W_7O_{24}$, wherein 6H are replaced by $6R^I$, $3R^{II}$, or $2R^{III}$; if the less simple formula (5:12) is adopted, the paratungstates of monovalent and divalent metals are regarded as salts of the hypothetical acid $H_{10}W_{12}O_{41}$ ($=12WO_3.5H_2O$), wherein 10H are replaced by $10R^I$ or $5R^{II}$; paratungstates of R^{III} must be represented in this scheme by the complicated formula $R^{III}_{10}(W_{12}O_{41})_3$. In the paratungstates which have been best examined $R^I = NH_4$, Li, Hg, K, Ag, and Na; R^{II} = Ba, Cd, Ca, Co, Cu, Pb, Mg, Mn, Ni, Sr, and Zn; and R^{III} = Al and Cr. The simpler formulæ are employed in the descriptions of the individual salts.

Aluminium paratungstate $Al_2W_7O_{24}.9H_2O$. A flocculent pp., drying to gum-like lumps; obtained by adding $(NH_4)_6W_7O_{24}Aq$ to a solution of a salt of Al (Lotz, *A.* 83, 65; Anthon, *J. pr.* 8, 399; 9, 337).

Ammonium paratungstate $(NH_4)_6W_7O_{24}.6H_2O$. Obtained by dissolving $WO_3.H_2O$ in NH_3Aq and crystallising at the ordinary, or a little above the ordinary, temperature (Lotz, *A.* 91, 55). Crystallises in white, rhombic needles (Marignac, *A. Ch.* [3] 69, 25; Kerndt, *J. pr.* 41, 190); also in rhombic tablets (M., *l.c.*); and is, therefore, dimorphous. Solubility = 2·8 to 4·5 at 15°–22°; when the solution is boiled the very soluble meta- salt $(NH_4)_2W_4O_{13}$ is formed. Loses 3·9 p.c. H_2O at 100°; when heated to redness the blue oxide of W remains mixed with compounds containing N (M., *l.c.*). Marignac (*l.c.*) gave the formula $(NH_4)_{10}W_{12}O_{41}.11H_2O$ to this salt; Berzelius, and Anthon (*l.c.*) gave the formula $(NH_4)_2W_2O_7.H_2O$; and Riche (*v.* Marignac, *l.c.*) the formula $(NH_4)_2W_4O_{13}.5$ or $6H_2O$.

Various *double salts* have been isolated; with $Na_6W_7O_{24}$ (*v.* Knorre, *B.* 19, 821; Gibbs, *Am.* 7, 236); with $K_6W_7O_{24}$ (*v.* Laurent, *A. Ch.* [3] 21, 59; Marignac, *A. Ch.* [3] 69, 55); with $Mg_3W_7O_{24}$ *v.* M. (*l.c.*), Lotz (*A.* 91, 61); with $Zn_3W_7O_{24}$ *v.* Lotz (*l.c.*); with $Cd_3W_7O_{24}$ *v.* L. (*l.c.*); with $Hg_3W_7O_{24}$ *v.* Anthon (*J. pr.* 8, 399; 9, 337).

Barium paratungstate $Ba_3W_7O_{24}.8H_2O$. A white pp. formed by adding $(NH_4)_6W_7O_{24}Aq$ to excess of $BaCl_2Aq$, washing and drying over H_2SO_4 (Lotz, *A.* 93, 60; *cf.* Knorre, *B.* 18, 327; 19, 820). Forms a *double salt* with $Na_6W_7O_{24}$ (Scheibler, *J. pr.* 83, 314).

Cadmium paratungstate $Cd_3W_7O_{24}.16H_2O$; white needles, obtained by adding $Na_6W_7O_{24}Aq$ to excess of solution of a salt of Cd (Gonzalez, *J. pr.* [2] 36, 44).

Calcium paratungstate $Ca_3W_7O_{24}.18H_2O$; a crystalline pp. formed by ppg. excess of $CaCl_2Aq$ by $Na_6W_7O_{24}Aq$, and drying in the air (Knorre, *B.* 18, 328). Forms a *double salt* with $Na_6W_7O_{24}$ (Gonzalez, *l.c.*).

Chromium paratungstate $Cr_2W_7O_{24}.9H_2O$; a grey powder, obtained by heating $CrCl_3$ with $(NH_4)_6W_7O_{24}$; insoluble in water, but dissolves in $CrCl_3Aq$ (Lotz, *A.* 91, 66).

Cobalt paratungstate $Co_3W_7O_{24}.25H_2O$ (Gonzalez, *l.c.*); forms a *double salt* with $Na_6W_7O_{24}$ (G., *l.c.*).

Copper paratungstate $Cu_3W_7O_{24}.19H_2O$; a pale-green pp. formed by adding $Na_6W_7O_{24}Aq$ to excess of $CuSO_4Aq$ (Knorre, *B.* 19, 826; *v.* also Gonzalez, *J. pr.* [2] 36, 44). Forms a *double salt* with $Na_6W_7O_{24}$ (K., *l.c.*).

Lead paratungstate $Pb_3W_7O_{24}$; a white pp. formed by adding $(NH_4)_6W_7O_{24}Aq$ to $Pb(NO_3)_2Aq$ (Lotz, *A.* 91, 49). Forms a *double salt* with $Na_6W_7O_{24}$ (Gonzalez, *l.c.*).

Lithium paratungstate $Li_6W_7O_{24}.19H_2O$. Large prisms, unchanged in air; obtained by boiling the proper quantities of WO_3 and Li_2CO_3 in water, and allowing to crystallise (Scheibler, *J. pr.* 83, 321).

Magnesium paratungstate $Mg_3W_7O_{24}.24H_2O$; obtained by ppn. (Knorre, *B.* 19, 824). Forms a *double salt* with $Na_6W_7O_{24}$ (K., *l.c.*).

Manganese paratungstate $Mn_3W_7O_{24}.34H_2O$ (Gonzalez, *J. pr.* [2] 36, 44). Forms a *double salt* with $Na_6W_7O_{24}$ (K., *l.c.*).

Nickel paratungstate $Ni_3W_7O_{24}.14H_2O$ (Anthon, *J. pr.* 9, 344).

Potassium paratungstate $K_6W_7O_{24}.6H_2O$ (Marignac, *A. Ch.* [3] 69, 33, gave the formula $K_{10}W_{12}O_{41}.11H_2O$). Prepared by saturating hot KOHAq with $WO_3.xH_2O$, and allowing to cool; by boiling K_2WO_4 with H_2O; or by fusing *wolframite* with $\frac{2}{3}$ of its weight of K_2CO_3, boiling the product with water, saturating the aqueous solution with CO_2, and crystallising (M., *l.c.*). White rhombic crystals, isomorphous with the NH_4 salt (M., *l.c.*). Decomposed, by melting, to K_2WO_4 and $5K_2O.14WO_3$, without forming any meta- salt (Knorre, *J. pr.* [2] 27, 91). Solubility = 2·15 cold water, 6·6 boiling water.

Various *hydrates* have been obtained (*v.* Zettnow, *P.* 130, 241; *cf.* Lefort, *A. Ch.* [5] 9, 93; 15, 321; 17, 470; 25, 200). Forms *double salts* with $Na_6W_7O_{24}$ (*v.* Marignac, *A. Ch.* [3] 69, 55; Laurent, *A. Ch.* [3] 21, 54).

Silver paratungstate $Ag_6W_7O_{24}$; a yellow, crystalline pp. formed by adding $Na_6W_7O_{24}Aq$ to excess of $AgNO_3Aq$ (Gonzalez, *J. pr.* [2] 36, 44).

Sodium paratungstate $Na_6W_7O_{24}.16H_2O$. This formula is given by Scheibler (*J. pr.* 83, 285); the formula $Na_{10}W_{12}O_{41}$ is given by Laurent (*l.c.*), Marignac (*l.c.*), and by Friedheim a. Meyer, (*Zeit. f. anorg. Chemie*, 1, 81). Prepared by saturating hot NaOHAq, or Na_2CO_3Aq, with $WO_3.xH_2O$ and evaporating to the crystallising point; also by passing CO_2 into Na_2WO_4Aq until the reaction is only faintly alkaline. Large, well-formed, white, triclinic crystals (Scheibler, *l.c.*; Marignac, *A. Ch.* [3] 69, 39). Effloresces in air; loses c. $\frac{3}{4}$ of its H_2O over H_2SO_4; is dehydrated without decomposition at 300° (S., *l.c.*); heated to dull redness leaves a residue, insoluble in water, containing more than $5WO_3$ to Na_2O (M., *l.c.*; also Knorre, *J. pr.* [2] 27, 71). Melts above dull redness, giving Na_2WO_4 and $Na_2W_4O_{13}$ (meta- salt). Heated with water to 150° gives much meta- salt (K., *l.c.*). Solubility 8 to 9 at 35° to 40°; for the salts obtainable from an aqueous solution *v.* M. (*l.c.*), and also K. (*B.* 18, 2362). By boiling a solution with Na_2CO_3 transformation to Na_2WO_4 is complete (*v.* Schmidt, *Am.* 8, 16). A *hydrate* with $21H_2O$ has been obtained (M., *l.c.*). Forms *double salts* with $Sr_3W_7O_{24}$ (Gonzalez, *J. pr.* [2] 36, 44), and with $Zn_3W_7O_{24}$ (Knorre, *B.* 19, 823).

Strontium paratungstate $Sr_3W_7O_{24}.8H_2O$ (Knorre, *B.* 18, 327).

Zinc paratungstate $Zn_3W_7O_{24}.xH_2O$ (Gonzalez, *J. pr.* [2] 36, 44).

METATUNGSTATES OR TETRATUNGSTATES, $R^{II}O.4WO_3$ or $R^{II}W_4O_{13}$. Salts of the acid $H_2W_4O_{13}$ (*v.* METATUNGSTIC ACIDS, p. 802). The metatungstates may be obtained by causing metatungstic acid $H_2W_4O_{13}.xH_2O$ (*v.* p. 802) to interact with carbonates, chlorides, or nitrates; also by the reaction of a weak acid (H_3PO_4Aq is the best) with orthotungstates, the acid being added as long as the pp. of $WO_3.xH_2O$ which is at first formed re-dissolves; also from the alkali salts by double decomposition, or better from the Ba salt by interacting with sulphates; the alkali metatungstates are prepared by boiling solutions of the ortho-tungstates for some time with $WO_3.xH_2O$.

Most of the metatungstates are very soluble in water and are crystallisable from aqueous solutions; aqueous solutions are not ppd. by acids in the cold, but pps. are obtained after long standing or boiling. Metatungstates are changed to ortho- salts by excess of alkali; when strongly heated, orthotungstates are formed. Solutions of metatungstates are not ppd. by H_2S; $(NH_4)_2SAq$ gives a blue pp.; pps. are not obtained with salts of the heavy metals except Pb and Hg^I; K_4FeCy_6Aq does not form a pp.

Ammonium metatungstate $(NH_4)_2W_4O_{13}.8H_2O$. This formula is given by Scheibler (*J. pr.* 83, 303); more complicated formulæ are given by Marguerittе (*A. Ch.* [3] 17, 477), Laurent (*A. Ch.* [3] 21, 62), and Lotz (*A.* 91, 55). Obtained by boiling the para- salt $(NH_4)_6W_7O_{24}.xH_2O$ with $WO_3.H_2O$ (Margueritte, *A. Ch.* [3] 17, 477); also by boiling the para- salt with a little HNO_3Aq (Laurent, *A. Ch.* [3] 21, 62); also by heating the dry para- salt to 250°–300° (Scheibler, *J. pr.* 83, 304; *cf.* Persoz, *A. Ch.* [4] 1, 101; and Marignac, *A. Ch.* [4] 3, 71). White octahedra; effloresces in air; loses $7H_2O$ at 100°. Solubility in cold water = 120 (Lotz, *l.c.*), = 286 (Riche, *A. Ch.* [3] 50, 45). The solution is optically refractive. Insoluble in alcohol or ether. Forms a *double salt* with NH_4NO_3 (Marignac, *A. Ch.* [3] 69, 61).

Barium metatungstate $BaW_4O_{13}.9H_2O$. Obtained by adding $BaCl_2Aq$ to a hot conc. solution of $Na_2W_4O_{13}$ acidified by HClAq (Scheibler, *J. pr.* 83, 304). Crystallises in large, white, tetragonal octahedra; S.G. 4·298 at 14°; loses $6H_2O$ at 100°; easily soluble in hot water, decomposed by much cold water to WO_3 and $BaW_2O_{10}.6H_2O$, which dissolve again on heating.

Cadmium paratungstate $CdW_4O_{13}.10H_2O$. Lustrous, white octahedra; unchanged in air; obtained by decomposing $BaW_4O_{13}Aq$ by $CdSO_4Aq$ (S., *l.c.*, p. 273).

Calcium metatungstate $CaW_4O_{13}.10H_2O$. Quadratic octahedra; obtained by dissolving $CaCO_3$ in $H_2W_4O_{13}Aq$ and crystallising (S., *l.c.*, p. 314).

Cobalt metatungstate $CoW_4O_{13}.9H_2O$ (S., *l.c.* p. 317).

Copper metatungstate $CuW_4O_{13}.11H_2O$ (S., *l.c* p. 317).

Magnesium metatungstate $MgW_4O_{13}.8H_2O$ (S., *l.c.*).

Manganese metatungstate $MnW_4O_{13}.10H_2O$ (S., *l.c.* p. 273).

Mercurous metatungstate *$Hg_2W_4O_{13}.25H_2O$. Obtained, as a white pp., by adding $HgNO_3Aq$ to* solution of $H_2W_4O_{13}$ or a meta- salt (S., *l.c.*, p. 319).

Nickel metatungstate $NiW_4O_{13}.8H_2O$ (S., *l.c.*, p. 273).

Potassium metatungstate $K_2W_4O_{13}.8H_2O$. Lustrous octahedra; obtained by boiling $K_6W_7O_{24}Aq$ with $WO_3.xH_2O$; very soluble in hot water, considerably less soluble in cold water (S., *l.c.*, p. 303). A *pentahydrate* was obtained by Marignac (*A. Ch.* [4] 3, 71).

Silver metatungstate $Ag_2W_4O_{13}$. Obtained, as a crystalline crust, by adding $AgNO_3Aq$ to $Na_2W_4O_{13}Aq$, evaporating, separating from Ag_2WO_4, and evaporating again (S., *l.c.* p. 318).

Sodium metatungstate $Na_2W_4O_{13}.10H_2O$. Obtained by boiling $Na_6W_7O_{24}Aq$ with $WO_3.xH_2O$ and allowing to evaporate; white, lustrous octahedra; S.G. 3·8647 at 13°; very soluble in hot, but less in cold, water (S., *l.c*, p. 303).

Strontium metatungstate $SrW_4O_{13}.8H_2O$ (S., *l.c.* p. 314).

Zinc metatungstate $ZnW_4O_{13}.10H_2O$ (S., *l.c.* p. 273).

TUNGSTATES OTHER THAN ORTHO-, PARA-, AND META- SALTS.

Ditungstates. Salts of the form $R^I_2O.2WO_3 = R^I_2W_2O_7$. Salts of K and Na of this composition were said by Lefort (*A. Ch.* [5] 17, 470) to be formed by neutralising cold solutions of K_2WO_4 and Na_2WO_4 by acetic acid; Knorre (*J. pr.* [2] 27, 83) obtained only metatungstates, $R_2W_4O_{13}$, by this method.

Two to five tungstates. The existence of salts of the class $2R^I_2O.5WO_3 = R^I_4W_5O_{17}$ is doubtful. Marignac obtained a salt to which he gave the formula $Na_4W_5O_{17}.11H_2O$ along with the para- salt $Na_6W_7O_{24}.16H_2O$ (*A. Ch.* [3] 69, 50). The same salt seems to have been obtained by Lefort (*l.c.*; *cf.* Forcher a. Gibbs, *J.* 1880. 341) by adding acetic acid and alkali to Na_2WO_4Aq and allowing to stand for some time (*cf.* also Schmidt, *Am.* 8, 16).

Three to eight tungstates. A salt $(NH_4)_6W_8O_{27}.8H_2O = 3(NH_4)_2O.8WO_3.8H_2O$ seems to have been prepared by Marignac (*A. Ch.* [3] 69, 61).

Tritungstates $R^{II}O.3WO_3 = R^{II}W_3O_{10}$. Lefort (*A. Ch.* [5] 17, 470) prepared a salt to which he gave the formula $Na_2W_3O_{10}.6H_2O$, by pouring a boiling solution of $Na_2W_2O_7.6H_2O$ (obtained by adding acetic acid to Na_2WO_4Aq until the liquid shows an acid reaction) into boiling acetic acid, allowing to cool, separating the lower syrupy layer, and crystallising it. A corresponding salt $K_2W_3O_{10}.2H_2O$ was obtained by a similar method; and a series of tritungstates was prepared by mixing equivalent quantities of the Na salt and metallic acetates, in solution, and adding alcohol. L. describes the tritungstates as easily decomposing in aqueous solutions to di- and tetra- salts. The following salts were formed by L.:— $BaW_3O_{10}.4H_2O$; $CdW_3O_{10}.4H_2O$; $CaW_3O_{10}.6H_2O$; $CoW_3O_{10}.4H_2O$; $FeW_3O_{10}.4H_2O$; $PbW_3O_{10}.2H_2O$; $MgW_3O_{10}.4H_2O$; $MnW_3O_{10}.5H_2O$; $NiW_3O_{10}.4H_2O$; $K_2W_3O_{10}.2H_2O$; $Na_2W_3O_{10}.4H_2O$; $SrW_3O_{10}.5H_2O$. Knorre's experiments led him to regard Lefort's tritungstates as mixtures (*J. pr.* [2] 27, 83).

Penta- and octo- tungstates. Salts *of K and Na of the composition $R_2W_5O_{16}$ and $R_2W_8O_{25}$ are said to have been isolated*, the former by fusing mixtures of R_2WO_4 and WO_3, the latter by fusing $R_2W_4O_{13}$ with R_2WO_4 (Knorre, *J. pr.* [2] 27, 81, 91).

A few tungstates that do not find places in any of the foregoing classes have been described by different observers (*v.* especially Lefort, *A. Ch.* [5] 9, 93; 15, 324; 17, 470; 25, 200; also Schreibler, *J. pr.* 83, 237; Gonzalez, *J. pr.* [2] 36, 44; Knorre, *J. pr.* [2] 27, 93; Lotz, *A.* 91, 49; Feit, *B.* 21, 133; Cleve, *Bl.* [2] 43, 170; Högborn, *Bl.* [2] 42, 2).

PERTUNGSTATES. By boiling a solution of the paratungstate $Na_6W_7O_{24}.16H_2O$ with H_2O_2Aq, and then evaporating *in vacuo*, Péchard (*C. R.* 112, 1060) obtained small white crystals of a salt to which he gave the formula $Na_2O.W_2O_7.2H_2O = NaWO_4.H_2O$; and by treating $(NH_4)_6W_7O_{24}.6H_2O$ in a similar way he isolated the corresponding NH_4 pertungstate. According to P. these salts are decomposed by alkalis with evolution of O; solutions of them set free I from KIAq, and react with HClAq, giving off Cl.

TUNGSTEN BRONZES. Bright-coloured, lustrous, metal-like, crystalline solids, obtained by the action of reducers—such as H, coal-gas, Sn, or Fe—on tungstates of Li, K, or Na; also by the electrolysis of these tungstates when molten. The composition of these compounds, which are known as bronzes and are used as pigments, is represented by the formula $M_x(WO_3)_y$, where M = Li, K, or Na. The constitutions of the compounds are not known; they may be represented as compounds of tungstates with WO_2, by the general formula $xM_2O.yWO_3.zWO_2$; they may also be represented as compounds of M_2O with a radicle composed of W and O in a ratio greater than W:2O and less than W:3O—that is, as compounds of M_2O with oxides intermediate between WO_2 and WO_3. The tungsten bronzes are insoluble in most acids, also in alkali solutions.

Sodium tungsten bronzes. These compounds are formed by the interaction of Na tungstates and H (Wöhler, *P.* 2, 350), Sn (Wright, *A.* 79, 221), coal-gas (Schnitzler, *D. P. J.* 211, 484), Zn or Fe (Zettnow, *P.* 130, 261), or by electrolysing Na tungstates (Scheibler, *J. pr.* 83, 321). According to Philipp (*B.* 15, 499), the different processes yield the same bronze if the same tungstate is used, and the more WO_3 there is in the tungstate employed the richer in WO_3 is the bronze produced. All the compounds are insoluble in acids or alkalis; they dissolve in NaClOAq; heated with NH_3Aq and $AgNO_3Aq$ they give Ag and WO_3 (*cf.* P. a. Schwebel, *B.* 12, 2234; 15, 500; Knorre, *J. pr.* [2] 27, 51). These compounds are slowly oxidised to tungstates by heating to redness in air (K., *l.c.*). Philipp (*l.c.*) gave S.G. of all the sodium bronzes as 7·2 to 7·3 at 16° to 18°.

Purple-red bronze $Na_2W_3O_9 = Na_2O.2WO_3.WO_2 = Na_2O.W_3O_8 = Na_2WO_4.W_2O_5$. Prepared by fusing for c. half an hour a mixture of 10·9 g. Na_2CO_3, 71·7 g. WO_3 and 20 g. tinfoil, and boiling successively with H_2O, NaOHAq, and HClAq. Red cubes; the powder transmits green light when suspended in water (*P.*, *l.c.*).

Red-yellow bronze $Na_4W_5O_{15} = 2Na_2O.3WO_3.2WO_2 = 2Na_2O.W_5O_{13}$. Prepared by melting 60 to 80 g. of a mixture of Na_2WO_4 and WO_3 in the ratio $2Na_2WO_4:WO_3$, adding 30 g. tinfoil, and keeping molten for 1 to 2 hours. Red-yellow cubes; the powder is brownish yellow, and transmits blue light when suspended in water (P., *l.c.*).

Gold-yellow bronze $Na_5W_6O_{18} = 5Na_2O.7WO_3.5WO_2 = 5Na_2O.W_{12}O_{31}$. Prepared by heating $Na_2W_2O_7$ to dull redness in H, powdering and again heating in H, and then boiling with H_2O, HClAq, and Na_2CO_3Aq successively. Golden yellow, crystalline powder (P., *l.c.*; *cf.* Wöhler, *P.* 2, 350; Wright, *A.* 79, 221).

Blue bronze $Na_2W_5O_{15} = Na_2O.4WO_3.WO_2 = Na_2O.W_5O_{14}$. Prepared by fusing Na_2WO_4 with more than $2WO_3$, and adding tinfoil; also by melting $Na_6W_7O_{24}$ (paratungstate) and electrolysing with 6 Zn-Pt elements (P., *l.c.*; Scheibler, *J. pr.* 83, 321; *cf.* Knorre, *J. pr.* [2] 27, 49; and Zettnow, *P.* 130, 261). Dark-blue cubes, with a red sheen; S.G. 7·28 at 17°.

Potassium tungsten bronzes. The compound $K_2W_4O_{12} = K_2O.3WO_3.WO_2 = K_2O.W_4O_{11}$ seems to be the only one of this class that has been isolated. Prepared by fusing K_2WO_4 with WO_3 and adding tinfoil; also by fusing K_2CO_3 with from $3WO_3$ to $4WO_3$, and reducing by H or coal gas; also by electrolysing a molten mixture of K_2WO_4 and WO_3. Reddish-violet prisms, giving a blue powder which transmits greenish light when suspended in water; S.G. c. 7·1 (Laurent, *A. Ch.* [2] 67, 219; Zettnow, *P.* 130, 262; Knorre, *J. pr.* [2] 27, 63).

Lithium tungsten bronzes. A compound of this class, probably $Li_2W_5O_{15}$, is obtained by fusing $Li_6W_7O_{24}$ (paratungstate) with tin. Dark-blue crystals (Scheibler, *J. pr.* 83, 321; Knorre, *l.c.*, p. 69; Feit, *B.* 21, 133).

A *potassium sodium bronze* and a *potassium lithium bronze* have been obtained (Knorre, *l.c.* p. 66; Feit, *l.c.*).

COMPLEX TUNGSTIC ACIDS AND SALTS. Tungstic oxide WO_3 combines with several anhydrides, *e.g.* B_2O_3, P_2O_5, As_2O_5, SiO_2, &c., and water, to form acidic compounds, and also with these anhydrides and basic oxides to form salt-like compounds; the whole of these compounds are usually grouped together as *complex tungstic acids* and *complex tungstates*, and they are divided into such classes as *arsenotungstates*, *phosphotungstates*, &c.

ANTIMONOSOTUNGSTIC ACIDS AND SALTS. According to Lefort (*A. Ch.* [5] 17, 487), the compounds $Sb_2O_3.5WO_3.4H_2O$ and $Sb_2O_3.6WO_3.8H_2O$ are formed by dissolving tartar emetic in $Na_2O.3WO_3Aq$ and $Na_2O.2WO_3Aq$ respectively. Gibbs (*Am.* 7, 392) obtained
$4BaO.6Sb_2O_3 22WO_3.36H_2O$ and
$6K_2O.4Sb_2O_3.12WO_3.25H_2O$.

ARSENOTUNGSTIC ACIDS AND SALTS. Compounds of the form $As_2O_5 16WO_3.xH_2O$ have been obtained by Kehrmann (*A.* 245, 45; *cf.* Fremery, *B.* 17, 296); and series of compounds of As_2O_5 with WO_3 and basic oxides (Na_2O, K_2O, BaO, &c.), in which the ratio of $As_2O_5:WO_3$ is 1:6 and 1:3, have been described by Gibbs (*Am.* 7, 313). Compounds of WO_3 with As_2O_3 and bases, and also with As_2O_3 and As_2O_5 and bases, and finally with As_2O_3 and P_2O_5 and bases, are described by Gibbs (*l.c.*).

BOROTUNGSTIC ACIDS AND SALTS. Two compounds of B_2O_3 and WO_3 have probably been isolated, in which the ratios of the oxides are 1:14 and 1:9 respectively; compounds of each of these with bases are known (Klein, *A. Ch.* [5] 28, 350).

Borotungstic acid and salts $B_2O_3.14WO_3.xH_2O$. A solution containing B_2O_3 and WO_3 in the ratio 1:14 is obtained by boiling Na_2WO_4Aq with B_2O_3Aq, ppg. by $HgNO_3Aq$, decomposing the pp. by H_2S, and expelling H_2S from the filtrate by warming (for details *v.* K., *l.c.*). Compounds of the form $xMO.B_2O_3.14WO_3.yH_2O$ have been formed, where $x = 2$, 3, and 4, and M is Ba, K_2, Ag_2, Na_2 and Sr.

Tungstoboric acid and salts. The compound $B_2O_3.9WO_3.xH_2O$, usually known as tungstoboric acid, is obtained in yellowish octahedra by evaporating the solution of borotungstic acid. A considerable number of compounds of bases with B_2O_3 and WO_3, in the ratio $B_2O_3:9WO_3$, has been obtained; most of them are of the form $2MO.B_2O_3.9WO_3.xH_2O$, $M = (NH_4)_2$, Ba, Cd, Ca, Co, Cu, Li_2, Mg, Mn, Hg_2, Ni, K_2, Na_2, Tl_2; a few salts $2M_2O_3.B_2O_3.9WO_3.xH_2O$ ($M = Al$ or Cr) are also described by Klein (*l.c.*).

FLUOTUNGSTATES *and allied compounds*; *v.* TUNGSTOXYFLUORIDES (p. 799).

IODOTUNGSTATES. Blomstrand (*J. pr.* 40, 327) described a compound $2K_2O.I_2O_5.2WO_3.3H_2O$, obtained by adding the calculated quantity of HIO_3 to K_2WO_4Aq.

PHOSPHOTUNGSTIC ACIDS AND SALTS. The oxides WO_3 and P_2O_5 combine in several proportions, in presence of H_2O, to form complex acids which contain large quantities of WO_3 relatively to the P_2O_5. A great many compounds are known containing WO_3 and P_2O_5 combined with basic oxides.

Phosphotungstic acids. Compounds of the form $P_2O_5.xWO_3.yH_2O$; compounds wherein $x = 24$, 21, 20, 16, and 12 seem to have been isolated. The existence of these compounds was made known by Scheibler (*B.* 5, 802); they have been investigated chiefly by Gibbs (*Am.* 2, 217, 281; 4, 377; 5, 361, 391; 7, 313, 392; Péchard, *C. R.* 109, 301; 110, 754; and Kehrmann, *B.* 20, 1805, 1811; 24, 2326; 25, 1966; *A.* 245, 45; *Zeit. f. anorg. Chemie*, 1, 428; also Drechsel, *B.* 20, 1452; and Brandhorst a. Kraut, *A.* 249, 373). The phosphotungstic acids are obtained by boiling H_3PO_4Aq with $H_2W_4O_{13}.xH_2O$ (meta- acid); by decomposing the mercurous salts by HClAq; and by boiling $Na_6W_7O_{24}.xH_2O$ (para- salt) with Na_2HPO_4Aq, decomposing by HClAq, and dissolving the acids thus formed in ether. The phosphotungstic acids are unchanged in solutions in dilute acids; these solutions are scarcely acted on by H_2S, and very slightly by zinc; they give phosphates and tungstates when boiled with alkalis; characteristic pps. are produced with alkaloids, urea, albumen, &c.

Phosphoduodecitungstic acid and salts $P_2O_5.24WO_3.xH_2O$ and $yMO.P_2O_5.24WO_3.xH_2O$. The acid is obtained by evaporating a solution of H_3PO_4 and $H_2W_4O_{13}.xH_2O$ in the proper proportion (Péchard, *l.c.*); by boiling a solution of tungstate and phosphate of Na, in the ratio $24Na_2WO_4:2Na_2HPO_4$, acidulating with HNO_3Aq, ppg. by $HgNO_3Aq$, decomposing the Hg salt by HClAq, filtering, and evaporating *in vacuo*

(Gibbs, *Am.* 2, 217); by boiling H_3PO_4Aq with $BaWO_4$ in the proper proportion, decomposing by a small excess of H_2SO_4Aq, removing H_2SO_4 by BaOAq, filtering, and evaporating (Sprenger, *J. pr.* [2] 22, 418). The acid crystallises in *white, regular octahedra, or cubes. The value for x in the formula* $P_2O_5.24WO_3.xH_2O$ *varies according to different observers, from 40 to 53,* 59, and 61. The salts $yMO.P_2O_5.24WO_3.xH_2O$ are obtained by mixing tungstates (normal or para- salts) with H_3PO_4Aq or a phosphate, and decomposing by slight excess of HClAq, HNO_3Aq, or H_2SO_4Aq; in most cases the salts ppt. as fine, white powders; in some cases it is advisable to evaporate to dryness, extract with alcohol and ether, and evaporate. The salts have been described by Gibbs (*l.c.*); Kehrmann (*Zeit. f. anorg. Chemie*, 1, 430); K. a. Freinkel (*B.* 24, 2327); Sprenger (*J. pr.* [2] 122, 418); and Brandhorst a. Kraut (*A.* 249, 373). Salts have been obtained wherein $MO = (NH_4)_2O$, BaO, CuO, K_2O, Ag_2O, and Na_2O, and $y = 1$, 2, and 3.

Phospholuteotungstic acid and salts. $P_2O_5.16WO_3.xH_2O$ and $yMO.P_2O_5.16WO_3.xH_2O$. The acid is obtained by boiling Na_2WO_4Aq with H_3PO_4Aq, acidulating with HNO_3Aq, adding NH_4Cl and boiling, crystallising the pp. from NH_4ClAq, evaporating the NH_4 salt thus produced with *aqua regia*, and crystallising the acid so formed from water (for details *v.* K., *l.c.*). To an acid obtained by decomposing the K salt by H_2SiF_6Aq, or the Ag salt by HClAq, K. gives the formula $P_2O_5.18WO_3.xH_2O$; and he says that the salts are $yMO.P_2O_5.18WO_3.xH_2O$. The acid forms citron-yellow, six-sided tablets; it melts by the heat of the hand, and is very soluble in water. According to K. (*B.* 20, 1805; *A.* 245, 45), salts of this series are obtained by boiling any phosphotungstates with excess of H_3PO_4Aq in presence of an alkali salt. It is probable that two series of salts exist—one with $16WO_3$ and another with $18WO_3$ (*cf.* Gibbs, *l.c.*; and Péchard, *l.c.*). Salts have been obtained wherein $MO = (NH_4)_2O$, BaO, CaO, CuO, PbO, and K_2O, and $y = 1$, 3, 4, and 6.

Other phosphotungstic acids and salts.

I. Salts of the form $yMO.P_2O_5.22WO_3.xH_2O$ have been obtained, wherein $MO = (NH_4)_2O$, BaO, and K_2O, and $y = 2, 3, 4$, and 7 (*v.* K. a. F., *B.* 24, 2327; 25, 1966; K., *Zeit. f. anorg. Chemie*, 1, 435; Sprenger, *l.c.*; Gibbs, *l.c.*).

II. An acid of the form $P_2O_5.21WO_3.xH_2O$, and salts $yMO.P_2O_5.21WO_3.xH_2O$, where $MO = (NH_4)_2O$, K_2O, and Ag_2O and $y = 3$, have been isolated (K. a. F., *l.c.*; K., *l.c.*).

III. The acid $P_2O_5.20WO_3.xH_2O$ and a salt $6BaO.P_2O_5.20WO_3.xH_2O$ were obtained by Péchard (*l.c.*) and Gibbs (*l.c.*).

IV. For the acid $P_2O_5.12WO_3.xH_2O$ and the salts $yMO.P_2O_5.12WO_3.xH_2O$, where $MO = (NH_4)_2O$, BaO, CaO, CuO, PbO, Li_2O, MgO, Hg_2O, K_2O, Ag_2O, Na_2O, Tl_2O, and ZnO, *v.* Péchard (*C. R.* 110, 754).

V. A few salts of the form $yMO.P_2O_5.7WO_3.xH_2O$ have been obtained ($MO = (NH_4)_2O$, BaO, CaO, Hg_2O, Na_2O; y doubtful) (Gibbs, *l.c.*; K., *l.c.*).

VI. Compounds of alkali phosphates with WO_3, and with phosphoric acids and WO_3, have been isolated; also compounds of alkalis with H_3PO_3 and WO_3, and with H_3PO_2 and WO_3, are described by Gibbs (*Am.* 5, 361; 7, 313, 392).

PLATINITUNGSTATES, *v.* this vol., p. 283.

SILICOTUNGSTIC ACIDS AND SALTS. Three compounds *of* SiO_2 *with* WO_3 *and* H_2O*, which react as acids, have been isolated, and many compounds* of bases with SiO_2 and WO_3 have been obtained (Marignac, *A. Ch.* [4] 3, 5).

Silicoduodecitungstic acid, and salts $SiO_2.12WO_3.xH_2O$; as most of the salts contain $4M_2O$ (or 2MO) the acid is usually written $4H_2O.SiO_2.12WO_3.xH_2O$ ($= H_8SiW_{12}O_{42}.xH_2O$). According to Drechsel (*B.* 20, 1452), the acid is most easily obtained by dissolving Na_2WO_4 in boiling water, nearly neutralising with HNO_3Aq, dissolving the crystals that separate in cold water, boiling this solution with gelatinous $SiO_2.xH_2O$ until HClAq ceases to give a pp., filtering, evaporating, adding a large excess of H_2SO_4Aq, extracting with ether, separating the lowest layer and evaporating (for details *v.* D., *l.c.*). Large, colourless, dimetric octahedra (with $x = 29$); loses $25H_2O$ at 100°, and all H_2O at 350°. Very soluble in water and alkali solutions. Most of the salts of this acid have the composition $4M_2O.SiO_2 12WO_3.xH_2O$, or $2MO.SiO_2.12WO_3.xH_2O$; $M_2O = (NH_4)_2O$, Hg_2O, K_2O, Ag_2O, Na_2O; $MO = BaO$, CaO, MgO; x varies from 7 to 28 (Marignac, *l.c.*).

Tungstosilicic acid, and salts. This name is generally given to an acid containing SiO_2 and WO_3 in the same ratio (1:12) as silicoduodecitungstic acid. The formula of the acid is generally written $4H_2O.SiO_2.12WO_3.20H_2O$. The acid is obtained by evaporating a solution of silicodecitungstic acid to dryness, taking up with water, filtering from separated SiO_2, evaporating to a syrup, and allowing to crystallise. Forms short, white, triclinic prisms; melts under 100°, giving off $16H_2O$ and again solidifying. The salts of this acid are obtained by dissolving carbonates in a solution of the acid, and evaporating; they are more soluble and less easily crystallised than the salts of the duodeci- acid; the salts are of the forms

(1) $2MO(4M_2O).SiO_2.12WO_3.xH_2O$, where $M = Ca$, or $M_2 = K_2$;

(2) $2M_2O.2H_2O.SiO_2.12WO_3.xH_2O$, where $M_2 = K_2$ or Na_2; some more complex salts have also been isolated (Marignac, *l.c.*).

Silico-decitungstic acid, and salts. The acid $4H_2O.SiO_2.10WO_3.xH_2O$ (x probably $= 3$) is obtained by decomposing the Ag salt by HClAq, filtering, and evaporating *in vacuo*; the Ag salt is prepared by adding $AgNO_3Aq$ to the NH_4 salt which is obtained by boiling an acid tungstate of NH_4 with $SiO_2.xH_2O$, filtering, and evaporating. The acid forms a clear, yellowish, glassy solid, which does not wholly dissolve in water; loses $3H_2O$ at 100°; on boiling with water most of the SiO_2 separates, and the filtrate contains tungstosilicic acid. A few salts have been obtained; they are difficult to purify from silicotungstates and tungstosilicates (Marignac, *l.c.*).

STANNIPHOSPHOTUNGSTATES. Gibbs (*Am.* 7, 392) obtained the salt $2(NH_4)_2O.P_2O_5.2SnO_2.22WO_3.15H_2O$ by the reaction of $SnCl_4.2NH_4Cl$ and $2Na_2O.P_2O_5.24WO_3.xH_2O$.

TITANOTUNGSTIC ACIDS. Two acids, $H_2O.TiO_2.12WO_3.xH_2O$ and $H_2O.TiO_2.10WO_3.xH_2O$, are described by Lecarme (*v.* Klein, *Bl.* [2] 36, 17).

VANADOTUNGSTIC ACIDS AND SALTS. Several compounds of WO_3 with V_2O_5 and H_2O have been described by Gibbs (*Am.* 4, 377; 5, 361, 391) and Rosenheim (*A.* 251, 197); they belong to the forms $V_2O_5.10WO_3.xH_2O$, $V_2O_5.18WO_3.xH_2O$, and $V_2O_5.4WO_3.xH_2O$. Compounds of these with yM_2O and yMO are also described; and a great variety of compounds coming under the general formula $mMO.nV_2O_5.pWO_3.xH_2O$ have been obtained (*cf.* Friedheim, *B.* 23, 1505; and Rothenbach, *B.* 23, 3050).

Tungsten, oxybromides of. Two oxybromides, WO_2Br_2 and $WOBr_4$, are formed by the reaction of Br on WO_2, and in other ways. The formula $WOBr_4$ is very probably molecular, from the analogy of $WOCl_4$.

TUNGSTEN DIOXYDIBROMIDE WO_2Br_2. Obtained by heating WO_2 in a stream of Br vapour, also by passing vapour of WBr_5 over heated WO_2 (Roscoe, *C. N.* 25, 73); also by heating WS_2 or a mixture of WO_3 and C in Br (Borck, *J. pr.* 54, 254). Red, transparent, prismatic crystals; appearing black when hot, and giving a yellow powder. Volatilised at red heat with partial decomposition to WO_3 and $WOBr_4$.

TUNGSTEN OXYTETRABROMIDE $WOBr_4$. Obtained by passing Br vapour over a heated mixture of equal parts of WO_3 and W, and cautiously distilling from less volatile WO_2Br_2 (Roscoe, *C. N.* 25, 73). Also formed by passing Br mixed with some O over heated W, or by heating a mixture of WO_3 and C in Br vapour (Blomstrand, *J. pr.* 82, 430). Brownish black, lustrous, crystalline needles; melts at 277° and boils at 27°. Heated in moist air gives WO_3 and HBr, and is decomposed to the same products by water.

Tungsten, oxychlorides of. Two oxychlorides, WO_2Cl_2 and $WOCl_4$, are formed by heating W in Cl mixed with some O, and in other reactions.

TUNGSTEN DIOXYDICHLORIDE WO_2Cl_2. Obtained by heating WO_2 in a stream of Cl, and subliming (Roscoe, *C. N.* 25, 63); also by passing CO_2 over a mixture of WO_3 and $CaCl_2$ heated to redness (Schultze, *J. pr.* [2] 21, 430). Also formed, along with $WOCl_4$, by heating W in Cl mixed with O; by heating WO_3 and C in Cl; by heating WO_3 in CCl_4 (Watts a. Bell, *C. J.* 33, 442); and by heating WO_3 with PCl_5 (Schiff, *A.* 197, 185; *cf.* TUNGSTEN TRIOXIDE, *Reactions*, No. 10, p. 801). Yellow, four-sided tablets; sublimes without melting at c. 266°, with partial decomposition to WO_3 and $WOCl_4$. Not decomposed in moist air, nor by cold water (R., *l.c.*). Heated in dry NH_3 gives off NH_4Cl and leaves WO_2 (Rideal, *C. J.* 55, 43); in this reaction WO_2Cl_2 behaves like CrO_2Cl_2 (R., *C. J.* 49, 367). According to Smith a. Shinn (*Zeit. f. anorg. Chemie*, 4, 381), a black compound $W_4O_4N_4H_2$ is formed by heating WO_2Cl_2 in dry NH_3.

TUNGSTEN OXYTETRACHLORIDE $WOCl_4$. Mol. w. 341·04. Formed by heating W in Cl containing a little O; also by passing Cl over a hot mixture of WO_3 and C; by heating WO_3 in CCl_4 (Watts a. Bell, *C. J.* 33, 442); by heating WCl_5 or WCl_6 in O and Cl; by heating WCl_6 with $H_2C_2O_4$; and by heating WO_2Cl_2. Prepared by passing vapour of WCl_6 over heated WO_3 in a current of Cl (Roscoe, *C. N.* 25, 63). Also by heating WO_3 and PCl_5, in the ratio WO_3:PCl_5 or WO_3:$2PCl_5$, distilling off $POCl_3$ and the small quantities of WCl_5 and WCl_6 that are formed, washing the reddish residue with a little cold CS_2 (to remove WCl_6), then dissolving in a larger quantity of warm CS_2, evaporating, and carefully heating the residue in a stream of CO_2, whereby the more volatile $WOCl_4$ is separated from WO_2Cl_2 (Schiff, *A.* 197, 185).

$WOCl_4$ forms ruby-red, transparent needles; melts at 210·4°, and volatilises at 227·5°, forming a yellow vapour (R., *l.c.*). V.D. 170·2 to 175·8 at 350°, 171·5 at 440° (R., *l.c.*; *cf.* Debray, *C. R.* 60, 820). Exposure to air produces a crust of yellow WO_2Cl_2. Heated in NH_3 probably gives W_2N_3 (Rideal, *C. J.* 55, 43). Decomposed by water, with a hissing sound, to WO_3 and HClAq (Roscoe, *l.c.*).

Tungsten, oxyfluorides of. No compound of W with O and F has been isolated, but compounds are known which may be regarded as containing WO_2F_2. These compounds, $WO_2F_2.2MF$ and $WO_2F_2.MF$, and also a compound $WO_3F_2.2KF$, are described under TUNGSTOXYFLUORIDES (p. 799).

Tungsten, phosphides of. By heating W in vapour of P, a dark-grey powder was obtained by Wöhler a. Wright (*A.* 79, 244), to which they gave the composition W_3P_4. By heating a mixture of WO_3 and P_2O_5 in a graphite crucible, W. a. W. (*l.c.*) obtained large, dark-grey, lustrous, six-sided prisms; S.G. 5·207; insoluble in acids, including *aqua regia*, soluble in a molten mixture of Na_2CO_3 and $NaNO_3$; unchanged by heating in air, but burns brilliantly in O. From an estimation of the P, W. a. W. gave the formula W_2P.

Tungsten, salts of. No salts have been isolated by replacing the H of oxyacids by W. Except the halides, the only salts of W that are known are those wherein W forms part of the negative radicle.

Tungsten, selenides of. By saturating a solution of $Na_2W_4O_{13}$ with H_2Se, and then adding dilute H_2SO_4Aq, Uelsmann (*A.* 116, 125) obtained a black pp., to which he gave the formula WSe_3 (one estimation of W is given); by heating this in a tube a grey solid was obtained, said by U. to be WSe_2 (no analyses). WSe_3 is said to be easily soluble in solutions of alkalis, alkali sulphides, or alkali selenides.

Tungsten, sulphides of. Two compounds of W and S are known, WS_2 and WS_3; the latter is acidic, forming salts M_2WS_4. The V.D. of neither has been determined.

TUNGSTEN DISULPHIDE WS_2. Obtained by heating WO_3 to whiteness in vapour of S or in H_2S (Berzelius); also by heating W and S; also by heating WO_3 with 6 pts. HgS out of contact with air (Borck, *J. pr.* 54, 254). According to Carnot (*Bl.* [2] 32, 164), WS_2 is usually formed when a compound of W is heated in a stream of dry H_2S (*v.* also von Uslar, *A.* 94, 256; Corleis, *A.* 232, 262). A dark-grey, graphite-like, lustrous, crystalline powder (*v.* Riche, *A. Ch.* [3] 50, 26). Is said to decompose steam at a full red heat; reduced to W by very long continued heating in H.

Tungsten trisulphide WS_3. *Obtained by fusing powdered wolframite with ·2 pts. C, 3 pts. S, and 3 pts.* Na_2CO_3, dissolving in water, decomposing the Na_2WS_4Aq thus produced by HClAq, washing the pp. completely out of contact with O, and drying at 100° (von Uslar, *A.* 94, 256; Corleis, *A.* 232, 264). A black powder; slightly soluble in water, more soluble on boiling, probably with partial decomposition. Soluble in alkali sulphide solutions, forming thio- salts (*v.* Tungsten, thio- acids and salts of, *infra*). By adding to Na_2WS_4Aq a little more HClAq than was needed to combine with the Na, Winssinger (*Bl.* [2] 49, 452) obtained a colloidal form of WS_3.

Tungsten, sulpho- acids and salts of, *v.* next article.

Tungsten, thio- acids and salts of. By saturating $(NH_4)_2WO_4Aq$ and K_2WO_4Aq with H_2S, Berzelius obtained $(NH_4)_2WS_4$ and K_2WS_4 (*P.* 8, 267); these salts were more fully examined by Corleis (*A.* 232, 258), who also obtained Na_2WS_4, and also some thio-oxy-tungstates. All the thio-tungstates that have been isolated are ortho- salts, *i.e.* salts of H_2WS_4. Very dilute solutions of thiotungstates can be titrated with IAq in presence of $KHCO_3$ (C., *l.c.*).

Ammonium thiotungstate $(NH_4)_2WS_4$. Obtained by passing H_2S for four or five hours into a solution of 10 g. $WO_3.H_2O$ in 100 c.c. NH_3Aq S.G. ·94, + 20 c.c. water, allowing to stand for some hours in a closed vessel, and washing the crystals that separate with alcohol and ether. Forms orange-yellow prisms, isomorphous with $(NH_4)_2MoS_4$; very easily decomposed in moist air; easily soluble in water, slightly soluble in alcohol. Heated in CO_2 gives WS_2 (B., *l.c.*; C., *l.c.*).

Ammonium dithio-oxy-tungstate $(NH_4)_2WS_2O_2$. Obtained by passing H_2S into a solution of 10 g. $WO_3.H_2O$ in 40 c.c. NH_3Aq S.G. ·90, + 10 c.c. water, until the liquid becomes turbid, and washing the crystals that form with alcohol and ether. Forms yellow, prismatic crystals. When dry, the salt is unchanged in air. Decomposed by re-crystallising from water, giving paratungstate $(NH_4)_6W_7O_{24}.6H_2O$ (C., *l.c.*).

Potassium thiotungstate K_2WS_4. Obtained by warming $(NH_4)_2WS_4$ with KHSAq, adding alcohol, and crystallising from conc. KHSAq. Forms yellow, prismatic needles; easily soluble in water. By continued boiling with KHSAq paratungstate is formed, $K_6W_7O_{24}.6H_2O$ (C., *l.c.*). Forms a *double salt* with KNO_3, with the composition $K_2WS_4.KNO_3$ (B., *l.c.*).

Potassium trithio-oxy-tungstate $K_2WS_3O.H_2O$. Obtained in citron-yellow, quadratic tablets, by passing H_2S for three or four hours into a solution of 10 g. K_2WO_4 in 10 c.c. water, and evaporating *in vacuo*, or precipitating by alcohol (C., *l.c.*).

Potassium monothio-oxy-tungstate $K_2WSO_3.H_2O$. Obtained, in almost colourless, very hygroscopic, crystalline masses, by passing H_2S into a solution of 10 g. K_2WO_4 in 5 c.c. water until the liquid is turbid, filtering, adding 4 to 5 vols. alcohol, separating the under layer of liquid, allowing to crystallise, and washing with alcohol and ether (C., *l.c.*).

Sodium thiotungstate Na_2WS_4. Obtained, *but not pure, by Corleis (l.c.), by decomposing* $(NH_4)_2WS_4$ *by NaHSAq.*

Tungsten, thiochloride of. By heating W to redness with S_2Cl_2, Smith a. Oberholtzer (*Zeit. f. anorg. Chemie*, 5, 63) obtained a red, crystalline sublimate, unstable in air, probably $W_2S_7Cl_4$.

TUNGSTEN BRONZES *v.* under Tungsten oxyacids, p. 806.

TUNGSTIC ACIDS *v.* Tungsten oxyacids, p. 802; also Tungsten thio-acids, *supra*.

TUNGSTOXYFLUORIDES *v.* under Tungsten fluorides, p. 799.

TUNGSTEN, ORGANIC COMPOUNDS OF. Tungsten, heated with MeI at 240°, forms WMe_4I_2 [110°], which crystallises in tables, and is converted by Ag_2O into WMe_4O, which dissolves in acids (Riche, *C. R.* 42, 203; Cahours, *A.* 122, 70).

TUNICIN *v.* Animal cellulose, vol. i. p. 718.

TURMERIC. The root of *Amomum Curcuma*. It contains curcumin (*q. v.*) and turmerol.

TURMERIC ACID $C_{11}H_{14}O_2$. [35°]. A product of oxidation of turmerol by cold $KMnO_4$ (Jackson a. Menke, *Am.* 6, 77). Needles, sl. sol. water, v. sol. alcohol.—CaA'_2 3aq. S. (of CaA'_2) 1·28 at 16°. White needles.—AgA'.

TURMEROL $C_{19}H_{28}O$ (?). (193°–198° at 60 mm.). S.G. ^{17} ·902. $[\alpha]_D = 33·5°$. An oil occurring in turmeric. Distils with decomposition at 285°–290° (Jackson a. Menke, *Am.* 4, 368; 6, 77). Dextrorotatory. Does not combine with $NaHSO_3$. $KMnO_4$ oxidises it to acetic, terephthalic, turmeric, and apoturmeric acids. PCl_5 forms $C_{19}H_{27}Cl$, which is also got by heating turmerol with conc. HClAq at 150°. Sodium forms $C_{19}H_{27}ONa$, whence isobutyl iodide forms oily $C_{19}H_{27}OC_4H_9$.

Apoturmeric acid $C_8H_8(CO_2H)_2$ (?). [221°]. Woolly mass, sol. boiling water.

TURPENTINE. Semi-fluid resins exuding from coniferous trees. They consist of resin dissolved in oil of turpentine. On distillation oil of turpentine passes over and colophony remains behind. The various oils of turpentine are described under Terpenes. The chief constituent of colophony is abietic anhydride (*v.* Abietic acid and Sylvic acid). On oxidation by dilute HNO_3 colophony yields isophthalic, trimellitic, and terebic acids (Schreder, *A.* 172, 93). On the products of distillation of colophony *v.* Resins.

TURPETHIN $C_{34}H_{56}O_{16}$. [c. 183°]. Occurs in the root of *Convolvulus Turpethum* (*Ipomœa Turpethum*) (Boutron-Charlard, *J. Ph.* 8, 131; Spirgatis, *J. pr.* 92, 97; *A.* 139, 41). Purgative yellowish-brown resin, v. sol. alcohol, insol. ether (difference from jalapin). Conc. H_2SO_4 forms a red solution. Boiling alkalis convert it into turpethic acid. Boiling dilute mineral acids yield glucose (3 mols.) and turpetholic acid (1 mol.).

Turpethic acid $C_{34}H_{60}O_{18}$. Amorphous yellowish mass, v. sol. water. Split up by boiling HClAq into glucose and turpetholic acid.—BaA''.—$BaH_2A''_2$ (dried at 100°).

Turpetholic acid $C_{16}H_{32}O_4$. [c. 88°]. Minute needles (from dilute alcohol), sl. sol. ether.—NaA' (dried at 100°).—BaA'_2. Amorphous.—AgA'. Amorphous pp.

Ethyl ether EtA'. [72°]. Plates.

TYLOPHORINE. An alkaloid in *Tylophora asthmatica* (Hooper, *Ph.* [3] 21, 617). Crystalline, sl. sol. water, sol. alcohol and ether.

TYPE METAL. An alloy of 15–20 parts Sb with c. 70 parts Pb, and 10 to 15 parts Sn; *v.* Lead alloys, vol. iii. p. 124.

TYPES. The object of classification is to put together like things, and to put apart things that are unlike. A perfect system of chemical classification would place side by side those elements and compounds that are chemically similar, and it would also indicate the relations that exist between all the elements and all the compounds. Inasmuch as the object of chemistry is the study of the connections between composition and properties, and between changes of composition and changes of properties, a complete scheme of chemical classification must indicate the relations of the substances classified, both as regards composition and also as regards properties. To connect composition with properties necessitates a thorough knowledge of both, and this knowledge can be gained only by comparing one substance with other substances. But, because of the large amount of detailed investigation that is required before the chemical properties of an element or a compound are known, chemists have often forgotten the larger issues of their labours, and have busied themselves rather with the examination of individual bodies than with the comparative study of many bodies. And, because of the imperfection of chemical knowledge at any time, those who have attempted the classification of chemical substances have generally paid chief attention either to the composition or to the properties of the substances to be classified. Hence systems of classification have sometimes prevailed that were founded chiefly on similarities of composition, and at other times classificatory schemes have been in vogue that rested mainly on similarities of properties. But there has always been a desire, and generally an effort, to classify on the bases of composition and properties. To classify satisfactorily demands the recognition of a simple class-mark, which shall also be clear, definable, and invariably applicable. It is probably correct to say that none of the larger classes of chemical compounds has a class-mark of this description. Hence the main difficulty in chemical classification. Take, for instance, the great class of acids. What is the class-mark? What must be known about the composition of a compound before it is put into the class of acids? There is no single and sufficient class-mark to be gained by studying the compositions of acids. What, then, about the properties of acids? Here, too, no simple, definable, and applicable property has been found which serves to distinguish acids from all other compounds. Acids, it is usually said, are compounds containing *replaceable hydrogen.* But the expression replaceable hydrogen has not been, and cannot be, exactly defined. Hence, all that can be done is to set up an ideal or typical acid, and to place in the class *acids* those compounds which fairly closely approach this type as regards both properties and composition. And as with acids so with other classes of compounds. A classification by means of types becomes inevitable in such a science as chemistry, but a typical classification cannot be final in any exact science.

Lavoisier's system of classification rested on oxygen; compounds were regarded as formed by the union of oxygen with other elements or groups of elements; the non-oxygenated part of a compound was called by Lavoisier the *rest* or *radicle*; compounds of oxygen with certain radicles were bases, compounds with other radicles were acids, and salts were formed by the union of bases with acids. Lavoisier used the term *radicle* to include elements and groups of elements.

'J'ai déjà fait observer, que dans le règne minéral presque tous les radicaux oxidables et acidifiables etaient simples; que dans le règne végétal au contraire, et surtout dans le règne animal, il n'en existait presque pas qui ne fussent composés au moins de deux substances, d'hydrogène et de carbone; que souvent l'azote et le phosphore s'y réunissaient, et qu'il en résultait des radicaux à quatre bases.'—*Traité élémentaire de Chimie*, [1793], p. 251.

About twenty-four years after Lavoisier made this statement Berzelius repeated it.

'Nachdem wir den Unterschied zwischen den Producten der organischen und der unorganischen Natur, und die verschiedene Art und Weise wie ihre entfernteren Bestandtheile untereinander verbunden sind, näher kennen gelernt, haben wir gefunden, dass dieser Unterschied eigentlich darin besteht, dass in der unorganischen Natur alle oxydirten Körper *ein einfaches Radical haben*, während dagegen alle organischen Substanzen aus *Oxyden mit zusammengesetztem Radical* bestehen.'—*Lehrbuch der Chemie*, 2 Aufl. [Stockholm, 1817], vol. i. p. 544.

Why do acids and bases unite to form salts? What is the cause of the formation of compounds by the union of radicles, either simple or compound? These questions were answered by Berzelius by appealing to the fact that the electric current very often resolves compounds into two parts, and in many cases also effects the combination of elements or groups of elements. Radicles combine, said Berzelius, because the negative electricity on one is thereby neutralised by the positive electricity on the other. Thus arose the electro-chemical conception of dualism (*v.* Dualism, vol. ii. p. 415; *cf.* Radicle, vol. iv. p. 393).

In 1832 Liebig and Wöhler made an exhaustive study of compounds obtained from bitter-almond oil; they showed that the relations of composition and properties of these compounds were brought together, and expressed in a consistent conception by supposing that all the compounds contained a radicle having the composition C_7H_5O($C = 12$, $O = 16$); this group of elements, common to all the derivatives of bitter-almond oil, they called *benzoyl*. The work of Liebig and Wöhler marked a great advance in chemical classification; it was the actual working out of the connections between composition and properties of a number of compounds, and the expression of these connections in clear and definite language. The term *radicle* became henceforth the expression of a vivifying conception. The compounds derived from bitter-almond oil had certain common properties, and they had also a common composition; they belonged to the same type. The compounds of benzoyl examined by Liebig and Wöhler included such compounds as these: $C_7H_5O.OH$, $C_7H_5O.H$, $C_7H_5O.Cl$, $C_7H_5O.CN$, $C_7H_5O.NO_2$. The radicle C_7H_5O is common to all; this radicle is united with H, Cl, NO_2, CN, or some other radicle, in the different compounds; nevertheless, the properties of the compounds are so similar that all are said to belong to one type. To what extent, then, it was asked, may the properties of one radicle differ from those of another before the replacement of one of these by the other carries with it a change of type? The answer generally given to this question was: If the replacing radicle is chemically similar to the radicle replaced the type will not be destroyed. In 1834 Dumas, from the study of the action of chlorine on various organic compounds, announced the *empirical laws of substitution* as follows: (1) When a compound containing hydrogen is subjected to the dehydrogenating action of chlorine, bromine, iodine, oxygen, &c., one atom of chlorine, bromine, iodine, or oxygen, is taken up for each atom of hydrogen lost by the compound. (2) The same rule applies, without modifications, when the compound contains oxygen. (3) If a hydrogenised compound contains water the hydrogen of the water is given up without replacement, and then another quantity of hydrogen is absorbed, so that the final result is a replacement of hydrogen. A year or so later Laurent propounded a *theory of substitution*, which asserted that when equivalent substitution of hydrogen by chlorine or bromine occurs the chlorine or bromine takes the place of the hydrogen, and to a certain extent plays the same part as the hydrogen, and hence the chlorinated or brominated product must be similar to the compound from which it has been prepared. Laurent's views were much opposed, for a time by Dumas himself; but they gradually prevailed, and chemists became familiarised with the notion of the replacement of such a decidedly electro-positive element as hydrogen by an element so decidedly electro-negative as chlorine, resulting in the production of a compound of the same chemical type as the original substance.

About 1839 Dumas sought to distinguish mechanical types from chemical types. Compounds formed one from the other by the replacement of a certain number of equivalents of one radicle by the same number of equivalents of another radicle, and having their radicles similarly combined, and exhibiting similar properties, were said to belong to the same *chemical type*. Compounds were said to belong to the same *mechanical type* when they were composed of equal numbers of equivalents of radicles, but differed essentially in their properties. Dumas at this time regarded the properties of compounds as conditioned more by the arrangement than by the nature of their parts. He compared compounds to planetary systems, the planets being represented by the atoms of the compounds. One atom, he said, might be replaced by another atom, or an atom by a group of atoms, without destroying the system; if the number of replacing atoms, or radicles, were the same as the number of atoms, or radicles, replaced, and the relative arrangement of all the atoms or radicles were not altered, the compounds belonged to the same type. By some such development as this the theory of types came to include the older theory of radicles.

It is evident that the terms used by Dumas and others to express the conceptions of the theory of types are vague and incapable of exact definition. The expression 'equivalent radicles' cannot be defined, nor can an exact and invariable connotation be given to the expressions 'radicles similarly combined' and 'compounds having similar properties.' But if it had been possible to classify chemical substances in an ideally perfect way the theory of types would not have arisen. If there is to be a typical classification the language whereby that classification is expressed must be more or less vague. Whether a compound formed from another by replacing equivalents of one kind by an equal number of equivalents of another kind does or does not belong to the same type as the parent compound can be determined only by a careful study of the properties of both compounds and by a comparison of the compounds one with another. The application of the theory of types was possible only when the properties and the compositions of compounds were exhaustively compared. The theory of types produced much fruit, because it suggested and demanded much inquiry into the fundamental problem of chemistry.

In 1849 Wurtz prepared two compounds which resembled ammonia in their prominent characters. These compounds were found to have the compositions C_2H_5N and C_4H_7N respectively (C = 6). The similarities between the properties of these compounds and ammonia led Wurtz to regard them as *substituted ammonias*, and to express this conception by the formulæ $C_2H_3.NH_2$ and $C_4H_5.NH_2$. One method by which these compounds were prepared consisted in treating methyl and ethyl bromides (C_2H_3Br and C_4H_5Br; C = 6) with ammonia, and then decomposing the products by potash. These reactions suggested the view that the new compounds were derived from methylic and ethylic ethers (C_2H_3O and C_4H_5O, according to the notation then used) by substituting NH_2 for O. Both views agreed in representing the new compounds as $C_2H_3.NH_2$ and $C_4H_5.NH_2$ respectively. But the properties of the compounds resembled those of ammonia; hence the view that Wurtz's compounds were derived from ammonia prevailed. This view was expressed by saying that these compounds belonged to the ammonia type, and by comparing the formula of the typical compound with the formulæ of the compounds formed after that exemplar; thus:

Type:	*Derivatives:*
Ammonia $NH_2.H$.	Methylamine $NH_2.C_2H_3$.
	Ethylamine $NH_2.C_4H_5$.

Very soon after Wurtz's preparation of methylamine and ethylamine Hofmann argued that it should be possible to substitute each of the three atoms of hydrogen in NH_3 by the radicles C_2H_3 and C_4H_5, and so to obtain the compounds $NH(C_2H_3)_2$, $N(C_2H_3)_3$, $NH(C_4H_5)_2$, and $N(C_4H_5)_3$ (C = 6), all which compounds ought to resemble ammonia in their properties. Hofmann fulfilled his own prophecy by preparing di- and tri-methylamine and di- and tri-ethylamine; and, basing his methods on the conception of the ammonia type, he prepared a large series of ammonia-like compounds derived from NH_3, $2NH_3$, &c., by substituting for H various radicles composed of carbon and hydrogen. The *ammonia type* was thus established.

About the year 1850 Williamson studied the relations of ether to alcohol. The formula of ether was then written C_4H_5O (C = 6, O = 8), and that of alcohol $C_4H_6O_2$. Williamson heated potassium alcoholate ($C_4H_5KO_2$) with ethylic iodide (C_4H_5I), expecting to obtain ethylated alcohol ($C_4H_5(C_4H_5)O_2$); but he obtained common ether. Williamson suggested that the formula then accepted for ether should be doubled, and written $(C_4H_5)_2O_2$. He also found that by heating common alcohol with sulphuric acid, and adding methylic alcohol to the hot mixture, an ether-like compound was obtained, the simplest formula of which was C_3H_4O (C = 6, O = 8). Williamson argued that if common ether is C_4H_5O, then the ether of methylic alcohol must be C_2H_3O, and that, in the reaction of sulphuric acid with ethylic and methylic alcohols simultaneously, a mixture of these two ethers might be expected to be produced. To account for the facts he had observed Williamson proposed to double the formulæ of the two ethers and to write them $(C_4H_5)_2O_2$ and $(C_2H_3)_2O_2$; and for the formula of the ether formed by the action of sulphuric acid on the two alcohols simultaneously he proposed the formula $C_4H_5(C_2H_3)O_2$ [$= 2C_3H_4O$]. Williamson compared the relations between the alcohols and ethers with the relations between water, potash, and potassium oxide. These relations are made clearer if the formulæ are expressed in terms of the atomic weights C = 12 and O = 16; thus:

Type:	*Derivatives:*
Water $H.H.O$	Alcohol $C_2H_5.H.O$
	Ether $C_2H_5.C_2H_5.O$
	Potash $K.H.O$
	Potassium oxide $K.K.O$.

Thus arose the *water type*. To this were referred such compounds as acetic acid $C_2H_3O.H.O$, anhydrous acetic acid $C_2H_3O.C_2H_3O.O$, and many others.

Gradually the greater number of compounds, both organic and inorganic, came to be referred to four fundamental types—the *hydrochloric acid type* HCl, the *water type* HHO, the *ammonia type* NHHH, and the *marsh gas type* CHHHH. To these were added so-called *condensed types* and *mixed types*; sulphuric acid, for instance, $SO_2.OH.OH$, was said to belong to the *double water type*.

$$\text{Thus:}\quad \begin{matrix}\left.\begin{matrix}H\\H\end{matrix}\right\}O\\ \left.\begin{matrix}H\\H\end{matrix}\right\}O\end{matrix}\ \text{gives}\ SO_2\begin{matrix}\left.\begin{matrix}H\\ \end{matrix}\right\}O\\ \left.\begin{matrix} \\H\end{matrix}\right\}O\end{matrix}$$

Oxamic acid $CO.NH_2.CO.OH$ was regarded by Wurtz as derived from the *water-ammonia type*.

$$\text{Thus:}\quad \begin{matrix}\left.\begin{matrix}H\\H\end{matrix}\right\}O\\ \left.\begin{matrix}H\\H\\H\end{matrix}\right\}N\end{matrix}\ \text{gives}\ \begin{matrix}\left.\begin{matrix}H\end{matrix}\right\}O\\ \left.\begin{matrix}C_2O_2\\H\\H\end{matrix}\right\}N\end{matrix}$$

The great danger attending the development of the theory of types was, that careful investigations into the reactions of compounds might easily be abandoned in favour of a superficial examination of a compound, followed by a relegation of it to this or that type. The theory began by being very vague and elastic; the adoption of a few definite types rendered it more exact; but the temptation to manipulate formulæ on paper, and to invent condensed types and mixed types, gradually led chemists to see that the theory had done its work, and that it must give place to wider views, which should also be more accurate, regarding the connections between composition and properties.

The conception of types carried with it, from the first, more or less vague notions regarding the arrangements of the atoms in those collocations of atoms that form the reacting units of compounds; at any rate, this conception was bound up with the general conception of atomic arrangement. The reacting units of compounds that showed similar properties were thought of as composed of atoms similarly arranged. Moreover, the type was said to be maintained when an atom, or a group of atoms, in the parent compound was replaced by an equivalent number of atoms, or groups of atoms. These two conceptions, that of equivalency, and that of atomic arrangement, led gradually to the representation of the reacting unit, or molecule, of a compound as a definitely arranged group of atoms held together by actions and reactions between individual atoms; these conceptions led to the wider conception of valency, and to a system of classification based on the notion that each kind of atom is capable of directly combining with a limited, and determinable, number of other atoms. The formula given to chlorosulphonic acid, with the object of connecting the composition with the properties of this compound, and of suggesting relations between this and other compounds, may be taken as an example of the merging of the notion of types into that of valency. This acid was regarded as derived both from water and hydrochloric acid; it was supposed to belong to the mixed *water-hydrochloric acid type*. Hence the formula, $ClSO_3H$, was written thus:—

$$\textit{Type}\ \begin{matrix}HCl\\H\\HO\end{matrix}\qquad \textit{Chlorosulphonic acid}\ \left.\begin{matrix}Cl\\ \\HO\end{matrix}\right\}SO_2$$

The radicle SO_2 was regarded as equivalent to 2H; and it was said that the residues of the two parts of the mixed type, *i.e.* Cl and OH, were bound together by the radicle SO_2. Again, monochlorhydrin, $C_3H_7ClO_2$, was regarded as a derivative of the triple type HHO.HCl.HHO, and was said to be formed by the binding together of the three residues OH, Cl, OH by the radicle C_3H_5 regarded as equivalent to 3H. Thus:—

$$\textit{Type}\ \begin{matrix}HO\\H\\HCl\\H\\HO\end{matrix}\qquad \textit{Monochlorhydrin}\ \left.\begin{matrix}HO\\Cl\\HO\end{matrix}\right\}C_3H_5$$

The moment the conceptions underlying these formulæ, and formulæ like these, were expressed in the language of atoms and molecules, the notion of atomic valencies was gained. The group of atoms SO_2 replaces two atoms of hydrogen, one atom in the molecule HCl and one atom in the molecule HHO; and as the atomic group SO_2 is capable of directly combining with two atoms of hydrogen, or such a number of atoms as is equivalent to two atoms of hydrogen, this group binds together the atom Cl and the atomic group OH, and so the new molecule

$SO_2.OH.Cl$ is produced. This statement contains the fundamental conception of atomic valency; it also contains the conception of types, and that of radicles.

The radicles were compared as regards their equivalency, generally in terms of hydrogen; then the elementary atoms were compared, and arranged in classes, such that all in one class were exchangeable, any number of one kind for the same number of another kind.

When the atoms had been classified in accordance with the number of atoms of hydrogen, or atoms equivalent thereto, with which each was capable of combining, the foundations had been laid of a system of classification which was more accurate than that based on the notion of types, and which at the same time included the essential characters of the typical system. The article CLASSIFICATION in the first edition of this *Dictionary* represents the stage which had then (1863) been reached in the process of fusion of the theories of radicles, types, and valency. The system of classification developed in that article is based (1) on the compositions of compounds interpreted by help of the theory of valency, and (2) on the properties of the compounds interpreted by the help of the theory of types; the study of the properties of a compound is used to determine the radicles that the compound contains, and a knowledge of the valencies of these radicles determines the form of the compound, and, taken along with the reactions of the compound, the type to which it is to be referred.

Although the introduction of the principle of atomic equivalency widened the conception of chemical types, it also tended towards a method of classification which was based on too slight a study of the bodies to be classified. A superficial examination of a compound generally sufficed to bring out some similarities between it and a well-known typical substance; the new compound was at once referred to its type; the form of the type determined the form of the compound under examination; it was then only necessary to manipulate the empirical formula by arranging the elements in groups, or radicles, and to assign to each radicle such a valency as satisfied the general rules that had been deduced from the study of a few typical compounds. The conception of types became very mechanical in its applications, so mechanical indeed that it was in danger of becoming metaphysical. New radicles were easily invented, and their valencies were deduced by *a priori* arguments. Kekulé recalled chemists to the study of properties by insisting that the properties of a compound are conditioned by the properties of the atoms which compose the molecule of the compound; and at a later date Mendeléeff made the same demand by asserting that the properties and the compositions of all compounds are periodic functions of the atomic weights of the elements.

The notion of types plays an important part in the classification of elements and compounds that has arisen from the practical examination of the meaning of Mendeléeff's periodic law. The periodic classification of the elements lays considerable stress on the study of the typical oxides, hydrides, hydroxides, &c., of each group of elements; for instance, the highest salt-forming oxide of Group I. belongs to the type R_2O, that of Group II. to the type R_2O_2, and so on. But the word *type* is not used here with quite the same connotation as was given to it by the theory of types. All that is implied in statements such as those just made is, that the elements of Group I. combine with oxygen in the ratio of two atoms of element to a single atom of oxygen, that these oxides are salt-forming, and that they are characteristic of the elements of this group. The typical oxide-form of each group expresses the composition of that oxide which contains the greatest number of atoms of oxygen relatively to one atom of the group-element, and which oxide reacts either with acids or with alkalis to form corresponding salts. The oxides that belong to the typical oxide-form of a group may be acidic or basic, or some of them may be acidic and some basic; all that is asserted of their properties is that they are salt-forming. The properties of the typical oxide of any individual element are conditioned by the general character of the group, and the general character of the series, wherein the element is placed; by the special character of the element itself; and by the position of the element in the whole periodic system of classification. The term *type* is used in the nomenclature arising from the comparative study of the elements and compounds based on the periodic law with a wider, and at the same time a more exact, meaning than that which was given to it when the notion of types was made the basis of chemical classification. In the older classification the conception of types was the basis of the system; the conception was of necessity vague, and hence it was necessary sometimes to widen, and sometimes to narrow, the application of the conception. The modern system of classification is based on the relative weights of the atoms of the elements, and the conception of types plays a subsidiary part; the form of the typical oxide, or hydroxide, or other compound, is determined, as the compositions of all the compounds are determined, by the relative masses of the atoms of the elements; and the general character of the typical oxide, hydroxide, &c., of each group is determined, as the special character of each compound of each element is determined, also by the relative masses of the atoms of the elements.

The periodic classification of the elements and compounds makes use of the notion of types in another way, by applying the conception to certain elements. The elements placed in series 1 and 2, viz. H, Li, Be, B, C, N, O, and F, exhibit almost the whole range of properties of all the elements. The properties of the succeeding elements may almost be said to be but variations on the theme announced in the change from hydrogen to fluorine. These eight elements are types of all the others. In a somewhat narrower sense the element lithium summarises the range of properties shown in Group I.; beryllium summarises the range of properties shown in Group II.; boron, the properties of Group III.; carbon, the properties of Group IV.; nitrogen, the properties of Group V.; oxygen, the properties of Group VI.; and fluorine, the properties of Group VII. Each of the seven elements is the typical element of its group. Objections have been raised to this use of the term *typical*, on the ground that each of the elements in question differs more from any member of its group than any other two members of the group differ from one another. But if an element is to summarise the properties of some ten or eleven other elements, it must differ considerably from each of these, while at the same time it resembles them all. The question of typical elements, and also that of typical oxide-forms, &c., are discussed in the article Periodic law (vol. iii. p. 808); that article should be consulted.

The older classification by types prepared the way for the wider conception of valency, which took up and utilised the permanent features of the typical arrangements of elements and compounds. The study of valency led chemists to see the importance of examining the properties of the atoms of the elements, and thus made them ready to accept the more elastic, and more exact, generalisation of the periodic law. The theory of types developed into the theory of valency, and the theory of valency has been included in the theory of the periodicity of the connection between the atomic weights of the elements and the compositions and properties of the compounds of the elements. The general conception of types remains; we are still obliged to picture to ourselves a typical acid, a typical base, a typical salt, a typical alcohol, a typical amide, and so on. But this conception is no longer the basis of chemical classification. We have gone deeper down, and laid the foundations of our system on the firmer basis of the atomic weights of the elements. M. M. P. M.

TYPHOTOXINE $C_7H_{17}NO_2$. An alkaloid obtained from pure cultures of the typhogen bacillus (Gautier, *Bl.* [2] 48, 13).

TYROSINE $C_9H_{11}NO_3$ *i.e.* $C_6H_4(OH).CH_2.CH(NH_2).CO_2H$. *p-Oxy-α-amido-phenyl-propionic acid.* Mol. w. 181. [235°]. S.G. 1·456 (Siber, *B.* 17, 2837). S. ·04 at 20°; ·65 at 100°. S. (90 p.c. alcohol) ·0074 in the cold. H.F. 156,400. H.C.v. 1,070,800. H.C.p. 1,071,200 (Berthelot a. André, *Bl.* [3] 4, 227). $[\alpha]_D = -8°$ in HClAq at 16°; $-9°$ in KOHAq at 20° (Mauthner, *M.* 3, 343).

Occurrence.—Occurs abnormally in the liver and urine (*e.g.* in cases of poisoning by phosphorus (Frerichs a. Städeler, *J.* 1855, 729; 1856, 702; Blendermann, *H.* 6, 242), in the cutaneous scales in pellagra (Schmetzer, *Dissert.*, Erlangen, 1862), in cochineal (De la Rue, *A.* 64, 35), in sprouting pumpkin seeds (Schulze a. Barbieri, *J. pr.* [2] 20, 401; 32, 457), in the roots of *Stachys tuberifera* (Planta, *B.* 23, 1699), in dahlia bulbs (Leitgeb, *C. C.* 1888, 1397), in alcoholic extract of woad leaves (Schunck, *C. N.* 37, 223), and in beetroot molasses (Lippmann, *B.* 17, 2835).

Formation.—1. By potash fusion from caseïn (Liebig, *A.* 57, 127; 62, 269), globulin, feathers, hairs (Leyer a. Köller, *A.* 83, 332), and albumen (Nencki, *J. pr.* [2] 17, 97).—2. By the action of boiling dilute H_2SO_4 on ox-horn (Hinterberger, *A.* 71, 72), on fibrin (Städeler, *A.* 111, 12; 116, 57), and on silk (Weyl, *B.* 21, 1529).—3. By putrefaction of yeast (A. Müller, *J. pr.* 57, 162; Béchamp, *C. R.* 74, 115, 184), albumen and gelatin (Jeanneret, *J. pr.* [2] 15, 353).—4. In small quantity by heating conglutin with HClAq (Siegfried, *B.* 24, 419).—5. From *p*-amido-phenyl-alanine and HNO_2 (Friedländer a. Mähly, *B.* 16, 854; Erlenmeyer a. Lipp, *A.* 219, 161).

Properties.—Stellate groups of slender silky needles (from water), insol. alcohol and ether, m. sol. NH_3Aq and KOHAq. Lævorotatory. Its solution is not ppd. by lead acetate or subacetate until NH_3Aq is added. Boiling $Hg(NO_3)_2$ containing HNO_3 turns its solution red, forming a brownish-red pp. (R. Hoffmann, *A.* 87, 123; L. Meyer, *A.* 132, 156). After warming with conc. H_2SO_4, diluting with water, and neutralising with $BaCO_3$, the solution is turned violet by $FeCl_3$. Tyrosine gives off less N_2 when its solutions are decomposed by NaOH and Br in presence of NH_3 than when the NH_3 is absent.

Reactions.—1. At 270° it splits up into CO_2 and $C_6H_4(OH).CH_2.CH_2.NH_2$ (Schmitt a. Nasse, *A.* 133, 211).—2. *Potash-fusion* forms *p*-oxy-benzoic and acetic acids (Barth, *A.* 136, 110; Ost, *J. pr.* [2] 12, 159; Baumann, *H.* 4, 304). 3. $KClO_3$ and HClAq form tetra-chloro-quinone.—4. By *putrefactive fermentation* it is converted into hydro-*p*-coumaric acid, and finally into *p*-cresol and phenol (Weyl, *B.* 12, 1450).—5. HIAq and P at 150° from NH_3 and *p*-oxy-phenyl-propionic acid (Hüfner, *Z.* [2] 4, 391; 6, 113). Conc. HClAq and HBrAq at 240° have no action.—6. Conc. H_2SO_4 (4 pts.) at 100° forms crystalline $C_9H_{10}(SO_3H)NO_3$, v. sl. sol. cold water, which also occurs in a hydrated amorphous form (containing 2aq). H_2A'' yields $(NH_4)HA''$aq, $Ba(HA'')_2$ 4aq, and $Ca(HA'')_2$ 5aq (Städeler, *A.* 116, 57). $BaC_9H_9NO_3$ 3aq is obtained from the product of the action of H_2SO_4 (10 pts.) on tyrosine (1 pt.).—7. MeOH, potash, and MeI yield crystalline $C_{12}H_{18}NIO_3K$, sol. water, decomposed by warm KOHAq into NMe_3 and the methyl derivative of *p*-coumaric acid (Körner a. Menozzi, *G.* 11, 550).—8. *Potassium cyanate* added to boiling water containing tyrosine forms tyrosine-hydantoic acid $C_6H_4(OH).CH_2.CH(NH.CO.NH_2).CO_2H$ crystallising from water in needles, insol. ether (Jaffé, *H.* 7, 310). This body begins to melt at 155°, being decomposed above 170°. It gives a red colour and pp. on warming with Millon's reagent. It forms KA'aq, crystallising from alcohol-benzene.—9. *Tyrosine* administered to a dog appears in the urine as tyrosine-hydantoïn $C_6H_4(OH).CH_2.CH{<}\begin{smallmatrix}NH.CO\\ CO.NH\end{smallmatrix}$ [275°–280°], which crystallises from water in needles, and is decomposed by heating in sealed tubes with baryta-water into CO_2, ammonia and tyrosine. Other products found in the urine of a rabbit after a dose of tyrosine are hydro-*p*-coumaric and *p*-oxy-phenyl-acetic acids and phenols (Blendermann, *H.* 6, 251).

Salts. — $Na_2C_9H_9NO_3$. — $CaC_9H_9NO_3$. — $BaC_9H_9NO_3$ 2aq. Prisms, more sol. cold than hot water.—$Cu(C_9H_{10}NO_3)_2$. S. ·98 in the cold; ·4 at 100°. Got by adding $Cu(OH)_2$ to a boiling solution of tyrosine (Hofmeister, *A.* 189, 6). Insol. alcohol. Deposits black cupric oxide on boiling with water.—$C_9H_{11}NO_3(HgO)_2$ 2aq.—$C_9H_{11}NO_3(HgO)_2$ aq. — $C_9H_{11}NO_3(HgO)_3$ aq (Vintschgau, *J.* 1869, 985).—$Ag_2C_9H_9NO_3$ aq: amorphous pp. — $AgC_9H_{10}NO_3\frac{1}{2}$aq: crystalline powder. — B'HCl 2aq: needles, decomposed by water.—$B'_2H_2PtCl_6$ (Gintl, *Z.* [2] 5, 704).—$B'H_2SO_4$. Slender needles, not coloured by $FeCl_3$.

Di-bromo-tyrosine $C_9H_9Br_2NO_3$ 2aq. S. ·46 at 16°; 4 at 100°. Formed from dry tyrosine and Br vapour (Gorup-Besanez, *A.* 125, 281). Needles or tables (from water), sl. sol. alcohol. $Ag_2C_9H_7Br_2NO_3$ 2aq. — B'HCl 1½aq. — B'HBr. — $B'_2H_2SO_4$. Prisms, sol. water and alcohol.

Nitro-tyrosine $C_9H_{10}N_2O_5$ *i.e.* $C_9H_{10}(NO_2)NO_3$. Formed from tyrosine (1 pt.), water (4 pts.), and nitric acid (4 pts. of S.G. 1·3) in the cold (Strecker, *A.* 73, 70; Städeler, *A.* 116, 77). Pale-yellow needles, sl. sol. cold water. — Salts: $Ba(C_9H_9N_2O_5)_2$ (dried at 100°). Blood-red amorphous mass.—$Ag_2C_9H_8N_2O_5$ aq: orange pp. changing to a red powder.—B'HCl ½aq. Tufts of lemon-yellow needles.—$B'HNO_3$. S. 20. Lemon-yellow needles.—$B'_2H_2SO_4$. Yellow needles or granules.

Di-nitro-tyrosine $C_9H_9(NO_2)_2NO_3$. [115°]. Formed by warming nitro-tyrosine with dilute HNO_3. Golden plates (from water).—Salts: $CaC_9H_7N_3O_7$ 3aq. Golden six-sided tables.—$BaC_9H_7N_3O_7$ 2aq. Ruby-red prisms with yellow reflex, exploding when heated.

Reference.—AMIDO-TYROSINE.

TYROTOXICON. A poisonous substance formed in milk, containing the butyric acid ferment, which has stood for some days. Occurs also sometimes in cheese (Vaughan, *Ph.* [3] 18, 470; *H.* 10, 146). When its alcoholic solution is mixed with $PtCl_4$ and evaporated violent explosion takes place.

U

ULEXINE $C_{11}H_{14}N_2O$. [151°]. An alkaloid in the seeds of common furze (*Ulex europeus*) (Gerrard a. Symons, *Ph.* [3] 17, 101, 229; 19, 1029; 20, 978, 1017). Deliquescent crystals, v. sol. chloroform, insol. ether. Poison, paralysing respiration (Bradford, *J. Physiol.* 8, 79). Possibly identical with cytisine.—B'HCl. Deliquescent.—$B'H_2PtCl_6$.—$B'2HAuCl_4$.

ULTRAMARINE. The blue-coloured material contained in *lapis-lazuli*. Until 1828 ultramarine was obtained by powdering and washing *lapis-lazuli*; but since that year it has been manufactured by heating to bright redness mixtures of Al silicate (*china clay*), Na_2CO_3 (*carbonated soda ash*), S, and charcoal, and washing, powdering, drying, and sifting the product. (For details of the manufacture v. DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 891.) The constituent elements of ultramarine are Al, Na, Si, S, and O. Treated with HClAq, ultramarine gives off H_2S; the solution contains NaCl, $AlCl_3$, and SiO_2, and the residue consists of SiO_2, S, and some Al_2O_3; these reactions point to ultramarine being a compound of silicates and polysulphides. Much work has been done on the constitution of ultramarine, but the results obtained have not finally settled the question. From analyses and investigations made in 1891, Brögger a. Bäckström (*W. J.* 1891. 454) conclude that the composition of the essential colouring compound in natural ultramarine is represented by the formula $Na_4[Al(S_3Na)]Al_2(SiO_4)_3$. They also conclude that artificial ultramarines may be expressed by the following formulæ:—

$$Na_3Al_3Si_3O_{12} = N$$
$$Na_2Al_2Si_4O_{12} = A$$
$$Na_4[Al(SNa)]Al_2Si_3O_{12} = U(S_1)$$
$$Na_4[Al(S_2Na)]Al_2Si_3O_{12} = U(S_2)$$
$$Na_4[Al(S_3Na)]Al_2Si_3O_{12} = U(S_3).$$

The main constituents of the different varieties of blue ultramarine are N, A, and $U(S_3)$; of green ultramarine $U(S_2)$ and N; and $U(S_1)$ is the main constituent of white ultramarine, according to B. a. B. Formulæ more or less approaching those given above have been assigned to ultramarine by other observers; thus Silber in 1880 represented blue ultramarine as $Si_6Al_4Na_6S_4O_{20}$ (*B.* 13, 1854). On the other hand, some chemists have regarded the essential constituent of ultramarine as a sodium thiosilicate; for instance, Rickmann (*B.* 11, 2013 [1878]) gives $S.Si(ONa)_2$ as the composition of 'ideal ultramarine blue'; and he regards artificial ultramarine as a mixture, the only essential part of which is sodium thiosilicate. Clarke (*Am.* 10, 126) suggested a formula for ultramarine which should indicate the relations of this body to various natural silicates; in this respect Clarke's formula is important (*v.* this vol. p. 451).

White ultramarine is obtained by completely cutting off air during the roasting of the materials; it is changed to blue by heating in O, SO_2, or Cl (*v.* Ritter, *W. J.* 1160. 226; *cf.* Philipp, *B.* 9, 1109; 10, 1227; Böttinger, *A.* 182, 311; R. Hoffmann, *A.* 194, 1).

Red ultramarine was observed by Scheffer, in 1873, to be formed in preparing the ordinary substance in a muffle furnace very strongly heated and freely exposed to the air; it contains less Na and more Al than the blue variety (*B.* 6, 1450; *v.* also Büchner, *D. P. J.* 231, 446; Zettner, *B.* 8, 259, 353).

Yellow ultramarine is formed by heating the red variety in the air a little above 360°, for a short time (R. Hoffmann, *A.* 194, 1). According to Büchner (*B.* 7, 990), both the yellow and red forms are produced by heating blue ultramarine to 300°-400° in O or SO_2; the colour changes to red and then to yellow. If Cl is passed over ultramarine before the formation of the blue variety is completed, at 410°, the colour goes green, and then reddish-yellow (Zettner, *B.* 8, 259, 353); by heating the product with alkali, all Cl is removed and a *violet ultramarine* is produced. This variety goes to the red form when heated in vapour of HNO_3 or HCl at 130°-150° (Zettner, *l.c.*).

Green ultramarine is formed when a little Sn is used in the roasting process; it is converted into the blue substance by roasting with S. This form seems to be intermediate between white and blue ultramarine. According to Philipp (*B.* 9, 1109), S is not taken up in the change from green to blue; by heating the green form in sealed tubes with water, at 100°, he obtained the blue, the water removing a very small quantity of sodium compounds.

Substituted ultramarines. Blue to green, and reddish-grey, substances have been formed by heating ultramarine with $AgNO_3Aq$, and by treating the product of this reaction with KI, LiI, BaI_2, ZnI_2, &c. These substances, known as *silver ultramarine*, *potassium ultramarine*, &c., probably contain Ag, K, Li, Ba, &c., in place of Na (*v.* Unger, *D. P. J.* 212, 224, 301; Philipp, *B.* 10, 1227; Heumann, *A.* 199, 253; 201, 262; Forcrand a. Ballin, *Bl.* [2] 30, 112). By heating silver ultramarine with various alcoholic iodides, Forcrand (*C. R.* 88, 30) obtained ultramarines containing alcoholic radicles, such as *ethyl ultramarine*, *amyl ultramarine*, &c. *Selenion* and *tellurium ultramarines* have also been produced, wherein S is substituted by Se or Te (*v.* Leykauf, *W. J.* 1876. 555; Guimet, *A. Ch.* [5] 13, 102; Plicque, *Bl.* [2] 28, 518; Morel, *Bl.* [2] 28, 522). Various substituted ultramarines have been examined by Wunder (*Chem. Zeit.* 1890. 1119). M. M. P. M.

ULMIC ACID. C. 66·4–63·9; H. 4·6–4·5; O. 29–31·5. $C_{18}H_{14}O_8$ or $C_{18}H_{16}O_7$. H.C. 1983, 200. H.F. 266,200. Formed by action of HCl on cane sugar. Is an anhydride or mixture of anhydrides $C_{18}H_{14}O_8$ (humic anhydride) (Berthelot a. André, *Bl.* [3] 7, 441, 451). Turns yellow in air and sunlight, giving off CO_2. The same thing happens with the humic acid extracted from vegetable mould by KOHAq and ppd. by HCl. Dilute alkalis cause it to swell up, forming insoluble *salts* and a small quantity of a soluble basic salt. When conc. KOHAq is used a salt is formed, from which two-thirds of the alkali can be removed by washing, leaving $KC_{18}H_{15}O_7aq$, and is reconverted into the acid $C_{18}H_{16}O_7$ by HClAq. Ammonia converts humic anhydride (ulmic acid) into an amido- acid $C_{54}H_{47}NO_{18}NH_3$, whence HCl sets free $C_{54}H_{47}NO_{19}$.

Salts.—$KC_{18}H_{15}O_7$ aq. Hard, black, insoluble mass, yielding a brown powder. The 'ulmin' of Malaguti. Formed by shaking the anhydride with KOH (1 pt.) and water (120 pts.). —$NaC_{18}H_{15}O_7$ aq.—$Na_3C_{18}H_{13}O_7$ *x*aq.

References.—Humic, Saccharumic, and Sacculmic acids.

UMBELLIC ACID $C_9H_8O_4$ *i.e.* [4:2:1] $C_6H_3(OH)_2.CH{:}CH.CO_2H$. Mol. w. 132. Di-oxy-cinnamic acid. Formed by warming its lactone, umbelliferone with KOHAq (Tiemann a. Reimer, *B.* 12, 994; Posen, *B.* 14, 2745). Yellowish powder. Turns brown at 240°, and decomposes below 260°. Sol. alcohol and warm water, insol. ether. Resinified by boiling its aqueous solution. Reduces warm ammoniacal $AgNO_3$, forming a mirror. $FeCl_3$ gives a brown pp.

Methyl derivative $C_{10}H_{10}O_4$. [180°–185°]. Got by heating herniarin with alcoholic potash at 160° (Barth a. Herzig, *M.* 10, 165). Needles (from water).

(α)-*Di-methyl derivative* $C_6H_3(OMe)_2.CH{:}CH.CO_2H$. [138°]. Formed by the action of MeI and KOH in MeOH on the methyl derivative of umbelliferone in the cold (W. Will, *B.* 16, 2115; 19, 1777). Needles, v. sol. alcohol and ether. Converted into the (β)-isomeride by boiling alone or with HClAq. Both isomerides are reduced by sodium-amalgam to the same $C_6H_3(OMe)_2.CH_2.CH_2.CO_2H$, and are oxidised by $KMnO_4$ to the same $C_6H_3(OMe)_2.CO_2H$. —CaA'_2 2aq: crystals.—BaA'_2 2aq: needles.

(β)-*Di-methyl derivative.* [184°]. Formed as above, and also by saponification of its methyl ether $C_6H_3(OMe)_2.CH{:}CH.CO_2Me$ [87°], which is got by evaporating methyl-umbelliferone (1 mol.) with NaOH (2 mols.) nearly to dryness, and digesting the residue with MeI and MeOH (Tiemann a. Will, *B.* 15, 2079). Needles, sol. alcohol and ether. Sl. sol. cold water.

(α)-*Di-ethyl derivative* [4:2:1] $C_6H_3(OEt)_2.C_2H_2.CO_2H$. *Di-ethyl-umbellic acid.* [107°]. Formed by mixing ethyl-umbelliferone (5 g.) with EtI (10 g.) and a solution of KOH (4 g.) in alcohol (Will a. Beck, *B.* 19, 1780). Small plates, v. sol. alcohol, ether, and benzene.

(β)-*Di-ethyl derivative.* [200°]. Formed by boiling the (α)-isomeride for some time, and also by heating ethyl-umbelliferone (10 g.) with EtI (9 g.) and a solution of Na (2⅓ g.) in alcohol for six hours at 150°. Crystals, m. sol. alcohol, sl. sol. water.

UMBELLIFERONE $C_9H_6O_3$ *i.e.*  $C_6H_3(OH)<\begin{matrix}CH{:}CH\\ O{-}CO\end{matrix}$. Mol. w. 162. [224°]. S. 1 at 100°. Formed by the dry distillation of various resins, chiefly those derived from umbelliferous plants, *e.g.* galbanum, sagapenum, and asafœtida (Sommer a. Zwenger, *A.* 115, 15; Mössmer, *A.* 119, 260; Hlasiwetz a. Grabowski, *A.* 139, 100; Hirschsohn, *C. C.* 1877, 182). Formed by heating malic acid (1 mol.) with resorcin (1 mol.) and H_2SO_4 (Pechmann, *B.* 17, 932). Prepared by distilling the alcoholic extract of gum galbanum (Tiemann a. Reimer, *B.* 12, 993). Needles, sl. sol. cold water and ether, v. sol. alcohol. Dissolves in acids, without change. Alkalis above 50° form umbellic acid. Its solution in dilute alkalis shows blue fluorescence. H_2SO_4 forms a solution with green fluorescence. Reduces $AgNO_3$ on boiling. Yields (4,2,1)-di-oxy-benzoic acid on oxidation (Tiemann a. Parrisius, *B.* 13, 2354). Fuming HNO_3 and H_2SO_4 form $C_9H_4(NO_2)_2O_3$ [216°] (Posen, *B.* 14, 2744).

Acetyl derivative $C_{11}H_8O_4$. [140°]. Formed by acetylation, and also by boiling di-oxy-benzoic aldehyde with Ac_2O and NaOAc (Tiemann, *B.* 10, 2216; 12, 995). Needles, sl. sol. water.

Methyl derivative $C_{10}H_8O_3$ *i.e.*  $C_6H_3(OMe)<\begin{matrix}CH{:}CH\\ O{-}CO\end{matrix}$. [114°]. Formed by heating umbelliferone with KOMe and MeI (T. a. R.). Leaflets, nearly insol. water. Appears to be identical with herniarin [118°], which is extracted by alcohol from *Herniaria hirsuta* (Barth a. Herzig, *M.* 10, 161).

Ethyl derivative $C_{11}H_{10}O_3$. [88°]. Plates, v. sol. alcohol (Will a. Beck, *B.* 19, 1779).

Oxim of the methyl derivative  $[4{:}2{:}1]\,C_6H_3(OMe)<\begin{matrix}CH{:}CH\\ O{-}C{:}NOH\end{matrix}$. [138°]. Formed from the methyl derivative of thio-umbelliferone and hydroxylamine (Aldringen, *B.* 24, 3465). Needles, v. sol. hot water and alcohol. $FeCl_3$ colours its solution brownish-red.

Phenyl-hydrazide of the methyl derivative  $C_6H_3(OMe)<\begin{matrix}CH{:}CH\\ O{-}C{:}N_2HPh\end{matrix}$ [115°]. Yellow needles, giving a blue colour with H_2SO_4.

Thio-umbelliferone. *Methyl derivative* $C_6H_3(OMe)$$<\begin{matrix}CH:CH\\O-CS\end{matrix}$. [114°]. Formed by heating the methyl derivative of umbelliferone with P_2S_5 (Aldringen, *B.* 24, 3465). Needles, sol. alcohol, v. sl. sol. water.

References.—BROMO- and METHYL- UMBELLIFERONE.

UMBELLOL $C_8H_{12}O$. (216°). V.D. 4·29. Occurs in the volatile oil of the Californian laurel (Stillmann, *B.* 13, 679). Oil, sol. H_2SO_4 with red colour, becoming black. Attacked by Na.

UMBELLULIC ACID *v.* HENDECOÏC ACID.

UNDECANE *v.* HENDECANE.

UNDECOÏC ACID *v.* HENDECOÏC ACID.

UNDECOLIC ACID *v.* HENDECINOIC ACID.

UNDECYLENE *v.* HENDECYLENE.

UNDECYLENIC ACID *v.* HENDECENOIC ACID.

UNDECYLIC ACID *v.* HENDECOÏC ACID.

URACIL $CO<\begin{matrix}NH.CH\\NH.CO\end{matrix}>CH$. *Di-oxy-pyrimidine.* Derivatives of this compound are formed by the action of acetoacetic ether on urea, thio-urea, and guanidine (Behrend, *A.* 229, 1; 240, 6; List, *A.* 236, 1; Jäger, *A.* 262, 365; Warmington, *J. pr.* [2] 47, 201).

Amido-uracil $C_4H_5N_3O_2$. Formed, together with oxyuracil $C_4H_4N_2O_3$, by reducing nitro-uracil (Behrend), and by boiling di-bromo-pyruvuramide with baryta-water (Fischer, *A.* 239, 193). Yellow needles, sol. water. Converted by cyanic acid into oxyxanthine $C_5H_6N_4O_3$, which crystallises in needles, sl. sol. water, sol. alkalis, gives with Cl the murexide reaction, may be oxidised to alloxantin, and gives some alloxan with bromine-water.

Acetyl derivative $C_7H_9N_3O_3\frac{1}{2}aq$. Prisms.

Nitro-uracil *v.* NITRO-DI-OXY-PYRIMIDINE.

Bromo-nitro-oxy-uracil. *Dihydride* $C_4H_4N_3O_5Br$ *i.e.* $CO<\begin{matrix}NH.CH(OH)\\NH.CO\text{———}\end{matrix}>CBr(NO_2)$. Formed by adding Br to nitro-uracil suspended in water (Behrend, *A.* 240, 11). Crystalline mass, sl. sol. cold water and alcohol. Boiling with water produces brominated nitro-methanes and a crystalline compound $C_5H_7N_5O_5$, formed by the action of urea upon nitro-uracil. Tin and HCl reduce it to amido-uracil.

Methyl-uracil *v.* DI-OXY-METHYL-PYRIMIDINE.

Nitro-methyl-uracil $C_5H_5N_3O_4$. Prepared by nitrating methyl-uracil with HNO_3 (S.G. 1·5) mixed with an equal volume of H_2SO_4 (S.G. 1·84) (Behrend, *A.* 240, 3). Prisms or tables (from water), sl. sol. hot alcohol.

Isomeride *v.* NITRO-DI-OXY-METHYL-PYRIMIDINE.

Nitro-di-methyl-uracil *v.* NITRO-DI-OXY-DI-METHYL-PYRIMIDINE.

Di-chloro-oxy-methyl-uracil. *Dihydride* $C_5H_6Cl_2N_2O_3$ *i.e.* $CCl_2<\begin{matrix}CMe(OH).NH\\CO\text{———}NH\end{matrix}>CO$. Formed by the action of chlorine on methyl-uracil suspended in water (Behrend, *A.* 236, 59). Tables (from water); slowly decomposed by boiling water. M. sol. alcohol; not decomposed by boiling alcohol. M. sol. ether. A solution of $SnCl_2$ in HClAq at 100° reduces it to chloro-methyl-uracil $C_5H_5ClN_2O$, which crystallises from water in needles. Fuming HNO_3 gives di-chloro-barbituric acid.

Di-bromo-oxy-methyl-uracil $C_5H_6N_2Br_2O_3$ *i.e.* $CBr_2<\begin{matrix}CMe(OH).NH\\CO\,.\,NH\,.\,CO\end{matrix}>$. From methyl-uracil (or bromo-methyl-uracil), and bromine-water (Behrend, *A.* 229, 18; 236, 57). Cubes (from hot water). Boiling alcohol converts it into bromo-methyl-uracil $C_5H_5N_2BrO_2$. Fuming HNO_3 forms di-bromo-barbituric acid.

Di-chloro-oxy-tri-methyl-uracil. *Dihydride* $CO<\begin{matrix}NMe.CO\text{———}\\NMe.CMe(OH)\end{matrix}>CCl_2$. [144°]. Formed by passing Cl into an aqueous solution of tri-methyl-uracil (Hagen, *A.* 244, 14). Crystals, sl. sol. hot water. Reduced by boiling with $SnCl_2$ to chloro-tri-methyl-uracil, which crystallises in prisms, m. sol. hot water.

Nitro-ethyl-uracil *v.* NITRO-DI-OXY-ETHYL-PYRIMIDINE.

Methyl-ethyl-uracil *v.* DI-OXY-METHYL-ETHYL-PYRIMIDINE.

Nitro-methyl-ethyl-uracil *v.* NITRO-DI-OXY-METHYL-ETHYL-PYRIMIDINE.

Amido-uracil carboxylic acid *v.* DI-OXY-AMIDO-PYRIMIDINE CARBOXYLIC ACID.

References.—THIO-METHYL-URACIL and UR-AMIDO-CROTONIC ACID.

URAMIDO - ACETIC ACID *v.* HYDANTOÏC ACID.

***p*-URAMIDO-BENZENE SULPHONIC ACID** $NH_2.CO.NH.C_6H_4.SO_3H$. Formed by evaporating a solution of *p*-amido-benzene sulphonic acid and potassium cyanate (Pellizzari, *A.* 248, 156), and also by heating dry *p*-amido-benzene sulphonic acid (1 mol.) with urea ($1\frac{1}{2}$ mols.) (Friedel, *C. R.* 112, 868). Pearly plates (from dilute alcohol), v. sol. water.—$BaA'_2 3aq$; monoclinic prisms, sol. Aq.

***o*-URAMIDO-BENZOIC ACID** $C_8H_8N_2O_3$ *i.e.* $NH_2.CO.NH.C_6H_4.CO_2H$. Formed from potassium cyanate and the hydrochloride of *o*-amido-benzoic acid (Griess, *J. pr.* [2] 5, 371; *B.* 11, 1730). HNO_3 yields only one di-nitro- derivative.

***m*-Uramido-benzoic acid** $C_8H_8N_2O_3$. S. 1 at 100°. S. (96 p.c. alcohol) ·72 at 16°. S. (ether) ·127 at 16°. Occurs in urine after a dose of *m*-amido-benzoic acid (E. Salkowski, *H.* 7, 113).

Formation.—1. By adding potassium cyanate to a boiling saturated solution of the sulphate of *m*-amido-benzoic acid (Menschutkin, *A.* 153, 84; *Z.* [2] 4, 275).—2. By fusing *m*-amido-benzoic acid with urea (Griess, *Z.* [2] 5, 312; *B.* 2, 47). 3. By boiling *m*-cyanamido-benzoic acid with HClAq (Traube, *B.* 15, 2122).

Properties.—Small prisms (containing aq), v. sl. sol. hot water. At 200° it yields $CO(NH.C_6H_4.CO_2H)_2$. On distilling *m*-uramido-benzoic acid (4 pts.) with P_2O_5 (1 pt.) *m*-amido-benzoic nitrile [54°] is formed (Griess, *B.* 8, 224). Boiling KOHAq splits it up into *m*-amido-benzoic acid, CO_2, and NH_3.

Salts.— $NH_4A'aq$. — KA'. — $CaA'_2 4aq$. — $PbA'_2 2aq$.—AgA': curdy pp., becoming crystalline.

Ethyl ether EtA'. [176°]. Formed from *m*-amido-benzoic ether and KCyO (Griess, *J. pr.* [2] 4, 293). Plates, sl. sol. hot water.

Amide $C_8H_9N_3O_2$. Formed from *m*-amido-benzamide and KCNO (Menschutkin). Scales (from water), decomposed by fusion, sl. sol. alcohol.

***p*-Uramido-benzoic acid** $C_8H_8N_2O_3$. Formed in like manner (Griess, *J. pr.* [2] 5, 369). Plates, almost insol. cold water, v. sl. sol. hot water, m. sol. hot alcohol. Yields some *p*-amido-benzonitrile [86°] on distilling with P_2O_5.—BaA'_2. Plates, v. e. sol. cold water.

Di-uramido-benzoic acid $C_9H_{10}N_4O_4$ *i.e.* $(NH_2.CO.NH)_2C_6H_3.CO_2H$. Formed by fusing di-amido-benzoic acid with urea (Griess, *B.* 2, 47). Small granules, v. sl. sol. hot water.—BaA'_2 (dried at 130°). Nodules, v. sol. hot water.

References.—AMIDO-, NITRO-, and OXY- URAMIDO-BENZOIC ACIDS.

URAMIDO-BENZOYL *v.* OXY-QUINAZOLINE.

***p*-URAMIDO-BENZYL-UREA** $C_9H_{12}N_4O_2$ *i.e.* $NH_2.CO.NH.C_6H_4.CH_2.NH.CO.NH_2$. [197°]. *p-ω-Di-uramido-toluene.* Formed by heating together *p*-amido-benzyl-amine hydrochloride (1 mol.), and KCNO (2 mols.) in aqueous solution (Amsel a. Hofmann, *B.* 19, 1289). Small needles. Sol. hot water.

URAMIDO-ISOBUTYRIC ACID *v.* ACETON-URAMIC ACID.

***o*-URAMIDO-CINNAMIC ACID** $C_{10}H_{10}N_2O_3$ *i.e.* $NH_2.CO.NH.C_6H_4.CH:CH.CO_2H$. Formed from *o*-amido-cinnamic acid and aqueous KCNO (Rothschild, *B.* 23, 3341). Sol. NH_3Aq and hot HClAq.

(β)-URAMIDO-CROTONIC ACID $C_5H_8N_2O_3$ *i.e.* $CH_3.C(NH.CO.NH_2):CH.CO_2H$. The ether is converted by NaOHAq into the salt NaA′, which crystallises in needles, v. sol. water; but on adding acids to this salt di-oxy-methyl-pyrimidine $C_5H_6N_2O_2$ is produced. Methyl-uracil is reconverted by NaOHAq into sodium uramido-crotonate (Behrend, *A.* 229, 5).

Ethyl ether EtA′. [166°]. Formed from acetoacetic ether and urea. Needles, v. sol. ether, m. sol. alcohol. Decomposed by warm HClAq into urea, acetone, CO_2, and alcohol. Alcohol forms $CH_3.C(NH.CO_2Et):CH.CO_2Et$ [29°] (Meister, *A.* 244, 234).

Amide $CH_3.C(NH.CO.NH_2):CH.CO.NH_2$. [131°]. Crystals (containing EtOH) (Meister).

Amido-uramido-crotonic acid. *Lactam.*

$C_5H_3(NH_2)N_2O_2$ *i.e.* $CO<\begin{matrix}NH.CMe\\NH.CO\end{matrix}>C.NH_2$ (?).

Amido-methyl-uracil. Methyl-uracil (*v.* DI-OXY-METHYL-PYRIMIDINE) is converted by Br in CS_2 into crystalline bromo-methyl-uracil $C_5H_5BrN_2O_2$, whence conc. NH_3Aq at 150° forms amido-methyl-uracil (Behrend, *A.* 231, 250). Satiny plates (from water), melting near 250°. Sol. alcohol. The hydrochloride is converted by potassium cyanate into oxy-methyl-xanthine $C_6H_8N_4O_3$ 2aq, crystallising from water in prisms.—B′HCl aq. Monoclinic crystals; $a:b:c = 1{\cdot}629:1:2{\cdot}345$; $\beta = 52°\ 57'$.—$B'_2H_2PtCl_6$ 2aq: needles, v. sol. water.

Acetyl derivative $C_5H_3(NHAc)N_2O_2\frac{1}{2}aq$. Formed from oxy-methyl-xanthine and Ac_2O at 170°. Thick trimetric prisms (from water). Decomposes near 210° without melting. Sol. alkalis and reppd. by acids.

URAMIDO-ETHANE SULPHONIC ACID $NH_2.CO.NH.CH_2.CH_2.SO_3H$. *Taurocarbamic acid.* Occurs in small quantity in urine after a dose of taurine (E. Salkowski, *B.* 6, 744, 1191). Formed by evaporating a solution of taurine with KCyO. Formed also by the action of bromine-water on ethylene-ψ-thio-urea (Gabriel, *B.* 22, 1142). Dimetric plates, v. sol. water, sl. sol. alcohol, insol. ether. Decomposed by baryta-water at 140° into CO_2, taurine, and NH_3.—BaA'_2: tables (from alcohol).—AgA′. Radiating tufts of crystals.

URAMIDO-HEXOIC ACID $C_7H_{14}N_2O_3$ *i.e.* $NH_2.CO.NH.CH(C_4H_9).CO_2H$. [200°]. Formed by boiling isobutyl-hydantoïn with baryta-water (Pinner a. Spilker, *B.* 22, 696). Needles, v. sol. alcohol and hot water.—BaA'_2: nodular groups of prisms.

Ethyl ether EtA′. [135°]. Formed by heating isobutyl-hydantoïn with KOH and EtBr. Needles, v. sol. alcohol and hot water.

Nitrile. $NH_2.CO.NH.CH(C_4H_9).CN$. Formed by heating the cyanhydrin of isovaleric aldehyde with urea (Pinner a. Lifschütz, *B.* 20, 2351). Oil, sol. alcohol and ether. On warming with HClAq it yields isobutyl-hydantoïn

$C_4H_9.CH<\begin{matrix}CO.NH\\NH.CO\end{matrix}$ [210°].

Amide $NH_2.CO.NH.CH(C_4H_9).CO.NH_2$. [170°]. Formed from the nitrile (1 pt.) and conc. H_2SO_4 (3 pts.) in the cold. Crystals, v. sol. water and alcohol.

URAMIDO-HIPPURIC ACID $C_{10}H_{11}N_3O_4$. Formed by fusing *m*-amido-hippuric acid with urea (Griess, *J. pr.* [2] 1, 235). Nodules, v. e. sol. hot water. Decomposed by boiling conc. HClAq into glycocoll and *m*-uramido-benzoic acid.—AgA′. Crystalline pp.

URAMIDO-NITRO-AMIDO-PHENOL $C_7H_8N_4O_4$ *i.e.* $C_6H_2(NO_2)(NH_2)(NH.CO.NH_2).OH$. Formed by reducing di-nitro-oxy-phenyl-urea with ammonium sulphide (Griess, *J. pr.* [2] 5, 1). Reddish-brown needles, sl. sol. hot water and alcohol.—B′HCl: white scales.—BaA'_2 $3\frac{1}{2}aq$: steel-blue needles, v. sol. hot. water. Boiling HClAq converts it into amidocarboxamidonitrophenol $C_7H_5N_3O_4$, which yields BaA'_2 *x*aq and B′HCl aq, and is reduced by tin and HClAq to diamidocarboxamidophenol $C_7H_7N_3O_2$, which yields B′HCl, crystallising in plates.

URAMIDO-DI-NITRO-PHENOL *v.* DI-NITRO-OXY-PHENYL-UREA.

***p*-URAMIDO-PHENYL-ACETIC ACID** $NH_2.CO.NH.C_6H_4.CH_2.CO_2H$. [174°]. Formed by boiling *p*-cyanamido-phenyl-acetic acid with HClAq (Traube, *B.* 15, 2122). Small crystals (containing $1\frac{1}{2}aq$), sol. water, alcohol, and ether.

α-Uramido-phenyl-acetic acid. *Ethyl ether* $NH_2.CO.NH.CHPh.CO_2Et$. [139°]. Formed by the action of aqueous KCyO on the hydrochloride of α-amido-phenyl-acetic ether (Kossel, *B.* 21, 4150). V. sol. alcohol and hot water.

Nitrile $NH_2.CO.NH.CHPh.CN$. [170°] Formed by heating the cyanhydrin of benzoic aldehyde with urea (Pinner a. Lifschütz, *B.* 20, 2351). Converted by acids into $C_9H_8N_2O_2$ [182°], crystallising in scales, v. sol. alcohol and hot water.

α-URAMIDO-PHENYL-CROTONIC ACID. *Nitrile* $CHPh:CH.CH(NH.CO.NH_2).CN$. [160°]. Formed by heating urea with the cyanhydrin of cinnamic aldehyde (Pinner a. Lifschütz, *B.* 20, 2351). Needles, v. sol. hot alcohol. Boiling HClAq converts it into di-oxy-styryl-pyrazole (*q.v.*).

Amide $CHPh:CH.CH(NH.CO.NH_2).CO.NH_2$. Formed from the nitrile and cold conc. H_2SO_4 (Pinner a. Spilker, *B.* 22, 692). Microcrystalline powder, decomposing at 210°–220° with evolution of NH_3. Sol. alcohol, sl. sol. hot water.

a-URAMIDO-PROPIONIC ACID $C_4H_8N_2O_3$ *i.e.* $CH_3.CH(NH.CO.NH_2).CO_2H$. *Lacturamic acid.* [155°]. Formed by evaporating a solution of alanine sulphate mixed with KCyO (Urech, *A.* 165, 99). Formed also by boiling lactyl-urea with baryta-water (Heintz, *A.* 169, 128). Prisms, sl. sol. cold water and alcohol, insol. ether.—BaA'_2aq (dried at 100°).—$PbA'2aq$.—AgA': needles, m. sol. water.

Nitrile $CH_3.CH(NH.CO.NH_2).CO_2H$. [106°] (Franchimont a. Klobbie, *R. T. C.* 7, 16).

Amide $CH_3.CH(NH.CO.NH_2).CO.NH_2$. [196°]. Small needles (from alcohol), sol. water.

URAMIDO-SUCCINIC ACID. Amic acid $NH_2.CO.CH_2.CH(NH.CO.NH_2).CO_2H$. [138°] (G.); [157°] (P.). *Succinuramide. Amido-succinuric acid.* S. 5·4 at 23°. Formed by evaporating the mixed solutions of asparagine KCyO (Guareschi, *G.* 7, 404; *B.* 10, 1747). Dextro-asparagine gives a lævo- compound, while lævo-asparagine gives a dextro- compound (Piutti, *B.* 19, 1693). Prisms, nearly insol. alcohol and ether. According to Piutti, the dextro- and lævo- compounds both melt at 157°.

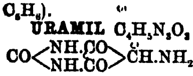
Reactions.—1. Decomposed by fusion, with formation of malyl-ureide $C_5H_7N_3O_3$ [230°–235°], which is also formed by heating urea with asparagine at 125° (Grimaux, *A. Ch.* [5] 11, 400) and crystallises from water in pointed rhombohedra.—2. Boiling HClAq (S.G. 1·12) forms malyl-ureidic acid $C_5H_6N_2O_4$, which is also got by heating aspartic acid with urea at 130°. Malyl-ureïdic acid crystallises in prisms [215°–220°], S. 25 at 100°, which yields BaA'_2aq and is converted by heating with bromine-water into $C_9H_6Br_6N_4O_6$, S. 3 at 100°, $C_9H_4Br_4N_4O_5$, S. ·25 at 100°, $C_9H_4Br_2N_4O_5$, which is v. sol. water, $C_8H_5BrN_4O_4$, S. c. 6 at 100°, and $C_4H_4Br_2N_2O_3$, S. 10 in the cold and c. 22 at 100°.

URAMIDO-THIO-FORMIC ACID *v.* THIO-ALLOPHANIC ACID.

DI-URAMIDO-TOLUENE *v.* URAMIDO-BENZYL-UREA.

DI-*p*-URAMIDO-DI-*o*-TOLYL-SULPHIDE [2:1:4] $S(C_6H_3Me.NH.CO.NH_2)_2$. *Thio-p-tolyl-di-urea.* [151°] (when containing benzene of crystallisation). Formed by heating the hydrochloride of di-*p*-amido-di-tolyl-sulphide with KCNO (Trehlar, *B.* 20, 669). Crystallises from benzene in white silky needles (containing C_6H_6).

URAMIL $C_4H_5N_3O_3$ *i.e.*



$CO<\begin{matrix}NH.CO\\NH.CO\end{matrix}>CH.NH_2$. *Dialuramide. Amido-barbituric acid. Amido-malonyl-urea. Murexan.* Mol. w. 143. Formed by boiling alloxantin with NH_4Cl (Liebig a. Wöhler, *A.* 26, 310; Grimaux, *C. R.* 87, 752) and by boiling ammonium thionurate with HClAq. Formed also by reducing nitro- or nitroso- barbituric acid with HIAq (Baeyer, *A.* 127, 223). It is also a product of the action of acids on murexide (Beilstein, *A.* 107, 183).

Properties.—Silky needles, sl. sol. hot water, insol. alcohol and ether. Sol. conc. H_2SO_4 and re-ppd. on dilution. Its alkaline solution turns red in air, forming purpurates; thus it is converted, in ammoniacal solution into murexide by boiling with air or HgO. Conc. HNO_3 forms alloxan. Bromine at 85° forms orange $C_4H_4BrN_3O_3$ (Mulder, *B.* 14, 1060).

URAMILIC ACID $C_8H_9N_5O_7$ (?). S. 14 in the cold; 33 at 100°. Formed by heating uramil with H_2SO_4 and water, or by evaporating ammonium thionurate with some H_2SO_4 (Liebig a. Wöhler, *A.* 26, 314; Gregory, *P. M.* 24, 187). Transparent, four-sided prisms, sl. sol. cold water. Converted by boiling conc. HNO_3 into nitro-barbituric acid.

URANATES *v.* URANIUM, OXYACIDS AND SALTS OF, p. 826.

URANIUM. U. At. w. 239 (not determined with very great accuracy). Mol. w. unknown. M.P. not determined accurately; between red heat and white heat. S.G. of fused U at $\frac{18°}{4°}$ = 18·685 (Zimmermann, *B.* 15, 851). S.H. at 100° = ·0276 (Z., *l.c.*). S.V.S. 12·8.

Historical.—In 1789 Klaproth prepared some compounds of a new element from *pitchblende*; to the characteristic element of these compounds he gave the name uranium, from *οὐρανός* = the heavens, in allusion to the planet *Uranus* which had been discovered a few years before (*Crell's A.* 1789 [2] 400). The compounds of U were examined by Richter (*Gehlen's A.* 4, 402), Buchholz (*Gehlen's A.* 4, 17, 134), Lecanu (*J. Ph.* 9, 141; 11, 279), Brande (*S.* 44, 1), Berzelius (*P.* 1, 359), and Arfvedson (*P.* 1, 245). In 1840, Péligot showed that the substance supposed till then to be U was really an oxide of U (*A. Ch.* [3] 5, 5); P. isolated the metal, and determined the at. w. to be 120. Mendeléeff in 1872 (*A. Suppl.* 8, 133; *cf. C. N.* 41, 39 [1880]) proposed to double the at. w. of U, making it 240; this proposal was completely justified by the determination of S.H. of pure U by Zimmermann in 1882 (*B.* 15, 851), and by the determination of the V.D. of UCl_4 and UBr_4 (Z., *A.* 216, 2 [1883]).

Occurrence.—Never uncombined. A few minerals containing compounds of U are found sparsely distributed and not in large quantities; the chief of these is *pitchblende*, which consists of U_3O_8 along with SiO_2 and oxides of Sb, As, Ca, Cu, Fe, Mg, V, &c. Carbonate, sulphate, phosphate, niobate, tantalate, and various other compounds of U are also found in varying quantities in several rare minerals (*v.* Zimmermann, *A.* 232, 300; Hidden a. Mackintosh, *Am. S.* [3] 38, 474; Hillebrand, *Am. S.* [3] 38, 329; 40, 384). Lockyer (*Pr.* 27, 49) stated that some of the lines in the emission-spectrum of U coincide with dark lines in the solar spectrum. Hutchins a. Holden (*P. M.* [5] 24, 325) think there is no trustworthy evidence in favour of the existence of U in the solar atmosphere.

Preparation.—1. A mixture of UCl_4, NaCl, and Na is strongly heated in a closed iron cylinder. Zimmermann (*A.* 116, 14) used a cylinder of soft iron with walls c. 3 centim. thick, bored from a larger cylinder (similar to that employed by Nilson a. Pettersson for preparing Be; *B.* 11, 383) fitted with a cap which could be screwed on tightly. He placed a layer of pure fused NaCl in the cylinder, then small pieces of Na (c. 3 to 4 pts. for 10 pts. UCl_4), then UCl_4 (which must be put into the cylinder as quickly as possible, as it is hygroscopic), and covered the whole with a layer of fused NaCl. Z. raised the cylinder to a white heat, kept it at that temperature for some time, cooled, and washed the contents with dilute alkali solution, and then with water. According to Z., the metal as thus prepared is quite pure (*v. infra*).—2. Moissan (*C. R.* 116, 347) obtained U, containing from 5 to 13·5 p.c. C, by mixing the oxide prepared by strongly heating $UO_2(NO_3)_2$ with excess of charcoal, compressing the mixture in a carbon crucible, imbedding this in MgO, and heating for 10–12 minutes in an electric furnace, using a current of 60 volts and 450 ampères.

UCl_4 is obtained by heating the nitrate $UO_2(NO_3)_2$ in air, mixing the oxide thus obtained (chiefly U_3O_8) with C, and heating in a stream of Cl (*v.* URANIUM TETRACHLORIDE, p. 823). The nitrate is obtained from *pitchblende* by powdering the mineral, washing with water, drying, and washing to remove S and As, dissolving in HNO_3Aq, evaporating to dryness, dissolving in water, filtering from Fe_2O_3, $PbSO_4$, &c., evaporating a little, and allowing to crystallise. The crystals of $UO_2(NO_3)_2$ thus obtained are purified by draining in a funnel, washing with a little cold water, drying in the air, dissolving in ether in a wide-mouthed bottle, crystallising by spontaneous evaporation, and re-crystallising from hot water; the crystals of $UO_2(NO_3)_2$ are then dissolved in water so as to form a conc. solution, $UO_2.C_2O_4$ is ppd. by adding $H_2C_2O_4Aq$ to this solution, the pp. is washed with boiling water, and then decomposed by heat, and the UO_2 thus produced is digested with conc. HClAq, washed, dissolved in HNO_3Aq, and the solution is crystallised (Péligot, *A. Ch.* [3] 5, 5; 12, 258; *cf.* Ebelmen, *A.* 43, 286; Wertheim, *J. pr.* 29, 209).

The oxide U_3O_8 used by Zimmermann (*v. supra*) for the preparation of UCl_4, from which pure U was obtained, was prepared by him as follows. A warm solution of commercial uranium hydroxide in HClAq was saturated with H_2S; after standing for some time the liquid was filtered off, NH_3Aq and $(NH_4)_2CO_3Aq$ were added in excess, the liquid was warmed and $(NH_4)_2SAq$ was added; after standing the liquid was filtered, saturated with HClAq, and boiled till CO_2 was removed, then mixed with NH_3Aq and $(NH_4)_2SAq$ and heated on the water-bath till most of the $(NH_4)_2S$ was removed; the pp. of UO_2 was collected, washed, and heated over the blowpipe; the U_3O_8 thus formed was dissolved in HNO_3Aq and the solution was crystallised; the crystals of $UO_2(NO_3)_2$ were dissolved in ether, the solution was poured off from insoluble substances, evaporated to dryness, and the residue was strongly heated; the U_3O_8 which remained was again dissolved in HNO_3Aq, and the crystals that formed on evaporation were dissolved in ether, and the ethereal solution was evaporated to dryness and the residue decomposed by heating.

Properties.—A lustrous, hard, silver-white metal; S.G. 18·685 at $\frac{13^\circ}{4^\circ}$ (Zimmermann, *B.* 15, 851); if UCl_4 is reduced by Na at a red heat, U is obtained as a greyish-black powder. S.H. at 100° = ·0276 (Z., *l.c.*). U is somewhat malleable, but cannot be hammered into thin plates. The emission-spectrum, obtained by the aid of electric sparks, shows only a few lines, the most marked being one in the yellow (Thalén, *A. Ch.* [4] 18, 239). For the fluorescence, phosphorescence, and absorption-spectra of U compounds *v.* Becquerel (*A. Ch.* [4] 27, 539), also Morton a. Bolton (*Am. Ch.* 3, 361, 401). U melts towards a white heat; according to Moissan (*C. R.* 116, 1429), the metal is volatilised by heating in an electric furnace using a current of 350 ampères and 75 volts. After long standing in the air the surface of U becomes covered with a steel-blue to black film of oxide; U that has been fused burns brilliantly when heated on Pt foil in the air; pulverulent U burns at 150°–170° in the air. U combines directly with Cl or Br, also with S; the metal dissolves in dilute H_2SO_4Aq or HClAq; it is not acted on by acetic acid, nor by KOHAq, NaOHAq, or NH_3Aq.

The at. w. of U has been determined (1) by determining U and Cl in UCl_4 (Péligot, *A. Ch.* [3] 5, 12 [1842]; Rammelsberg, *P.* 55, 318; 56, 125 [1842]); (2) by analyses of $UO_2.C_2O_4.H_2O$ (Ebelmen, *A. Ch.* [3] 5, 191 [1842]; Péligot, *A. Ch.* [3] 20, 341 [1846]); (3) by analyses of $UO_2(C_2H_3O_2)_2.2H_2O$ (Péligot, *l.c.*; Wertheim, *J. pr.* 29, 207); (4) by analyses of the double salt $UO_2.Na(C_2H_3O_2)_3$ (Wertheim, *l.c.*); (5) by transforming UO_2 into U_3O_8, and $UO_2.Na(C_2H_3O_2)_3$ into Na_2UO_4 (Zimmermann, *A.* 232, 117, 273 [1886]); (6) by determining S.H. of U (Zimmermann, *B.* 15, 851 [1882]); (7) by determining V.D.s of UBr_4 and UCl_4 (Z., *A.* 216, 2 [1883]).

The at. w. of U was formerly taken as c. 120; in 1872 Mendeléeff adduced reasons for doubling this value, based on a comparative study of the properties of compounds of U to which he was led by considering the periodic arrangement of the elements (*A. Suppl.* 8, 178; *C. N.* 41, 39). When the at. w. of U was taken as 120, the formulæ given to the chief oxides, chlorides, and salts of this element were UO, UCl_2, USO_4, &c.; U_3O_4; U_2O_3, UOCl, $UO_2(NO_3)$, &c.; and U was classed with the iron metals. Mendeléeff pointed out that U was very much heavier than the iron metals, that the oxide U_2O_3 did not form salts similar to those derived from Fe_2O_3, that the salts of UO, *i.e.* USO_4, $U(NO_3)_2$, &c., were not isomorphous with the salts of MgO, FeO, NiO, &c. Mendeléeff also drew attention to the existence of a chloride which would have to be represented as U_2Cl_5 if U = 120, and that this chloride was obtained by heating UCl_2 in H. Mendeléeff proposed to double the value then accepted for the at. w. of U, and, following on this, to write the formulæ of the chlorides, oxides, and salts as UCl_4, UO_2, $U(SO_4)_2$, &c.; U_3O_8; UO_3, UO_2Cl_2, $UO_2(NO_3)_2$, &c.; and UCl_5. It was pointed out that many of these formulæ are analogous to those of the corresponding compounds of Cr, Mo, and W; and it was shown that the properties of compounds of U more nearly resemble those of compounds of Cr, Mo, and W than of any other elements. Especial stress was laid by Mendeléeff on the acidic character of the highest oxide of U. Finally, Mendeléeff showed that an element with the properties of U, and an at. w. equal to c. 240, finds its proper place in Group VI., series 12, of the periodic arrangement of the elements. Mendeléeff suggested that the S.H. of pure U should be determined; that the V.D. of the volatile chloride should be found; that the action of H on the chloride then taken to be UCl_2 should be studied; that salts of the lower oxide (UO if U = 120, UO_2 if U = 240) should be examined, especially as regards their isomorphism with salts of ThO_2, SnO_2, ZrO_2, and TeO_2; that the crystalline forms of corresponding compounds of MoO_3, WO_3, and UO_3 (U = 240) should be studied, and that an especially thorough crystallographic examination should be made of the compounds $R_2UO_2F_4$; and that the physical properties of compounds of Cr, Mo, W, and U should be compared. Since the publication of Mendeléeff's memoir, the S.H. of U, and the V.D.s of UBr_4 and UCl_4 have been determined, the action of H on UCl_4 has been examined, and something has been done in the study of the crystalline forms of compounds of U, including those of the form $R_2UO_2F_4$; the results of all these investigations fully confirm the justness of Mendeléeff's view that the at. w. of U is c. 240, and that this element must be classed with Cr, Mo, and W. The exact value to be given to the at. w. of U has not been yet determined; Zimmermann's measurements gave 238·75 from the ratio $UO_2:U_3O_8$, and 238·67 from the ratio $UO_2Na(C_2H_3O_2)_3:Na_2UO_4$ (O = 15·96). The mol. w. of U is not known.

U is the last member of the even-series family of Group VI.; this family also contains, besides O, the elements Cr, Mo, —, and W. The chromium elements are both metallic and non-metallic in their chemical relations; they form oxides MO_3 that are acidic, and some of the lower oxides are basic. The oxide UO_2 forms some corresponding salts; a series of salts of the form UO_2X is also known, where $X = SO_4$, &c. Several series of uranates M_2UO_4, $M_2U_2O_7$, &c., are known. The haloid compounds are UX_3, UX_4, and UX_5. (For a comparison of the metals of the Cr family *v.* Chromium group of elements, vol. ii. p. 168; *cf.* Classification, vol. ii. p. 207.)

The atom of U is tetravalent in the gaseous molecules UBr_4 and UCl_4.

Reactions and Combinations.—1. Heated in ***air*** U is burnt to a voluminous deposit of U_3O_8 (perhaps containing also UO_2), which stops the further oxidation of the metal. Pulverulent U burns when heated in air to 150°–170°.—2. U burns brilliantly when heated in *chlorine*, forming UCl_4; heated in *bromine* to c. 240° part of the metal is changed to UBr_4.—3. Heated in ***sulphur*** vapour US_2 is produced.—4. It is generally said that U does not react with *water*; but, according to Moissan (*C. R.* 116, 347), the metal obtained by him by reducing the oxide by charcoal in an electric furnace decomposed water at the ordinary temperature; this specimen of U contained from 5 to 13·5 p.c. C.—5. U dissolves in *dilute sulphuric acid*, rapidly on warming, forming USO_4, and giving off H; pulverulent U dissolves in hot conc. H_2SO_4, giving off SO_2; the compact metal is scarcely acted on by conc. H_2SO_4.—6. U dissolves in *hydrochloric acid*, dilute or conc., rapidly on warming, forming a hyacinth-red solution of UCl_3, which goes green on shaking in air, and then contains UCl_4.—7. *Conc. nitric acid*, even when hot, scarcely acts on U that has been fused; the pulverulent metal is quickly oxidised by hot conc. HNO_3Aq to U_3O_8.—8. Several *metallic salts* in solution are reduced by U, with ppn. of the metals, *e.g.* $HgNO_3$, $AgNO_3$, $CuSO_4$, $SnCl_2$, $PtCl_4$, $AuCl_3$.

Detection and Estimation.—Uranyl salts ($UO_2.SO_4$, &c.) are formed by heating uranates with acids, also by the reactions of acids with UO_3, and also by oxidising uranous salts (salts of UO). K_4FeCy_6Aq gives a brownish-red pp. with uranyl salts, soluble in HClAq or in $(NH_4)_2CO_3Aq$; this reaction is said to be extremely delicate; H_2O_2Aq and alcohol give a brown pp. (Fairley, *C. N.* 62, 227); carbonates give yellow pps., soluble in excess, forming yellow liquids; NaOHAq or KOHAq forms yellow pps., NH_4ClAq does not interfere with the ppn., but in presence of sugar or tartaric acid pps. are not produced. Uranous salts are produced by reducing uranyl salts in solution by Zn and HClAq. After reduction the solutions give green pps. with KOHAq or NaOHAq, the pps. becoming brown and then yellow in the air; with $(NH_4)_2SAq$ green pps. are formed, quickly becoming dark green, and black on boiling; K_4FeCy_6Aq produces yellow-green pps. becoming red in the air (*v.* Zimmermann, *A.* 213, 285).

U is generally estimated as UO_2 or U_3O_8 (*v.* Zimmermann, *A.* 232, 209). Solutions may be reduced by Zn and H_2SO_4Aq, and then titrated with $KMnO_4Aq$, the quantity of O used corresponding with the change of UO_2 to UO_3 (Z., *l.c.*; *v.* also Bělohoubek, *J. pr.* 99, 231).

Uranium, arsenates of. A compound, probably $UO_2.As_2O_5.4aq$, is described by Rammelsberg (*P.* 59, 26). Werther (*J. pr.* 43, 321) describes $UO_2H_2AsO_4.3aq$, and various *double salts* of this compound with arsenates of Ca, Cu, and Na.

Uranium, bromides of. UBr_4 is formed by heating U_3O_8 mixed with C in Br vapour; and UBr_3 by heating UBr_4 in H. Zimmermann (*A.* 216, 5) failed to obtain a compound with more Br by heating UBr_4 with Br to 230° in a sealed tube.

Uranium tetrabromide UBr_4. (*Uranous bromide.*) Mol. w. 558. Prepared by strongly heating a mixture of U_3O_8 and sugar, mixing with sugar charcoal that has been heated to redness, placing the mixture in a tube, and heating it first in a stream of thoroughly dried CO_2, and then in Br vapour, and allowing to cool in CO_2; the Br used must be perfectly freed from Cl, HBr, and H_2O by distillation from KBr, MnO_2, and P_2O_5 (Zimmermann, *A.* 216, 2; Alibegoff, *A.* 232, 132; *cf.* Hermann, *J.* 1861. 260). UBr_4 forms black, fusible leaflets; volatile at red heat, giving a vapour with V.D. 281 (Z., *l.c.*); very hygroscopic; dissolves in water, with a hissing sound, forming a green liquid.

By evaporating a solution of $UO_2.xH_2O$ in HBrAq, Rammelsberg (*P.* 59, 12) obtained green crystals of hydrated UBr_4, probably $UBr_4.8H_2O$.

Uranoxybromides. (*Bromoxy-uranates.*) $UO_2Br_2.2MBr$ or $M_2UO_2Br_4$. By the reaction of HBrAq with K_2UO_4 and $(NH_4)_2UO_4$ respectively, Sendtner (*A.* 195, 325) obtained yellowish, hygroscopic tablets of the composition $M_2UO_2Br_4.2H_2O$, where M = NH_4 and K.

Uranium tribromide UBr_3. Mol. w. not determined. Obtained by Alibegoff (*A.* 233, 119; *cf.* Zimmermann, *A.* 216, 5) by passing dry H over molten UBr_4. Dark-brown needles; easily volatilised; not changed by continued heating in H; very hygroscopic; warmed in H_2S, in complete absence of air, forms U_2S_3.

Uranium, chlorides of. By heating U in Cl both UCl_5 and UCl_4 are produced; and by heating UCl_4 in H, UCl_3 is formed.

URANIUM PENTACHLORIDE UCl_5. Mol. w. not determined; formula probably molecular, from analogy of $MoCl_5$ and WCl_5.

Preparation.—1. By heating U in excess of Cl.—2. A slow stream of dry Cl is passed over a mixture of charcoal and any oxide of U, or UO_2Cl_2, heated to dull redness in a glass tube; dark-green octahedral crystals of UCl_4 are formed near the heated part of the tube, and in front of these needle-shaped crystals of UCl_5 are deposited, mixed with a loose brown powder, which is also UCl_5. If the stream of Cl is rapid, most of the UCl_5 is produced as a light-brown, mobile powder (Roscoe, *C. J.* [2] 12, 933).

Properties and Reactions.—UCl_5 crystallises in long, dark, needle-shaped forms; the crystals are lustrous, and reflect greenish light, in transmitted light they are dark ruby red. Both the crystals and the brown powder are very hygroscopic. Dissolves in water, with a hissing sound, forming a yellow-green liquid and giving off HCl. Decomposed to UCl_4 and Cl when heated, either alone or in CO_2 or Cl; decomposition begins at 120° in CO_2, and is complete at 235°. Heating in NH_3 probably produces a nitride (Roscoe, *l.c.*; no analyses given).

Combination.—A compound $UCl_5.PCl_5$ is described by Cronander (*J.* 1873. 222) as an amorphous, yellow solid; formed by heating UO_2 with excess of PCl_5 in a sealed tube for a long time.

URANIUM TETRACHLORIDE UCl_4. (*Uranous chloride.*) Mol. w. 380·48.

Preparation.—1. U is heated in Cl.—2. A mixture of charcoal and an oxide of U, or UO_2Cl_2, is heated in a slow stream of dry Cl (Péligot, *A.* 43, 258; *cf.* Roscoe, *C. J.* [2] 12, 933). The crystals that form nearest to the heated part of the tube are again heated in a stream of dry CO_2, whereby traces of UCl_5 are volatilised and removed (Zimmermann, *A.* 216, 8).—3. A solution of ammonium uranate in HClAq is reduced by Zn, and the solution is evaporated and crystallised. Arendt a. Knop (*C. C.* 1857. 164) reduced, by boiling the solution for 15 min. with Cu and a little $PtCl_4Aq$; they then filtered, saturated with H_2S, filtered, boiled off H_2S, and crystallised.

Properties and Reactions. — Dark-green, lustrous, regular octahedral crystals; volatilises at red heat, in complete absence of moisture, giving a red vapour (Péligot, *l.c.*) with V.D. 192 (Zimmermann, *l.c.*). Very deliquescent; fumes much in air, giving off HCl; dissolves in water, with a hissing sound, forming a green solution that is unchanged in air; gives green, amorphous UCl_4 by evaporation *in vacuo*, but is decomposed by evaporation in the air. When UCl_4Aq is dropped into boiling water all the U is ppd. as $UO_2.xH_2O$. Solution of UCl_4 reduces salts of Au and Ag to the metals, and $FeCl_3$ to $FeCl_2$, &c. By heating in dry H one-fourth of the Cl is removed and UCl_3 remains (Péligot, *A.* 43, 266). According to Péligot (*l.c.*), UCl_4 combines with several metallic chlorides to form double salts.

Uranoxychlorides. (*Chloroxyuranates.*) $UO_2Cl_2.2MCl.2aq$, or $M_2UO_2Cl_4.2aq$. Salts of this composition, $M = NH_4$ and K, are produced by the reaction of large excess of HClAq with uranates of NH_4 and K (Péligot, *A.* 43, 279). The K compound is also formed by acting on UO_2Cl_2 with excess of KClAq, and separating the KCl that crystallises with the $K_2UO_2Cl_4$ mechanically (Berzelius, *P.* 1, 366). The K compound forms thick plates (for crystalline measurements *v.* de la Provostaye, *A. Ch.* [3] 6, 165); easily loses water; gives off HCl at a little above 100°; melts at red heat, giving off Cl, and leaving UO_2 and KCl. The ammonium compound forms very deliquescent rhombohedra.

URANIUM TRICHLORIDE UCl_3. Mol. w. not determined. Obtained by Péligot (*l.c.*) by heating UCl_4 in dry H as long as HCl was given off. Also formed in solution by long-continued reduction of uranyl salts by Zn and HClAq (Zimmermann, *A.* 213, 300). A brownish-red solid; dissolves very readily in water, forming a red solution, which gives off H and becomes green (*v.* P., *l.c.*; Z., *l.c.*; also *A.* 216, 12).

Uranium, ferrocyanides of. Various compounds are described by Wyruboff (*A. Ch.* [5] 8, 444) and Atterberg (*Bl.* [2] 21, 355) as obtained by ppg. K_4FeCy_6Aq by solutions of salts of U. The following formulæ are given:

(1) $U_2FeCy_6.10aq$; (2) $U_2K_2FeCy_6.6aq$;
(3) $(UO_2)_3K_2(FeCy_6)_2.6aq$;
(4) $(UO_2)_5K_6(FeCy_6)_4.12aq$.

Uranium, fluorides of. Only one compound, UF_4, has been isolated with certainty.

URANIUM TETRAFLUORIDE UF_4. (*Uranous fluoride.*) Mol. w. not determined; formula probably molecular, from analogy of UBr_4 and UCl_4. Prepared by adding HFAq to U_3O_8, boiling, pouring off the yellow solution (which contains UO_2F_2), washing the green powder that remains, first on a filter and then by decantation, until free from HFAq, and drying at 100° (Smithells, *C. J.* 43, 125; *cf.* Bolton, *Z.* [2] 2, 353). The process of washing is very tedious, and occupies many days. UF_4 is a green powder; insol. in water and dilute acids; slowly dissolved by conc. acids; boiling NaOHAq produces UO_2. Heated in a Pt crucible with the lid on, a small quantity of a white, bulky sublimate is obtained; this sublimate is UO_2F_2 (Smithells, *l.c.*); the residue in the crucible is chiefly UO_2. Heated on Pt foil, UF_4 leaves U_3O_8 (S., *l.c.*).

Double salts.—Bolton (*l.c.*) obtained the compounds $UF_4.KF$ and $UF_4.NaF$—as green powders, insoluble in water and dilute acids, giving UO_2, KF (or NaF), and HF when heated to redness, in closed vessels—by the action of formic or oxalic acid on $UO_2F_2.3KF$ or $UO_2F_2.NaF$ (*v. infra*) in sunlight. These compounds may be called *uranofluorides*, and written KUF_5 and $NaUF_5$.

Uranium hexafluoride UF_6 was said by Ditte (*C. R.* 91, 115) to be formed by heating U_3O_8 with HFAq, evaporating the yellow liquid, and heating the crystals of $UF_6.8HF$ thus obtained; but Smithells (*C. J.* 43, 125) has shown that the substance obtained by evaporating the *solution formed by heating U_3O_8 with HFAq is* UO_2F_2 (*v.* URANIUM OXYFLUORIDE, p. 828).

Uranoxyfluorides. (*Fluoxy-uranates.*) These compounds may be regarded either as double salts of UO_2F_2 with alkali fluorides, or as salts derived from hypothetical acids $H_xUO_2F_y$. The compounds are formed by adding alkali fluorides to solutions of uranous nitrate, and crystallising under different conditions (*v.* Bolton, *Z.* [2] 2, 353; Baker, *C. J.* 35, 763). The compounds that have been isolated belong to several series: (1) $MF.UO_2F_2.x aq = MUO_2F_3.x aq$, where $M = Na$ and $x = 2$ and 4 (Bolton); (2) $3MF.UO_2F_2 = M_3UO_2F_5$, where $M = NH_4$ and K (Bolton; Baker); (3) $3KF.2UO_2F_2.2aq = K_3U_2O_4F_7.2aq$ (Baker); (4) $5KF.2UO_2F_2 = K_5U_2O_4F_9$ (Baker); (5) $3BaF_2.5UO_2F_2.2aq$ (Bolton). Two other series were described by Ditte (*C. R.* 91, 166), $4MF.UO_2F_2$ and $4MF.UOF_4.x aq$; but the experiments of Smithells (*C. J.* 43, 131) have shown that these compounds do not exist.

Uranium, haloid compounds of. U combines directly with Br and Cl, but not with I; no iodide, indeed, has been isolated. The haloid compounds of U belong to the form UX_3, where $X = Br$ or Cl; UX_4, where $X = Br$, Cl or F; and UX_5, where $X = Cl$. The compounds UBr_4 and UCl_4 have been gasified, and the formulæ are molecular. From the analogy of WCl_6 and $MoCl_5$ the formula UCl_5 is probably molecular; this compound decomposes to UCl_4 and Cl when heated, either alone or in CO_2 or Cl. From the analogy of $CrCl_3$ it may be supposed that UCl_3 and UBr_3 are molecular formulæ. No haloid compounds of U have been isolated corresponding with the chlorides of Cr, Mo, and W, M_xCl_{2x}. No haloid compounds of U are known containing each more than one halogen. Various oxyhaloid compounds, chiefly UO_2X_2, and compounds of these with alkali haloids, are known.

Uranium, hydroxides of, *v.* URANIUM, OXIDES AND HYDRATED OXIDES OF (*infra*); also URANIUM OXYACIDS, AND SALTS OF (p. 826).

Uranium, iodides of. No compound of U and I has been isolated. Hermann (*J.* 1861. 260) and Sendter (*Verbind. des Uraniums*, Erlangen, 1877) failed to obtain an iodide by heating a mixture of UO_2 and C in I vapour or in HI.

Uranium, nitride of, U_3N_4. A greyish-black powder; obtained by heating UCl_4 in NH_3, then mixing with NH_4Cl and heating for a long time in a stream of NH_3 (Uhrlaub, *Verbind. einiger Metalle mit Stickstoff*, Göttingen, 1859). Roscoe (*C. J.* [2] 12, 933) states that a nitride is formed by heating UCl_5 in NH_3, but no analyses are given.

Uranium, oxides and hydrated oxides of. When U is burnt in air the product is U_3O_8; by heating this oxide with reducers, or for a long time in a stream of N or CO_2, UO_2 is formed; UO_3 is produced by fusing U_3O_8 with $KClO_3$, also by heating $UO_2(NO_3)_2$; by adding H_2O_2Aq to $UO_2(C_2H_3O_2)_2Aq$ or $UO_2(NO_3)_2Aq$ a hydrate of UO_4 is obtained. Besides these four oxides, others, intermediate between UO_2 and UO_3, perhaps exist. No definite hydrate of UO_2 has been isolated; the pp. formed by adding NH_3Aq to UCl_4Aq, or to solution of a uranous salt ($U(SO_4)_2$, &c.), is either a hydrate, or a mixture of hydrates, of UO_2. A hexahydrate of U_3O_8 probably exists. Uranic acid is the monohydrate of UO_3. UO_2 dissolves in some acids to form corresponding salts; U_3O_8 is said to react with conc. H_2SO_4 or HClAq to form both uranous salts UX_2, and uranyl salts UO_2X, where X = a divalent acidic radicle. UO_3 interacts with several acids to form uranyl salts UO_2X^{II}; UO_3 also reacts as an acidic oxide with strong bases, forming uranates, di-uranates, &c., $M^I_2UO_4$, $M^I_2U_2O_7$, &c.

According to Guyard (*Bl.* [2] 1, 89), two oxides having the compositions UO and U_3O_4 exist; but the more accurate investigations of Zimmermann (*A.* 213, 301) showed that the substances examined by Guyard were not definite compounds. Péligot described a black oxide U_2O_5; Zimmermann (*A.* 232, 273) has shown that the substance is a mixture, in variable proportions, of UO_2 and U_3O_8.

URANIUM DIOXIDE UO_2. (*Uranous oxide.*) Mol. w. not known. This oxide was supposed to be the element U until 1840, when Péligot proved the presence of O in the substance (*A. Ch.* [3] 5, 5).

Formation.—1. By heating U_3O_8 with such reducing agents as H (Arfvedson, *P.* 1, 245), NH_4Cl and S (Hermann, *J.* 1861. 258), a little C (Buchholz, *Gehlen's Ann.* 4, 17, 134), oxalic acid (Wertheim, *J. pr.* 29, 211), &c.—2. By heating U_3O_8 for a long time in a stream of N or CO_2 (Zimmermann, *A.* 232, 283).—3. By strongly heating $UO_2.C_2O_4$ in absence of air (Berzelius, *P.* 1, 359), or in a stream of H (Péligot, *A. Ch.* [3] 5, 5; Ebelmen, *A. Ch.* [3] 5, 189).

Preparation.—A mixture of UO_2Cl_2 and excess of NaCl and NH_4Cl is strongly heated in absence of air; and the product is washed thoroughly with water, and dried (Wöhler, *A.* 41, 345; *cf.* Hillebrand, *Zeit. f. anorg. Chemie*, 3, 243). If air is not excluded during heating, some UO_3 is obtained (H., *l.c.*). This process gives UO_2 as a black crystalline powder. In place of using UO_2Cl_2, a solution of ammonium uranate in HClAq may be mixed with excess of NaCl and NH_4Cl, and evaporated to dryness, and the residue heated. By fusing any oxide of U with borax for 24 hours, and washing with water and then with dilute acetic acid, or dilute HClAq, Hillebrand (*l.c.* p. 249) obtained jet-black octahedra of UO_2 isomorphous with ThO_2.

Properties.—Prepared by heating $UO_2.C_2O_4$, UO_2 is a dark-brown, pyrophoric powder; if the temperature has been kept high the oxide is lustrous, reddish-black, and not pyrophoric; prepared by heating UO_2Cl_2 with NaCl and NH_4Cl, UO_2 forms black, non-pyrophoric, octahedral crystals. Péligot gave S.G. 10·15; according to Hillebrand (*l.c.*), the S.G. is nearly 11. UO_2 is insoluble in water, HClAq, and dilute H_2SO_4Aq; it dissolves in HNO_3Aq, and in conc. H_2SO_4 in presence of a little water. UO_2 is oxidised to U_3O_8 by heating in air.

Reactions.—1. Heated in *air* or *oxygen* U_3O_8 is produced; UO_2 burns brilliantly in the O-H flame (Clarke, *G. A.* 62, 353).—2. Heating in *chlorine* produces UO_2Cl_2; when mixed with *carbon* and heated in *chlorine*, UCl_5 and UCl_4 are formed. UBr_4 is produced by heating UO_2 mixed with *carbon* in *bromine* vapour.—3. U_3O_8 is formed by heating UO_2 in *water vapour*

(Regnault, *A. Ch.* [2] 62, 358).—4. Heating in vapour of *carbon disulphide* produces $U_3O_2S_4$ (Hermann, *J.* 1861. 258; H. Rose, *G. A.* 73, 139). UO_2 is said to be unchanged by heating in *hydrogen sulphide* (Arfvedson, *P.* 1, 245).—5. A solution of UO_2 in conc. *sulphuric acid* gives green crystals of $U(SO_4)_2$ on evaporation.

HYDRATES OF URANIUM DIOXIDE. No definite hydrate of UO_2 has been isolated; NH_3Aq produces a reddish-brown pp. when added to UCl_4Aq or solution of a uranous salt, this pp. becomes black on boiling; when washed with air-free water and dried *in vacuo* it forms black, coherent lumps. A black pp. is also produced by dropping UCl_4Aq into boiling water. These black pps. contain UO_2; they are probably hydrates of this oxide. The name *uranous hydroxide* is often given to the pp. obtained by either of the processes described; the pp. dissolves in dilute H_2SO_4Aq, HNO_3Aq, and HClAq.

URANOSO-URANIC OXIDE U_3O_8. (*Olive-green oxide of uranium. Uranyl uranate* $UO_2.2UO_3$.) Mol. w. not known.

Occurrence.—In combination with SiO_2, and oxides of Sb, As, Ca, Cu, Fe, Mg, &c., in *pitchblende.*

Preparation.—U, or a decomposable U compound, *e.g.* $UO_2(NO_3)_2$, is heated in the air and then in a stream of O, and is allowed to cool in O (*v.* Zimmermann, *A.* 232, 283). For a method of preparing U_3O_8 from *pitchblende v.* URANIUM, *Preparation of* (p. 821).

Properties.—A dark olive-green powder, sometimes almost black, but always showing a green streak when rubbed on unglazed porcelain (Z., *l.c.*). S.G. 7·2 (Karsten, *S.* 65, 394); 7·31 (Ebelmen, *J. pr.* 27, 385). S.H. ·07979 (Donath, *B.* 12, 742). Insoluble in water; slightly soluble in dilute HClAq or H_2SO_4Aq; soluble in HNO_3Aq, also in H_2SO_4 with a little water.

Reactions.—1. Gives off O when heated in *air* or in an *indifferent gas*; the final product of heating in N or CO_2 is UO_2 (Zimmermann, *A.* 232, 283).—2. Reduced to UO_2 by heating with *hydrogen, carbon, sulphur, potassium,* or *sodium.* 3. Heated in vapour of *carbon disulphide* $U_3O_2S_4$ is formed.—4. Heated with *conc. sulphuric acid,* or with *hydrochloric acid* to 180°–200°, gives both uranous and uranyl sulphates, or chlorides; reacting as $UO_2.2UO_3$ (Z., *A.* 232, 287).—5. *Silver nitrate* solution is slowly reduced to Ag (Isambert, *C. R.* 80, 1087).

HYDRATE OF URANOSO-URANIC OXIDE. By adding NH_3Aq to UCl_4Aq and allowing the pp. to oxidise in the air, and drying *in vacuo* over H_2SO_4, Rammelsberg (*P.* 55, 319) obtained a greenish-black solid which may have been a hydrate of U_3O_8; one determination of water only is given which agrees fairly with $U_3O_8.6aq$.

URANIUM TRIOXIDE UO_3. (*Uranic oxide. Uranic anhydride. Uranyl oxide* $(UO_2)O$.) Mol. w. not known. This oxide is obtained by carefully heating the hydrate $UO_3.H_2O$ (*v. infra*) to 300° (Ebelmen, *A. Ch.* [2] 5, 199); to 250°, temperature being gradually raised (Jacquelin, *Ph. C.* 1845. 183). The oxide is also formed by heating $UO_2.CO_3.2(NH_4)_2CO_3$ to 300° (E., *l.c.*). The preparation of UO_3 may be conducted by heating $UO_2(NO_3)_2$ in a Pt basin until decomposition begins, then transferring to glass tubes and heating these in an oil-bath to 250° so long as acid fumes are given off.

UO_3 is a chamois-yellow powder. S.G. 5·02 to 5·26 (Brauner a. Watts, *P. M.* [5] 11, 60). Ebelmen (*l.c.*) described UO_3 obtained by heating $UO_2.CO_3.2(NH_4)_2CO_3$ as a sealingwax-red powder. When UO_3 is heated to redness it gives off O and U_3O_8 remains (E., *l.c.*; *cf.* Read, *C. J.* 65, 313 [1894]); the oxide seems to be somewhat volatile at the temperature of a porcelain oven (Elsner, *J.* 1866. 35).

UO_3 reacts with many acids as a basic oxide, but the salts formed are always basic salts of the forms $UX_6.2UO_3$, where X = the radicle of a monobasic acid, and $UX_3.2UO_3$ where X = the radicle of a dibasic acid. It is customary to write the formulæ of these basic salts as $UO_2.X^I_2$ and $UO_2.X^{II}$, and to call them *uranyl* salts (UO_2 = uranyl); thus $\frac{U(NO_3)_6.2UO_3}{3} = UO_2(NO_3)_2$, and $\frac{U(SO_4)_3.2UO_3}{3} = UO_2(SO_4)$.

UO_3 behaves towards strong bases as an acidic oxide, forming uranates M_2UO_4, and diuranates $M_2U_2O_7$, &c.; these salts are generally formed by fusing U compounds with bases and O, and by ppg. uranyl salt solutions by strong bases. When KOHAq, NaOHAq, NH_3Aq, BaOAq, or CaOAq is added to a solution of a uranyl salt, *e.g.* to $UO_2(NO_3)_2Aq$, the pp. consists of a uranate of the metal of the base. Alkali carbonates ppt. alkali uranates, but the pps. contain also CO_2; the pps. dissolve in excess of the alkali carbonates forming double carbonates of uranyl and the alkali metal, *e.g.* $UO_2.CO_3.2(NH_4)_2CO_3$. Addition of alkali or alkali carbonate to solutions of uranyl salts containing other metallic salts causes ppn. of a uranate of the metal of the salt present, generally mixed with alkali uranate (*cf.* URANIUM, OXYACIDS, AND SALTS THEREOF, p. 826).

By adding KOHAq to a cold solution of UCl_4 or $UO_2(NO_3)_2$, and dialysing, Graham (*T.* 1861. 213) obtained a solution, free from acid and alkali, which he regarded as a loose compound of sugar and UO_3, and which he called *sucrate of peroxide of uranium.*

HYDRATES OF URANIUM TRIOXIDE. Pure hydrates of UO_3 are not obtained by ppg. uranyl salt solutions by alkalis (*v. supra*); but according to Ebelmen (*A. Ch.* [3] 5, 199) $UO_3.xH_2O$ is produced by boiling an aqueous solution of $UO_2.CO_3.2(NH_4)_2CO_3$ until a yellow pp. is formed, and allowing this pp. to stand for a long time. By the continued action of sunlight on $UO_2(C_2O_4)$ in presence of water, $UO_3.xH_2O$ is said to be formed; after washing and drying in the air, the solid has the composition $UO_3.2H_2O$; and after drying *in vacuo* the composition is $UO_3.H_2O$ (E., *l.c.*). Berzelius (*B. J.* 24, 118) obtained $UO_3.H_2O$ by heating $UO_2(NO_3)_2$ on a sand-bath until acid fumes ceased to be given off, washing the residue with boiling water, and drying in air. The same hydrate is said to be formed by heating U_3O_8 with $KClO_3$ until fusion begins, boiling out with water, and drying in air (Drenkmann, *J.* 1861. 256). The best method of preparing $UO_3.H_2O$ seems to be that given by Malaguti (*A. Ch.* [3] 9, 463), viz. boiling a solution of $UO_2(NO_3)_2$ in absolute alcohol as long as a reaction proceeds, washing the yellow solid that separates with water, and drying in air or *in vacuo*; $EtNO_3$, N_2O_3, C_2H_4O, and $H.CO_2H$ are formed in the reaction.

$UO_3.H_2O$ is described as a yellow powder; S.G. 5·93 at 15° (Malaguti, *l.c.*); reddens litmus paper; when hot it absorbs CO_2 from the air; heated to 250°–300° water is given off and UO_3 remains (Ebelmen, *l.c.*; Jacquelin, *A. Ch.* [3] 5, 199); heated to redness gives off O and leaves U_3O_8. $UO_3.H_2O$ is generally called *uranic acid*; *v.* Uranium oxyacids, and salts thereof (*infra*).

Uranium peroxide. By adding $UO_2(NO_3)_2Aq$ to a mixture of H_2O_2Aq and a large excess of H_2SO_4Aq, and allowing to stand for a considerable time, Fairley (*C. J.* 31, 13[illegible] [1877]) obtained a small quantity of a heavy, crystalline, almost white pp., which when dried (? in air, or at 100°) had the composition UO_4. By adding dilute H_2O_2Aq to solution of $UO_2(NO_3)_2$ or $UO_2(C_2H_3O_2)_2$, free from acids, Fairley (*l.c.* p. 127) obtained a yellowish-white pp., which when dried by pressure between filter paper, had the composition $UO_4.4H_2O$, and when dried at 100° the composition $UO_4.2H_2O$.

Zimmermann (*A.* 232, 273 [1886]) failed to obtain the tetrahydrate $UO_4.4H_2O$; according to him the dihydrate $UO_4.2H_2O$ is very hygroscopic, and begins to decompose at 115°. Alibegoff also obtained only $UO_4.2H_2O$; he failed to prepare the anhydrous oxide UO_4 (*A.* 233, 123 [1886]).

Hydrated uranium peroxide, dried at 100°, is a yellowish-white powder; decomposed by heat, giving off O and leaving much U_3O_8; reacts with alkali solutions to give $UO_3.xH_2O$, and a solution from which alkali *peruranate* $2M_2O.UO_6.8aq$, crystallises (Fairley, *l.c.*; *v. Peruranates* under Uranium oxyacids, and salts thereof, p. 827).

Uranium oxyacids, and salts thereof. $UO_3.H_2O = H_2UO_4$ reacts with strong bases as an acid, forming uranates $M^I_2UO_4$; di-uranates $M^I_2U_2O_7$ are also known, and a few tri- and hexa-uranates. A few peruranates are derived from hydrated uranium peroxide $UO_4.xH_2O$. The compounds of UO_2X_2 with MX (X = Br, Cl, or F) may be regarded as bromoxy-, chloroxy-, and fluoxy-uranates. The substance known as *uranium red* is perhaps $UO_2.ONH_4.SNH_4$, *i.e.* the ammonium salt of an oxythio-uranic acid (*v.* Uranium oxysulphides, p. 828).

Uranic acid H_2UO_4. This compound is obtained as a yellow powder, which reddens litmus paper, and is decomposed to UO_3 and H_2O at 250°–300°, and to U_3O_8 and O at a higher temperature, by boiling a solution of $UO_2(NO_3)_2$ in absolute alcohol, washing the solid that separates with water, and drying in air or *in vacuo*. (For other methods of preparation, and more details *v.* Hydrates of uranium trioxide, p. 825.) The salts of H_2UO_4 are prepared indirectly.

Uranates, di-uranates, &c. Salts derived from H_2UO_4; salts derived from the hypothetical acids $H_2U_2O_7$, $H_2U_3O_{10}$, $H_2U_6O_{19}$ are also known.

URANATES. Salts of the composition $M^I_2UO_4$ and $M^{II}UO_4$. These salts are prepared by ppg. solutions of uranyl salts by bases in solution, or by adding alkali solution to a mixture of a uranyl salt and a metallic oxide in solution; also, in many cases, by oxidising U_3O_8 or UO_2 in presence of a base or a salt of a base. The uranates are insoluble in water, and are not readily decomposed by heat except the ammonium salt. Carson a. Norton (*Am.* 10, 219) have pointed out that analyses of uranates always show considerable differences between the percentages of U found and calculated; they have found the same anomaly in analyses of uranates of ammonium and several ammonium derivatives, such as $NEtH_3$, NEt_2H_2, &c.

Ammonium uranates. The pure salt does not seem to have been isolated. An impure uranate containing c. 90 p.c. UO_3 ($(NH_4)_2UO_4$ requires 84·66 p.c. UO_3) is obtained by adding NH_3Aq to a solution of a uranyl salt (Péligot); it is a yellow powder, which loses H_2O and NH_3 above 100°, very slightly soluble in water, and insol. NH_3Aq (Arfvedson, *P.* 1, 245). An impure salt is also obtained by adding NH_4ClAq or $(NH_4)_2SO_4Aq$ to boiling Na_2UO_4Aq, as long as NH_3 and CO_2 are given off, washing the pp., and drying at a low temperature (Anthon, *D. P. J.* 156, 211). Heated to redness gives U_3O_8; many of the compounds of U are prepared from ammonium uranate.

Potassium uranate K_2UO_4. Prepared by heating 6 g. U_3O_8 with $HClAq$ and HNO_3Aq, adding 4 g. KCl and 16 g. NH_4Cl, evaporating to dryness, heating very strongly until the fused mass is orange-yellow, and washing with water (Zimmermann, *A.* 213, 290). The salt is said to be formed also by strongly heating UO_2HPO_4 (obtained by ppg. a uranyl salt by a phosphate) with K_2SO_4 (Grandeau, *A. Ch.* [6] 8, 223). Orange-yellow, rhombic tablets; insol. water, cold or hot; easily sol. acids (Zimmermann, *l.c.*).

Sodium uranate Na_2UO_4. Prepared by fusing U_3O_8 with NaCl and Na_2CO_3, or with NaCl with gradual addition of $NaClO_3$, and washing with water; resembles K_2UO_4 (Zimmermann, *l.c.*).

Lithium uranate Li_2UO_4 has been prepared similarly to K_2UO_4; it is said to be decomposed by hot water (Z., *l.c.*). Uranates of Ba, Ca, and Sr—MUO_4—are said by Ditte (*C. R.* 95, 988) to be formed by heating the chlorides of these metals with U_3O_8.

DI-URANATES. Salts of the composition $M^I_2U_2O_7$ and $M^{II}U_2O_7$. The formulæ may also be written $M^I_2UO_4.UO_3$ and $M^{II}UO_4.UO_3$.

Barium di-uranate BaU_2O_7. Formed by ppg. $UO_2(C_2H_3O_2)_2Aq$ by BaOAq (Berzelius, *P.* 1, 359); also by heating to redness $UO_2.Ba(C_2H_3O_2)_4$ (Wertheim, *J. pr.* 29, 207). A yellowish-red powder.

Calcium di-uranate CaU_2O_7. Formed, according to Ditte (*C. R.* 95, 988), by strongly heating U_3O_8 with $Ca(ClO_3)_2$; a yellowish-green solid.

Copper di-uranate CuU_2O_7. This salt is said to be formed, as a green crystalline powder, by fusing $Cu(UO_2.PO_4)_2.8aq$, with Na_2CO_3, and washing with water (Debray, *A. Ch.* [8] 61, 451).

Lead di-uranate PbU_2O_7. Formed by digesting $UO_2(C_2H_3O_2)_2Aq$ with freshly ppd. $PbCO_3$ (Wertheim, *J. pr.* 29, 207); also by adding NH_3Aq to a mixture of $UO_2(NO_3)_2Aq$ and $Pb(NO_3)_2Aq$ (Arfvedson, *P.* 1, 258). A yellowish-red powder, becoming green when heated; strongly heated in H, gives a pyrophoric mixture of Pb and UO_2.

Potassium di-uranate $K_2U_2O_7$. Formed by melting together UO_3 and K_2CO_3 and washing with water; also by strongly heating $UO_2.K_2(CO_3)_2$ or $UO_2.K(C_2H_3O_2)_3$ (Berzelius, *P.* 1, 359). A yellowish-red powder.

Silver di-uranate $Ag_2U_2O_7$. Obtained by adding amorphous K_2UO_4 to molten $AgNO_3$, and washing with ice-cold water (Alibegoff, *A.* 232, 129; 233, 117, 143). Also by strongly heating $UO_2.Ag(C_2H_3O_2)_3$ (Wertheim, *J. pr.* 29, 221; *cf.* Rammelsberg, *P.* 59, 10). An amorphous, yellow-red solid; easily sol. acids; decomposed by hot water (Alibegoff, *l.c.*).

Sodium di-uranate $Na_2U_2O_7$. 6aq. Obtained by ppg. uranyl salts by NaOHAq (Patera, *J. pr.* 51, 125; *cf.* Stolba, *Fr.* 3, 74). Loses water of crystallisation over H_2SO_4. A light-yellow to darkish-yellow powder. Known commercially as *uranium yellow* (*v.* DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 893).

Di-uranate of strontium SrU_2O_7 is said also to exist (Ditte, *C. R.* 95, 988).

TRI-URANATES. The only salt that has been isolated is *sodium tri-uranate* $Na_2U_3O_{10}$; it is prepared by fusing $UO_2(SO_4)$ with NaCl, and boiling out with water. This salt forms yellow leaflets resembling mosaic gold; S.G. 6·912; hygroscopic; insol. water, sol. acids (Drenkmann, *J.* 1861. 255).

HEXA-URANATES. The *potassium salt*, $K_2U_6O_{19}$. 6aq, is described as a yellow microscopically crystalline powder, which loses all water at 300°–400°; prepared by melting $UO_2(SO_4)$ with KCl (Drenkmann, *J.* 1861. 255).

PER-URANATES. By adding excess of alkali and H_2O_2Aq to solutions of uranyl salts, Fairley (*C. J.* 31, 134) obtained salts which may be formulated as $M^I{}_4UO_8$. $x$aq and $M^I{}_2R^{II}UO_8$. $x$aq where $M = NH_4$, K, or Na, and $R = UO_2$.

Ammonium-uranyl peruranate $(NH_4)_2(UO_2)UO_8$. 8aq. The formula may also be written $(NH_4)_2O.U_2O_9$. 8aq, or $(NH_4)_2O.UO_3.UO_6$. 8aq, or, regarding the compound as a double peroxide of U and NH_4, as $2UO_4.(NH_4)_2O_2$.8aq. The salt is prepared by adding excess of NH_3Aq and H_2O_2Aq to a solution of a uranyl salt and ppg. by alcohol; it is an orange-yellow solid, readily soluble in water. The quantity of $KMnO_4$ in solution decolourised shows that the ratio of U to 'peroxide oxygen' in the salt is U:3O.

Potassium per-uranate K_4UO_8. 10aq. This salt may also be looked on as a double peroxide of U and K ($UO_4.K_4O_4$.10aq), or as $2K_2O.UO_6$. 10aq. It is prepared by adding alcohol to a solution obtained by treating $UO_2(NO_3)_2$Aq with KOHAq and excess of H_2O_2Aq, and rapidly drying the orange-yellow pp. by pressure in filter paper. The salt rapidly absorbs CO_2 from the air and loses O; it is easily decomposed by heat, giving off H_2O and O. Experiments showed that the ratio of U to 'peroxide oxygen' is U:3O.

Sodium peruranate Na_4UO_8. 8aq. The formula may also be written $UO_4.Na_4O_4$. 8aq or $2Na_2O.UO_6$. 8aq. The salt is prepared by dissolving 'ordinary uranic hydrate,' or UO_4. $x$aq, in excess of NaOHAq along with excess of H_2O_2Aq, allowing to crystallise if conc. solutions are used, or ppg. by a little alcohol if dilute solutions are used, and drying by pressure in filter paper. Poleck (*B.* 27, 1051 [1894]) obtained this salt by adding sodium superoxide to solution of a salt of U. The salt is golden-yellow and lustrous; it slowly absorbs CO_2 from the air, and gives off O. When heated, alone or in CO_2, it gives off 3O; it also loses 3O in contact with acidified $KMnO_4$Aq or other unstable O compounds. The ratio of U to 'peroxide oxygen' is U:3O as measured by the quantity of $KMnO_4$ decolourised by a solution of the salt.

Sodium-uranyl per-uranate $Na_2(UO_2)UO_8$. 6aq. The formula may also be written $Na_2O.U_2O_9$. 6aq or $Na_2O.UO_3.UO_6$. 6aq; or, regarding the compound as a double peroxide of U and Na, as $2UO_4.Na_2O_2$. 6aq. The salt is prepared similarly to Na_4UO_8. 8aq, but using only the minimum quantity of NaOHAq required for solution, and adding alcohol, when it separates as a red oil which slowly crystallises to a red solid. The quantity of $KMnO_4$ in solution decolourised by a solution of the salt showed that the ratio of U to 'peroxide oxygen' is U:3O.

Uranium, oxybromide of, UO_2Br_2. (*Uranyl bromide.*) In preparing UBr_4, by heating a mixture of U_3O_8 and C in Br vapour, Hermann (*J.* 1861. 260) obtained a yellow, easily volatile sublimate, which was probably an oxybromide. By heating UO_2 with Br and water, also by dissolving UO_3 in HBrAq, a colourless liquid is obtained, which on evaporation gives yellow needles of the *hydrated oxybromide* UO_2Br_2. 7aq (Sendtner, *A.* 195, 325). This compound combines with NH_4Br and KBr to form $UO_2Br_2.2MBr$ (*v.* URANOXYBROMIDES, p. 822).

Uranium, oxychloride of, UO_2Cl_2. (*Uranyl chloride.*) Formed by strongly heating UO_2 in Cl; a yellow, crystalline solid, easily fused, but volatilised only at a high temperature; heated with K forms UO_2 and KCl (Péligot, *A. Ch.* [3] 5, 5). By dissolving $UO_3.H_2O$ in HClAq, also by oxidising UCl_4 by HNO_3Aq, and evaporating, yellowish-green crystals of $UO_2Cl_2.xH_2O$ are obtained (Klaproth, *Crell's A.* 1789 [2]. 387).

By dissolving UO_2Cl_2 in ether and evaporating, Regelsberger (*A.* 227, 119) obtained yellow needles of the compound $UO_2Cl_2.2Et_2O$.

UO_2Cl_2 forms compounds with NH_4Cl and KCl of the form $2MCl.UO_2Cl_2$ (*v.* URANOXYCHLORIDES, p. 823).

UO_2Cl_2 combines with NH_3 to form $UO_2Cl_2.xNH_3$, where $x = 2$, 3, and 4. The first of these compounds, $UO_2Cl_2.2NH_3$, is formed by passing dry NH_3 into UO_2Cl_2 dissolved in ether, drying the voluminous yellow pp. that forms, and then placing it *in vacuo* over H_2SO_4 until all ether is removed; the second compound, $UO_2Cl_2.3NH_3$, is formed by the action of NH_3 on $UO_2Cl_2.2NH_3$; and a mixture of $UO_2Cl_2.3NH_3$ and $UO_2Cl_2.4NH_3$ is produced by passing NH_3 over solid UO_2Cl_2. When strongly heated in air these compounds give off all NH_3 and Cl and leave U_3O_8; heated out of contact with air they give UO_2 (Regelsberger, *A.* 227, 119). The three compounds are called by R. *uranylammonium chlorides*, and their formulæ are written $UO_2(NH_3Cl)_2$, $UO_2(NH_3Cl)(NH_2.NH_3Cl)$, and $UO_2(NH_2.NH_3Cl)_2$. Water reacts thus:—

(1) $3UO_2(NH_3Cl)_2 + 3H_2O =$
$(NH_4)_2U_2O_7 + UO_2Cl_2 + 4NH_4Cl$;

(2) $UO_2(NH_4Cl)_2 + 2H_2O = UO_2(OH)_2 + 2NH_4Cl$; the second reaction takes place quickly with warm water.

Uranium, oxyfluoride of, UO_2F_2. (*Uranyl fluoride.*) This compound is produced by boiling U_3O_8 with HFAq, filtering off UF_4 (*v.* URANIUM TETRAFLUORIDE, p. 823), and evaporating the filtrate; it is also formed, in small quantities, by heating UF_4 in a closed Pt crucible. The compound differs according to the method of preparation (Smithells, *C. J.* 43, 125).

a-Oxyfluoride. About 1 gram UF_4 is heated in a Pt crucible with the lid on, temperature being raised as quickly as possible; after five minutes the crucible is allowed to cool, the light, bulky sublimate is removed, and the crucible is again heated for five minutes, and these processes are repeated several times (S., *l.c.* p. 129). This form of UO_2F_2 is a very bulky, light, white, crystalline solid; it is very soluble in water, forming a yellow liquid; heated in air it is gradually changed to U_3O_8.

β-Oxyfluoride. U_3O_8 is treated with boiling HFAq in a leaden vessel, the yellow solution is poured off from green UF_4, heated until the excess of HF is driven off, and allowed to evaporate; evaporation may be completed over H_2SO_4 and CaO *in vacuo*; the residue is dried at 100° (S., *l.c.* p. 130). This form of UO_2F_2 is a yellow saponaceous mass; in one instance the preparation had a semi-crystalline appearance, forming yellow, lustrous scales; it is very soluble in water or alcohol; heated on Pt foil U_3O_8 is formed; heated in a closed crucible it is slowly decomposed, giving UO_2. β-UO_2F_2 probably forms a compound with HF; by evaporating a solution of U_3O_8 in HFAq over H_2SO_4 and CaO until the weight was constant, Smithells (*l.c.* p. 131) obtained a substance which gave results on analyses agreeing fairly with the formula $UO_2F_2.HF.H_2O$.

A solution in water of either form of UO_2F_2 mixed with KFAq and KHF_2Aq, and evaporated, gives the quadratic fluoxy-uranate $K_3UO_2F_5$ (S., *l.c.* p. 130–1). For the compounds of UO_2F_2 with MF *v.* URANOXYFLUORIDES (p. 824).

Ditte (*C. R.* 91, 115) gave the formula UOF_4 to the sublimate obtained by heating, in a closed Pt crucible, the solid that remained when U_3O_8 was treated with boiling HFAq. Ditte said that this solid was UO_2F_2; Smithells (*l.c.*) has, however, shown that the solid obtained by the method used by Ditte is UF_4, and that the sublimate formed by heating this is a-UO_2F_2.

Uranium, oxysulphides of. Two compounds probably exist.

URANIUM OXYSULPHIDE $U_2O_2S_4$. This composition was given by Hermann (*J.* 1861. 258) to a dark, greyish-black solid, obtained by heating UO_2, U_3O_8, or NH_4 uranate to redness in vapour of CS_2. Dissolves in conc. HClAq; burns when heated in air (*cf.* H. Rose, *G. A.* 73, 139).

URANYL SULPHIDE $(UO_2)S$. A brown solid, obtained by ppg. an ammoniacal solution of a uranyl salt by cold $(NH_4)_2SAq$, and quickly washing with conc. alcohol. Probably not obtained pure, as it quickly decomposes; water produces $UO_3.xH_2O$; at 40°–50° it is changed to UO_2 and S (Remelé, *P.* 124, 114; Zimmermann, *A.* 204, 204). $(UO_2)S$ is somewhat sol. water or dilute alcohol; dissolved by conc. HClAq, giving UCl_4 and S; dissolved by $(NH_4)_2SAq$, only in presence of $(NH_4)_2CO_3Aq$ (Zimmermann, *l.c.*), forming a brown liquid.

Uranium black. By allowing $(UO_2)S$ to stand in contact with freshly prepared $(NH_4)_2SAq$, in absence of air, a dull black amorphous powder is obtained. This solid dissolves in mineral acids, giving off traces of H_2S; it dissolves partly in warm $(NH_4)_2CO_3Aq$, but not in warm $(NH_4)_2SAq$, nor in caustic alkali solutions; heated in a tube to c. 270° it gives off a very little NH_3 and H_2O. Zimmermann (*A.* 204, 204) gives the formula U_7O_{10} to uranium black, neglecting (as impurities) the traces of NH_3 and S which the substance contains.

Uranium red. By allowing $(UO_2)S$ to stand for 24–48 hours in contact with cold $(NH_4)_2SAq$, exposed to air, a deep-red solid is obtained; soluble in dilute mineral acids, with separation of S and evolution of H_2S; gives off NH_3, S, and H_2O when heated to 150° and, at above 200°, leaves U_3O_8 (Zimmermann, *l.c.*). According to Z., the formation of this red substance takes place only when $(NH_4)_2S_2O_3$ is present in the $(NH_4)_2SAq$ used; $(NH_4)_2S_2O_3$ is formed by the action of the air. Z. gives to uranium red the composition $U_5S(NH_4)_2O_9 = UO_2.ONH_4.SNH_4.2U_2O_3$ (*cf.* Patera, *J. pr.* 51, 122; Remelé, *P.* 124, 158; Hermann, *J.* 1861. 14).

Uranium, salts of. Two classes of salts are formed by treating oxides of U with acids; UO_2 forms corresponding salts, UX_2 when X = the radicle of a dibasic acid, and UX_4 when X = the radicle of a monobasic acid; UO_3 forms salts $(UO_2)X$ when X = the radicle of a dibasic acid, and $(UO_2)X_2$ when X = the radicle of a monobasic acid. The salts UX^I_4 and UX^{II}_2 are called *uranous salts*; and $(UO_2)X^I_2$ and $(UO_2)X^{II}$ are called *uranyl salts*. (For reactions of the two classes of salts *v.* URANIUM, *Detection and estimation* of, p. 822.) Besides the normal salts, a large number of basic salts of both classes is known, and also many double salts.

The chief *uranous salts* are *arsenates*, *phosphates*, and *sulphites*. The chief *uranyl salts* are *arsenates*, *bromate*, *double carbonates*, *chromates*, *hypophosphite*, *iodate*, *nitrates*, *oxalate*, *phosphates*, *phosphite*, *selenates*, *selenites*, *sulphates*, and *sulphites* (*v.* NITRATES, SULPHATES, &c.).

Uranium, sulphides of. When U is burnt in vapour of S, the disulphide US_2 is formed; by passing H_2S over heated UBr_3 the sesquisulphide U_2S_3 is produced; and by heating U_2S_3 in H the monosulphide US is obtained. The mol. w. of none of these is known.

URANIUM DISULPHIDE US_2. Prepared by heating U in vapour of S (Péligot, *P.* 54, 122; *cf.* Zimmermann, *A.* 216, 18); also by heating UCl_4 to redness in H_2S (Hermann, *J.* 1861. 258). A dark greyish-black powder; becomes crystalline when fused with borax; oxidises slowly in air, rapidly on heating. Easily soluble in conc. HClAq (Hermann, *l.c.*).

URANIUM SESQUISULPHIDE U_2S_3. A stream of dry H_2S, perfectly free from air, is passed over heated UBr_3 as long as HBr is given off. Grey-black solid, forming pseudomorphs of UBr_3; decomposes in air, giving off H_2S; burns when heated in air; scarcely acted on by HClAq or dilute HNO_3Aq; decomposed violently by conc. HNO_3 (Alibegoff, *A.* 233, 117).

Uranium monosulphide US. A black, amorphous powder; obtained by passing dry H over U_2S_3, kept at a red heat, for c. 40 hours, until H_2S is no longer given off. Similar in properties to U_2S_3 (Alibegoff, *A.* 233, 135).

Uranium thio-acids, salts of. No thio- acid, nor salt of a thio- acid, of U has been definitely isolated. *Uranium red* (*v. supra*, p. 828) may perhaps be an ammonium oxythionate of U.

M. M. P. M.

URANOXYBROMIDES *v.* p. 822, under Uranium tetrabromide.

URANOXYCHLORIDES *v.* p. 823, under Uranium tetrachloride.

URANOXYFLUORIDES *v.* p. 824, under Uranium tetrafluoride.

URANYL COMPOUNDS, compounds of the radicle UO_2; *v.* Uranyl ammonium chlorides (p. 827), Uranyl bromide (p. 827), Uranyl chloride (p. 827), Uranyl fluoride (p. 828), Uranyl salts (p. 828), Uranyl sulphide (p. 828).

URAZOLE. A name given by Pinner (*B.* 20, 2358) to di-oxy-triazole, which may be represented as $\begin{matrix}NH.C(OH)\\ N{=}C(OH)\end{matrix}\!\!\geqslant\!N$ or $\begin{matrix}NH.CO\\ NH.CO\end{matrix}\!\!>\!NH$.

UREA CH_4N_2O, *i.e.* $CO(NH_2)_2$. *Carbamide.* Mol. w. 60. [132°] (Lubavin, *B.* 3, 305). S.G. 1·323 (Schröder, *B.* 12, 562). S. (alcohol) 20 in the cold; 100 at 78°. H.C.v. 152,500. H.C.p. 152,200 (Stohmann a. Langbein, *J. pr.* [2] 44, 387); 160,900 (Berthelot a. Petit, *C. R.* 109, 759; 110, 887). H.F. 80,800.

Occurrence.—In the urine of mammalia, especially in that of flesh-eaters (Fourcroy a. Vauquelin, *A. D.* 1799). Occurs in small quantity in blood, muscle, chyle, and lymph of mammalia (Wurtz, *C. R.* 49, 52; Poisseuille a. Gobley, *J.* 1859, 612; Verdeil a. Dollfus, *A.* 74, 214; Munk, *Pf.* 11, 100; Pickard, *C. R.* 83, 1179; 87, 533; Gréhant a. Quinquand, *C. R.* 108, 1092; Garrod, *Pr.* 53, 478). Constitutes about 30 p.c. of the solid substance of the vitreous humour of the eye (Millon, *C. R.* 26, 119; *A.* 66, 128). Occurs also in saliva (Rabuteau, *J.* 1873, 877), in cow's milk (Lefort, *Z.* 1866, 190; Vogel, *J.* 1867, 932), and in other animal secretions.

Formation.—1. By evaporating a solution of ammonium cyanate (Liebig a. Wöhler [1828], *B. J.* 12, 266; *P.* 12, 253; 15, 619; *A.* 38, 108). 2. By adding a little NHO_3 to an ethereal solution of cyanamide (Cannizzaro a. Cloëz, *A.* 78, 230) or by the action of dilute (50 p.c.) H_2SO_4 on cyanamide (Baumann, *B.* 6, 1373).—3. From $COCl_2$ and dry NH_3 (Regnault, *A. Ch.* [2] 69, 180; Natanson, *A.* 98, 287), guanidine and NH_4Cl being formed at the same time (Fenton, *C. J.* 35, 793).—4. By heating carbonic ether with NH_3Aq at 180°.—5. By heating ammonium carbamate at 140° (Basaroff, *J. pr.* [2] 1, 283).—6. By passing an alternating electric current through a solution of ammonium carbamate (Drechsel, *J. pr.* [2] 22, 481).—7. By electrolysis of ammonia solution using carbon electrodes (Millot, *Bl.* [2] 46, 243).—8. By passing a mixture of NH_3 and CO_2 through a red-hot tube (Dexter, *Am.* 4, 35).—9. Formed by passing air charged with NH_3 and vapour of benzene over a red-hot helix of platinum wire (Herroun, *C. J.* 39, 471). Acetylene, but not ethylene, may be substituted for benzene.—10. By heating ammonium thiocarbamate $NH_2.CO.SNH_4$, or by shaking it with water and $PbCO_3$.—11. By the action of aqueous $KMnO_4$ on thio-urea (Maly, *M.* 11, 277).—12. By the action of $KMnO_4$ on KCy in acid solution (Baudrimont, *J.* 1880, 393).—13. By the action of NH_3Aq and H_2S on copper fulminate (Gladstone, *A.* 66, 2).—14. By heating oxamide with HgO (Williamson, *Mémoires du Congrès scientif. de Venise*, A.D. 1847).—15. By oxidation of uric acid.—16. By the action of $KClO_3$ and HCl on guanine (Strecker, *A.* 118, 159).—17. By boiling guanidine with baryta (Baumann, *B.* 6, 1376).—18. By boiling biguanide sulphate or phenyl-biguanide sulphate with baryta (Emich, *M.* 12, 11).—19. By the action of baryta on arginin (Schulze a. Likiernik, *B.* 24, 2701).—20. By boiling creatin with baryta.—21. A product of oxidation of proteïds by $KMnO_4$ (Béchamp, *A. Ch.* [3] 48, 348; *C. R.* 70, 866; Ritter, *Bl.* [2] 16, 32). Staedeler (*J. pr.* 72, 251) and Loew (*J. pr.* [2] 2, 289) failed to obtain urea in this manner. Dreschel (*B.* 23, 3097) obtained urea from albumen by electrolysis, but not by oxidation.

Preparation.—1. Urine, concentrated by evaporation, is treated with nitric or oxalic acid, and the ppd. nitrate or oxalate of urea is decomposed by $CaCO_3$.—2. A solution of potassium cyanate mixed with ammonium sulphate is evaporated on a water-bath to dryness, and the residue extracted with alcohol.—3. A mixture of dry K_4FeCy_6 (28 pts.) and MnO_2 (14 pts.) is heated till sticky on an iron plate. A cold aqueous extract of the mass is mixed with $(NH_4)_2SO_4$ (20·5 pts.), evaporated to dryness, and extracted with alcohol (Liebig).—4. Dry K_4FeCy_6 (8 pts.) is fused with K_2CO_3 (3 pts.) and PbO (15 pts.) added to the melted mass. The cooled mixture is dissolved in water, mixed with $(NH_4)_2SO_4$ (8 pts.) evaporated, and extracted with alcohol (Clemm, *A.* 66, 382). Any K_4FeCy_6 left can be removed by $FeSO_4$.—5. Lead cyanate is digested with $(NH_4)_2SO_4$ (J. Williams, *C. J.* 21, 64).—6. From NH_3Aq, COS, and lead carbonate (Schmidt, *B.* 10, 193).—7. By the action of $(NH_4)_2SO_4$ on KCyO obtained by heating dry K_4FeCy_6 with $K_2Cr_2O_7$; the yield being 25 p.c. of the weight of ferrocyanide (C. A. Bell, *C. N.* 32, 99).—8. A stream of dry NH_3 gas is passed through phenyl-carbonate (from phenol-sodium and $COCl_2$), melted in a water-bath, and the melt is then poured into hot water; the aqueous solution after separation from the phenol is evaporated to crystallisation (Hentschel, *B.* 17, 1286).

Properties.—Dimetric crystals, v. e. sol. water, m. sol. cold alcohol, insol. $CHCl_3$, nearly insol. ether. Sublimes at 130°. *In vacuo* it distils at 135° (Bourgeois, *Bl.* [3] 7, 45). Urea is not attacked by pure HNO_3 (Franchimont, *R. T. C.* 6, 217).

Reactions.—1. When heated alone at 150°–170° it yields NH_3, cyanuric acid and biuret; at 140° it yields ammelide.—2. Decomposed into CO_2 and NH_3 by heating with water in sealed tubes above 100°, by boiling with potash, lime, or magnesia, by warming with conc. H_2SO_4, by evaporating with lead acetate, and by the action of ozone (Gorup-Besanez, *A.* 125, 207) in presence of free alkali. CaO produces cyanamide (Emich, *M.* 10, 330). A 8 p.c. HCl solution decomposes 4 p.c. of the urea in 24 hours. NaOHAq of the same strength has less effect. Cold water does not decompose urea (Berthelot a. André, *Bl.* [2] 47, 840).—3. *Alcoholic potash* forms, on heating in sealed tubes, cyanic acid, NH_3, and water (Haller, *Bl.* [2] 45, 705).—4. Urea hydrochloride at 145° yields NH_4Cl and cyanuric acid (De Vry, *A.* 61, 249).—5. *Chlorine* passed over melted urea forms HCl, nitrogen, NH_4Cl, and cyanuric acid (Wurtz, *A.* 64, 307).—6. *Hypochlorous acid, hypochlorites, chlorine-water*, and *hypobromites*, set free nitrogen, *e.g.* $CON_2H_4 + 3HOCl = CO_2 + 3HCl + 2H_2O + N_2$.—7. *Nitrous acid* added to a hot solution forms CO_2 and nitrogen: $CON_2H_4 + N_2O_3 = CO_2 + 2H_2O + 2N_2$. Nitrous acid (2 mols.) when added to a cold solution of urea (1 mol.) reacts as follows: $2CON_2H_4 + N_2O_3 = (NH_4)_2CO_3 + 2N_2 + CO_2$ (Claus, *B.* 4, 140).—8. Neutral $KMnO_4$ has no action in the cold, and acts but slowly at 100°. In acid solutions $KMnO_4$ gives off nitrogen (1 vol.) and CO_2 (2 vols.) (Béchamp, *J.* 1856, 696; *cf.* Wanklyn a. Gamgee, *C. J.* 21, 25).—9. *Bromine* added gradually to an alcoholic solution of urea forms NH_4Br, cyanuric acid, and nitrogen. In sealed tubes Br gives NH_4Br and cyamelide (Smolka, *M.* 8, 64).—10. Heating with P_2O_5 forms cyanic and cyanuric acids, ammelide, cyamelide, and NH_3 (Weltzien, *A.* 107, 219).—11. Yields cyanamide on warming with Na (Fenton, *C. J.* 41, 262).—12. Conc. HNO_3 reacts thus: $CON_2H_4 + 2HNO_3 = CO_2 + N_2O + NH_4NO_3 + H_2O$ (Franchimont, *R. T. C.* 2, 96; 3, 219).—13. P_2S_5 forms crystalline $C_2H_8N_3PS_2O_2$, which yields $C_2H_7AgN_3PS_2O_2$ and $C_2H_5Ag_3N_3PS_2O_2$, and gives off PH_3 on warming (Kutschig, *M.* 9, 406).—14. *Zinc-dust* at a red heat forms $ZnCy_2$, ammonia, and hydrogen (Aufschläger, *M.* 13, 272). 15. CS_2 at 100° forms COS and ammonium sulphocyanide. With alcohol and CS_2 the products are mercaptan, CO_2, and ammonium sulphocyanide (Ladenburg, *Z.* [2] 5, 253; *B.* 1, 273; 2, 271; Fleury, *A.* 123, 144).—16. *Alcohols* in sealed tubes form carbamic ethers and alkyl allophanates (Cahours, *C. R.* 76, 1387).—17. Boiling Ac_2O forms acetamide and diacetamide (Hofmann, *B.* 14, 2733).—18. $ZnEt_2$ forms CON_2H_2Zn, which is reconverted into urea by water (Gal, *Bl.* [2] 39, 648).—19. *Oxalic ether* at 135°-170° forms oxamide, allophanic ether, and alcohol (Grabowski, *A.* 134, 115). *Oxamic ether* forms, on fusion, oxaluramide (Carstanjen, *J. pr.* [2] 9, 143).—20. *Methylamido-acetic acid* (sarcosine) forms methyl-hydantoïn on fusion (Huppert, *B.* 6, 1278).—21. *Aniline* at 150°-170° gives NH_3 and di-phenyl-urea (Baeyer, *A.* 131, 251).—22. *Aniline sulphonic acid* at 120° gives $NH_2.CO.NH.C_6H_4.SO_3H$ (Ville, *Bl.* [3] 6, 6).—23. *Biguanide sulphate* forms, on heating, ammeline, NH_3 and $(NH_4)_2SO_4$ (Smolka a. Friedreich, *M.* 10, 95).—24. Heated with *acetone* and $ZnCl_2$ or P_2O_5 at 110°-140° it gives *s*-tri-methyl-pyridine and a base $C_{18}H_{19}N$ [119°]; (320°) (Riehm, *A.* 238, 22). This base forms hard monoclinic crystals, with metallic ring; its solutions fluoresce. It gives $B'_2H_2PtCl_6$: [225°].—25. Heated with *acetyl-acetone* (1 mol.), urea (2 mols.) forms $CH_2(CMe:N.CO.NH_2)_2$, which crystallises from alcohol [200°] (Combes, *Bl.* [3] 7, 790). The same body is formed, together with $CH_2{<}\begin{smallmatrix}CMe:N\\CMe:N\end{smallmatrix}{>}CO$ [198°], by adding HClAq or H_2SO_4 to an alcoholic solution of urea and acetyl-acetone (Evans, *J. pr.* [2] 46, 352; 48, 499).—26. *Benzoyl-acetone* forms, in like manner, $Bz.CH_2.CMe:N.CO.NH_2$ [191°] and $CH_2{<}\begin{smallmatrix}CMe:N\\CPh:N\end{smallmatrix}{>}CO$ [227°] (Evans, *J. pr.* [2] 46, 352; 48, 509).—27. *Acetoacetic ether* (2 mols.) and NaOEt (2 mols.) form in the cold $C_{13}H_{22}N_2O_7Na_2$ [c. 165°] (Ernert, *A.* 258, 361). Acetoacetic ether in alcoholic solution forms uramido-crotonic acid (*q. v.*).—28. *Urea* reacts with aldehydes in the cold. In aqueous solution a diureïde $R.CH(NH.CO.NH_2)_2$ is usually formed, while solid urea forms triureïdes. On warming with excess of aldehyde, di- and tri-ureïdes yield tetra- and hexa-ureïdes (H. Schiff, *A.* 151, 186). These ureïdes are sparingly soluble neutral solids, and are split up by warming with acids into the parent substances. Benzoic aldehyde forms benzylidene-di-urea (*q. v.*), while *o*-oxy-benzoic aldehyde forms $C_6H_4(OH).CH(NH.CO.NH_2)_2aq$, which is converted by acetoacetic ether in alcohol into $C_6H_4(OH).CH:N.CO.N:CMe.CH_2.CO_2Et$ [200°], $C_6H_4(OH).CH:N.CO.NH.CMe:CH.CO_2Et$ [204°], and $C_6H_4{<}\begin{smallmatrix}CH:N.CO\\O.CH:CMe\end{smallmatrix}{>}NH$, which decomposes between 260° and 270° (Biginelli, *B.* 24, 2963). Acroleïn forms $(CON_2H_4)_2 3C_3H_4O$, which chars at 250° (Lüdy, *M.* 10, 295). *o*-Nitro-benzoic aldehyde forms nitro-benzylidene-di-urea $C_6H_4(NO_2).CH(NH.CO.NH_2)_2$ aq [200°]. In like manner cuminic aldehyde in alcohol forms the di-ureïde $C_3H_7.C_6H_4.CH(NH.CO.NH_2)_2$ [176°] (Biginelli, *B.* 24, 2964), and cinnamic aldehyde forms $Ph.CH:CH.CH(NH.CO.NH_2)_2$ [172°], and compounds melting at 116° and 212°.—29. *Chloral* added to conc. aqueous solutions of urea forms $(C_2HCl_3O)CON_2H_4$ [150°], v. e. sol. hot water, and $(C_2HCl_3O)_2CON_2H_4$ [190°] nearly insol. hot water, both compounds being crystalline (Jacobsen, *A.* 157, 246). Chloral cyanhydrin at 105° forms the very stable crystalline $C_3H_3Cl_2N_3O$ (Pinner a. Fuchs, *B.* 10, 1069).—30. *Benzene sulphonic chloride* at 100° forms colourless crystals of $C_6H_5SON_4H_7C_2O_2$ aq (Elander, *Bl.* [2] 34, 207). Naphthalene (α)-sulphonic chloride acts similarly.—31. *Cinnamoyl chloride* forms $C.H_8(NH.CO.NH.C_9H_8.NH.CO.NH_2)_2$ [184°] (Biginelli, *B.* 24, 2965).—32. $ClCH_2.OH$ forms methylene-urea, which is split up by hot dilute H_2SO_4 into formic aldehyde and urea (Von Hemmelmayr, *M.* 12, 89).—33. *Trichlorolactic acid* and a little water form, on heating, acetylene-urea $C_4H_6N_4O_2$ (Pinner, *B.* 17, 1997).—34. *Hexa-chloro-acetone* (2 mols.) heated with urea (1 mol.) at 150° forms $CO:N_2H_2(C_2Cl_3O)_2$, crystallising from alcohol in hexagonal plates (Cloëz, *A. Ch.* [6] 9, 145).

Detection.—Urea gives, in conc. solution, crystalline pps. with nitric and oxalic acids. Urea dissolved in amyl alcohol is completely ppd. by an ethereal solution of oxalic acid (Brücke, *M.* 3, 195). Musculus (*C. R.* 78, 132) filters putrid urine, dries the filter at 35°, and employs it as a test for urea, which it converts into ammonium carbonate. A conc. aqueous solution of furfuraldehyde followed by a drop of HClAq (S.G. 1·10) colours a crystal of urea violet (Schiff, *B.* 10, 774). *o*-Nitro-benzoic aldehyde added to an alcoholic solution of urea forms, on warming, a white pp. of *o*-nitro-benzylidene-di-urea [200°]. When present in small quantities this compound may be detected by resolving into the parent substances by boiling with very dilute H_2SO_4, and then adding a little phenylhydrazine solution, which produces a red colour (Lüdy, *M.* 10, 295). Mercuric nitrate gives a white pp. with solutions of urea. The various methods of estimating urea may also be employed for its detection.

Estimation. — Hypobromite method. Urea is mixed with NaOH (100 g. in 250 c.c. water) to which bromine (25 g.) has been added, and the nitrogen collected and measured (Knop, *Fr.* 9, 226; Hüfner, *J. pr.* [2] 3, 1; Dupré, *C. J.* 31, 534; Simpson a. O'Keefe, *C. J.* 31, 838; Russell a. West, *C. J.* 27, 749; Eykman, *R. T. C.* 3, 125; Schleich, *J. pr.* [2] 10, 263; Colquhoun, *C. N.* 67, 123; Camerer, *Zeit. Biol.* 29, 239). When this method is applied to urine it must be remembered that uric acid gives off 48 p.c. and creatinin 37 p.c. of its nitrogen in this way (Falck, *Fr.* 21, 300). Nevertheless, the quantity of nitrogen evolved is 8 p.c. less than the calculated amount (R. a. W.). Using Knop's solution, ammonia, urea, and oxamide give off 93, 92·3, and 75 p.c. of their nitrogen as gas (Foster, *C. J.* 35, 470; 35, 119). In the case of urea and oxamide the 'suppressed' nitrogen is present as cyanate and as nitrate (Fauconnier; Luther, *H.* 13, 500). The amount of 'suppressed' nitrogen is less in dilute than in concentrated solutions (Hüfner, *H.* 1, 350; *cf.* Pflüger a. Bohland, *Pf.* 38, 325; 39, 1, 143), and is greatly diminished by the addition of 1 to 5 p.c. acetoacetic ether (Jacoby, *Fr.* 24, 318). According to Duggan (*Am.* 4, 47), if bromine is added to a solution of urea in NaOHAq the yield of nitrogen is 99·4 p.c. of the theoretical amount. In estimating urea in urine Pflüger (*Fr.* 26, 117) adds HClAq (1 c.c.) to urine (10 c.c.), ppts. various nitrogenous bodies by phosphotungstic acid, neutralises the filtrate with lime and then adds an equal volume of conc. NaOHAq and, after allowing to stand for some time, decomposes with Knop's hypobromite. Frothing of albuminous urine can be avoided by first shaking with a pilule of fat (Méhu, *J. Ph.* [5] 15, 607). Hamburger (*R. T. C.* 2, 181) introduced a volumetric method of employing hypobromite, but Pflüger a. Schenck (*Pf.* 37, 399) consider the method to be untrustworthy. E. Salkowski adds two drops of HCl to urine (2·5 c.c.) diluted with 5 or 10 volumes of water until the air is expelled from the flask, then adds the hypobromite, continues boiling, and collects the nitrogen. Fenton (*C. J.* 33, 300) recommends the use of sodium hypochlorite, which was first proposed by E. W. Davy (A.D. 1854). In this case free NaOH must not be present, though excess of Na_2CO_3 may be present.

Mercuric nitrate method. Urea is completely ppd. by a solution of $Hg(NO_3)_2$. The white pp. is not decomposed, and therefore not turned yellow by Na_2CO_3. Urine (2 vols.) is mixed with a solution (1 vol.) prepared from saturated solutions of baryta (2 vols.) and $Ba(NO_3)_2$ (1 vol.); filtered through a dry filter from the ppd. sulphate and phosphate and 15 c.c. (equivalent to 10 c.c. urine) of the filtrate are titrated with standard mercuric nitrate till a drop taken out gives a yellow pp. with Na_2CO_3 (Liebig, *A.* 85, 370). Assuming the compound $CON_2H_4 2HgO$ to be formed, 1 pt. urea should ppt. 7·2 pts. HgO, but in practice 7·72 pts. of the latter are required. A solution of 71·48 g. mercury in HNO_3 diluted to 1 litre is equivalent to ·01 g. urea per c.c. If the urine contains more than 2 p.c. urea the titration gives too low results; in this case the urine must be diluted. When mercuric nitrate is added to a solution of urea nitric acid is set free. Liebig recommended the addition of Na_2CO_3 from time to time to keep the liquid neutral. Pflüger (*Fr.* 19, 375) proceeds as follows: During the titration, after each addition of $Hg(NO_3)_2$ a drop is placed in contact with a little pasty $NaHCO_3$. Long before the titration is ended, a yellow colour is seen between the two drops, but disappears on mixing them together. When the yellow colour is permanent, the titration is near its end; at this point the solution is neutralised by Na_2CO_3, and the titration continued till a permanent yellow colour is got on mixing the drops. Should the entire liquid become yellow on adding Na_2CO_3, a fresh quantity of urea solution must be taken and the operation be repeated with greater speed. The presence of over 1 p.c. NaCl in urine interferes with the titration when Na_2CO_3 is used as indicator, the final reaction not being sharp. Since $NaHCO_3$ does not ppt. $HgCl_2$, when the bicarbonate is used as indicator the titration may proceed as if NaCl were absent, subtracting the amount of $Hg(NO_3)_2$ that is converted into $HgCl_2$ by the chloride (Rautenburg, *A.* 133, 55; Pfeiffer, *Fr.* 24, 475; Pflüger, *Fr.* 27, 120). It is, however, better to ppt. the chlorides by $AgNO_3$ and titrate in the usual way.

Barium carbonate method. The solution is heated with $BaCl_2$ and NH_3Aq in sealed tubes at 220°–240° and the ppd. $BaCO_3$ weighed (Bunsen, *A.* 65, 375). Before applying this method to urine other substances which might form $BaCO_3$ must be ppd. by phosphotungstic acid (Pflüger a. Bleibtreu, *Fr.* 28, 377).

Kjeldahl's method. Nitrogen in urea may be estimated by Kjeldahl's method. 5 c.c. urine are heated with H_2SO_4 (10 c.c.), and Nordhausen H_2SO_4 (10 c.c.) until no more water or gas comes off, and the liquid is clear yellow. After cooling, water (200 c.c.) and NaOH are added and NH_3 distilled off. In the case of urine it must be remembered that about 13 p.c. of the nitrogen is, on an average, combined in substances other than urea (Pflüger, *Pf.* 35, 454; 40, 533; Camerer, *Z. B.* 24, 306).

Other methods. Urea may also be estimated by fermentation and determination of ammonia set free (Miquel, *C. R.* 111, 501).

Campani (*G.* 17, 137) proposes to decompose urea by nitrous acid, and pass the CO_2 into a solution of lime-water of known strength, and titrate with oxalic acid.

Cazeneuve and Hugouneng (*Bl.* [2] 48, 82) heat urea with a large excess of water and titrate the resulting ammonium carbonate.

Riegler (*F.* 33, 49) decomposes urea with Millon's reagent and measures the mixture of N and CO_2 evolved.

Mörner a. Sjöqvist (*Fr.* 30, 388) add 5 c.c. of a saturated solution of $BaCl_2$ containing 5 p.c. baryta to 5 c.c. urine and then add 100 c.c. of a mixture of 97 p.c. alcohol (2 pts.) and ether (1 pt.). After 24 hours the liquid is filtered, the pp. washed with 50 c.c. alcohol-ether, and the filtrate and washings evaporated at 50° to 25 c.c., MgO and some water added, and the evaporation continued as long as NH_3 comes off. The urea is then determined by Bunsen or Kjeldahl's method (Bödtker, *H.* 17, 140).

Salts.—$B'HCl$. Very deliquescent crystalline mass, formed from urea and dry HCl. Decomposed by water into urea and HCl. At 140° it yields NH_4Cl and cyanuric acid.—$B'HNO_3$. Small plates, sl. sol. water and alcohol, v. sl. sol. HNO_3.—$B'_2H_2C_2O_4$. S. 4·4 at 15°. S. (alcohol of S.G. ·833) 1·65. Monoclinic tables; $a:b:c = 1:·564:·491$; $\alpha = 82° 10'$ (Loschmidt, *Sitz. W.* 51, ii. 7, 384). V. sol. hot water. Ppd. from its aqueous solution by oxalic acid.—$B'H_2C_2O_4$aq (Lubavin, *A. Suppl.* 8, 83).—$B'HAuCl_4$aq: orange-red prisms or needles, v. sol. water, alcohol, and ether.—B'_2HAuCl_4: yellow needles, v. sol. hot water (Heintz, *A.* 202, 264).—$B'_2H_2PtCl_6$2aq. Yellow, deliquescent tables, v. sol. water and alcohol, insol. ether (Heintz, *A.* 198, 91).—$B'H_3PO_4$. Large crystals, v. sol. water and alcohol, sl. sol. ether (Lehmann, *Buchn. Rep.* 15, 224; Schmeltzer a. Birnbaum, *Z.* [2] 5, 206). Its solution does not ppt. $MgSO_4$.—$B'_3 2H_3PO_4$. Its aqueous solution gives a crystalline pp. of cyanuric acid on heating.

Tri-chloro-acetate $B'C_2HCl_3O_2$. Plates (from alcohol) (De Clermont, *J.* 1873, 536).—The fumarate $B'_2C_4H_4O_4$, maleates $B'C_4H_4O_4$ and $B'_2C_4H_4O_4$, malate $B'C_4H_6O_5$, gallate $B'C_7H_6O_5$, and succinate $B'_2C_4H_6O_4$ [145°], all crystallise in monoclinic forms (Loschmidt, *Sitz. W.* 52, ii. 238). The parabanate $B'C_3H_2N_2O_3$ and tartrate $B'_2C_4H_6O_6$ are trimetric.—The citrate $B'_2C_6H_8O_7$ is triclinic (L.). An acid tartrate $B'2C_4H_6O_6$ and an acid citrate $B'C_6H_8O_7$ have been prepared (Hlasiwetz, *J.* 1856, 698).—Cyanurate $B'C_3N_3H_3O_3$. Monoclinic crystals.—Picrate $B'C_6H_3N_3O_7$ [142°] (Smolka, *M.* 6, 920). S. 1·9 at 18·5°. S. (95 p.c. alcohol) 3 at 18°. Slender yellow needles (from alcohol). Tri-chloro methane sulphinate $B'CCl_3.SO_2H$. [96°–100°]. Thin prisms (McGowan, *J. pr.* [2] 33, 220).

Compounds with metallic oxides.—$B'_2 3Ag_2O$ (Liebig). Formed by adding moist Ag_2O to a solution of urea. Grey powder composed of slender needles. According to Mulder (*B.* 6, 1019), the yellow pp. got by adding NaOH to a solution of urea mixed with $AgNO_3$ is $CON_2H_2Ag_2$. It combines with iodine, forming $CON_2H_2Ag_2I$, a greenish mass, darkened by light (Tafel a. Enoch, *B.* 23, 1554).—B'_2HgO. Got by adding $Hg(NO_3)_2$ to a solution of urea mixed with KOH. White pp.—$B'_2 3HgO$. White pp. formed by adding $HgCl_2$ to a solution of urea and $HgCl_2$, changes to a yellow granular powder on boiling with water.—$B'HgO$. Formed by adding $Hg(NO_3)_2$ to a warm solution of urea (Dessaignes, *A.* 82, 232; Liebig, *A.* 85, 289).

Compounds with metallic salts.—$B'AgNO_3$. Prisms. Yields silver cyanate on boiling with water.—B'_2PdCl_2. Ppd. by adding a solution of $PdCl_2$ to one of urea (Drechsel, *J. pr.* [2] 20, 469).—$B'NaCl$aq. [60°–70°]. Formed by evaporation of a solution of urea and NaCl. Deliquescent prisms. Alcohol extracts urea from the compound.—$B'NaNO_3$aq. Prisms (from water).—$B'NH_4Cl$. Deliquescent crystals.—$B'_3(NH_4Cl)_2HCl$. Formed by dissolving urea in bleaching-powder solution (Beckmann, *A.* 91, 367). Large plates, sol. alcohol mixed with ether.—$B'_4Mg(NO_3)_2$ (Werther, *J. pr.* 35, 5).—$B'_6Ca(NO_3)_2$.—B'_2ZnCl_2. Very deliquescent crystals (Neubauer a. Kerner, *A.* 101, 337).—$B'CdCl_2$. Needles.—$B'_2Hg(NO_3)_2 3HgO$. Granular powder formed by mixing warm dilute solutions of urea and mercuric nitrate. At the moment of formation the pp. is flocculent.—$B'_2Hg(NO_3)_2 2HgO$. Formed by pouring mercuric nitrate into a solution of urea as long as a pp. is produced, and keeping the whole at 40° to 50° for some time (Liebig). Six-sided laminæ.—$B'_2Hg(NO_3)_2HgO$. Formed by adding an acid solution of mercuric nitrate to a solution of urea nitrate. Crusts of small tabular crystals (Liebig, *A.* 85, 296).—$B'HgCl_2$. Flat crystals, v. sl. sol. cold water (W.).—$B'_{12}Cr_8O_{21}$ 3aq. Formed by the action of water on the product of the action of CrO_2Cl_2 on urea (W. J. Sell, *Pr.* 33, 267; 45, 321). Olive-green needles (from hot water). $PtCl_4$ added to its solution in hot water ppts. silky green needles of $B'_{12}Cr_2Cl_6(PtCl_4)_3$ 2aq. The chromate treated with $PbCl_2$ forms lead chromate and a liquid from which gaseous HCl ppts. green prisms of $B'_{12}Cr_2O_6$ 6aq, the aqueous solution of which heated with Ag_2SO_4 gives dark-green prisms of $B'_{12}Cr_2(SO_4)_3$ 10aq. In a similar way green prisms of $B'_{12}Cr_2(NO_3)_6$ may be got.—$B'_{12}Cr_6Cl_2O_{11}$ 2aq. Green monoclinic crystals, got from the product of the action of CrO_2Cl_2 on urea by crystallising from conc. HClAq (1 vol.) diluted with water (9 vols.). By treatment with water it is split up into $B'_{12}Cr_8O_{21}$ and $B'_{12}Cr_2Cl_6$. By treatment with conc. HClAq (1 vol.) and water (6 vols.) it is converted into the salts $B'_{12}Cr_6Cl_6O_{12}$ 3aq.—$B'_{12}Cr_5O_{12}$ 4aq.—$B'_{12}Cr_2Br_6$ 6aq.—$B'_{12}Cr_2Cl_6$ $6HgCl_2$.—$B'_{12}Cr_4(C_2O_4)_6$ 4aq.—$B'_{12}Cr_2I_{18}$.—$B'_{12}Cr_2(SO_4)_3I_6$.—$B'_{12}Cr_2(CO_3)_2I_4$.—$B'_{12}Cr_2(CO_3)_2I_6$.—$B'_{12}Cr_2Br_{18}$. Bronze-yellow tables, giving off bromine in air.—B'_2CuCl_2. Small blue crystals.

Formyl derivative $NH_2.CO.NH.CHO$. [159°]. H.F. 13,400 (Matignon, *C. R.* 112, 1367). Formed by boiling urea with conc. formic acid (Geuther, *Z.* [2] 4, 300). Crystals, v. sol. water, being decomposed into urea and formic acid.

Acetyl derivative $C_3H_6N_2O_2$ *i.e.* $NH_2.CO.NHAc$. *Acetureide.* Mol. w. 102. [214°]. H.F. −200 (M.). S. (alcohol) 1 in the cold; 10 at 78°. Formed by boiling urea with AcCl or Ac_2O (Zinin, *A.* 92, 405; G.; Zande, *R. T. C.* 8, 235). Got also by the action of $KMnO_4$ on methyl-uracil (Behrend, *A.* 229, 29). Four-sided needles (from alcohol). Slowly but completely decomposed by pure HNO_3 with evolution of CO_2 (1 vol.) and N_2O (2 vols.) (Franchimont, *R. T. C.* 6, 215). It is not ppd. by $Hg(NO_3)_2$.

Di-acetyl derivative $CO(NHAc)_2$. [153°]. A product of the action of $COCl_2$ on acetamide at 50° (Schmidt, *J. pr.* [2] 5, 63).

Formed also from mercuric fulminate and AcCl (Scholl, *B.* 23, 3515). Needles (from alcohol), sl. sol. cold water.

Chloro-acetyl derivative $NH_2.CO.NH.CO.CH_2Cl$. Formed from chloro-acetyl chloride and urea (Jazukovitch, *Z.* 1868, 234; Tommasi, *C. R.* 76, 640). Thin needles (from alcohol). Begins to melt at 160°.

Tri-chloro-acetyl derivative $NH_2.CO.NH.CO.CCl_3$. [150°]. Crystals (from alcohol) (De Clermont, *J.* 1874, 798; Meldola a. Tommasi, *C. J.* 1874, 404; Cloez, *A. Ch.* [6] 9, 219). Nearly insol. hot water.

Bromo-acetyl derivative $NH_2.CO.NH.CO.CH_2Br$. Needles (from dilute alcohol) (Baeyer, *A.* 130, 156). Pure HNO_3 gives off CO_2 (1 vol.) and N_2O (2 vols.) (Franchimont, *R. T. C.* 6, 218).

Tri-bromo-acetyl derivative $NH_2.CO.NH.CO.CBr_3$. [148°]. Formed by the action of Br on an aqueous solution of di-bromo-barbituric acid (Baeyer). Crystals, v. sol. hot alcohol. Yields crystalline $B'_2Ba(OH)_2$ $x$aq, v. e. sol. water.

Cyano-acetyl derivative $NH_2.CO.NH.CO.CH_2Cy$. [200°–210°] (Mulder, *B.* 12, 466). Crystalline.

Butyryl derivative $NH_2.CO.NHC_4H_7O$. [176°]. Formed from urea and butyryl chloride (Moldenhauer, *A.* 94, 101). Plates.

Isovaleryl derivative $C_6H_{12}N_2O_2$. [191°]. Minute prisms, v. sl. sol. water.

Carbonyl derivative $CO(NH.CO.NH_2)_2$. Formed by heating urea with $COCl_2$ at 100° (E. Schmidt, *J. pr.* [2] 5, 39; Emich, *M.* 10, 347). Powder composed of minute crystals, v. sl. sol. cold water and alcohol. Decomposed by heat into NH_3 and cyanuric acid. Boiling KOH also produces cyanuric acid.—$B'HgO$: crystalline powder, insol. water.

Succinyl derivative $C_4H_4O_2(NH.CO.NH_2)_2$. Formed by heating urea (2 mols.) with succinyl chloride (1 mol.) at 65° (Conrad, *J. pr.* [2] 9, 301). Colourless powder, v. sl. sol. hot water.

Methyl-malonyl derivative $CHMe{:}C_2O_2{:}N_2H_2CO$. [192°]. Formed by heating methyl-malonic acid with urea and $POCl_3$ (Franchimont a. Klobbie, *R. T. C.* 7, 22). Pointed plates, v. sol. water and alcohol.

Benzoyl derivative $NH_2.CO.NHBz$. [c. 200°]. S. (alcohol) 1 in the cold; 4 at 78°. Formed by heating urea with BzCl or Bz_2O at 150° (Zinin, *A.* 92, 404; Geuther, *Z.* [2] 4, 299). Four-sided plates (from alcohol), insol. ether).

Di-benzoyl derivative $CO(NHBz)_2$. [210°] (S.); [197°] (H.). A product of the action of $COCl_2$ on benzamide at 165° (E. Schmidt, *J. pr.* [2] 5, 58). Formed also by heating guanidine carbonate with Bz_2O at 100° (Creath, *B.* 7, 1739), and by treating mercuric fulminate with BzCl (Hollemann, *R. T. C.* 10, 72; *B.* 23, 2998, 3742). Needles (from alcohol), sl. sol. water. Aniline at 180° gives NH_3, benzamide, benzanilide, and *s*-di-phenyl-urea.

u-Di-benzoyl derivative $NH_2.CO.NBz_2$. [c. 197°]. Formed by heating sodium benzoyl-cyanamide NaBzN.CN with BzCl, followed by boiling alcohol (Buddéus, *J. pr.* [2] 42, 97). White needles.

m-Nitro-benzoyl derivative $NH_2.CO.NH.CO.C_6H_4.NO_2$ [1:3]. Plates (Griess, *B.* 8, 222).

m-Amido-benzoyl derivative $C_8H_9N_3O_2$. Formed by boiling the preceding body with aqueous ammonium sulphide (G.). Needles (from water), decomposing at 200°. — $B'HCl$ aq: needles.—$B'_2H_2PtCl_6$.

(β)-Naphthoyl derivative $NH_2.CO.NH.CO.C_{10}H_7$. [215°]. Formed from naphthoyl chloride and urea (Vieth, *A.* 180, 319). Minute needles, m. sol. alcohol, v. sl. sol. benzene.

Di-(β)-naphthoyl urea [286°] (Ekstrand, *B.* 20, 1353). Needles.

Lactyl derivative v. Lactyl-urea.

Glycollyl derivative v. Hydantoïn.

Reference.—Oxy-urea.

UREA CARBOXYLIC ACID *v.* Allophanic acid.

UREA CHLORIDES. A name sometimes used to denote alkyl-carbamic chlorides X.NH.CO.Cl.

URECHITIN $C_{28}H_{42}O_8$. Occurs, together with urechitoxin, in the leaves of *Urechites suberecta*, growing in Jamaica (Bowrey, *C. J.* 33, 252). Crystallises from alcohol in needles (containing $x$aq), tastes bitter. It is very poisonous (*Pr.* 27, 309). Nearly insol. water, m. sol. ether. Appears to be a glucoside. Conc. H_2SO_4 forms a yellow liquid, turning red, and finally purple, especially in presence of an oxidising agent.

Urechitoxin $C_{13}H_{20}O_5$. Bitter poison, split up by acids into sugar and urechitoxetin.

UREÏDES. Compounds obtained by elimination of water between urea and an acid or an aldehyde. Many of them may be represented as amides in which NH_2 is replaced by $NH.CO.NH_2$.

BIURET *v.* vol. i. p. 517.

URETHANE *v.* Carbamic ether.

ISURETINE *v.* Formamidoxim.

URIC ACID $C_5H_4N_4O_3$ *i.e.*

$$\mathrm{CO}\left<\begin{array}{l}\mathrm{NH.CO.C.NH}\\ \mathrm{NH{-\!-\!-}C.NH}\end{array}\right>\mathrm{CO}$$

(Medicus, *A.* 175, 243; Fischer, *B.* 17, 329, 1776). Mol. w. 168. S.G. 1·87. H.C.p. 461,400 (Berthelot, *C. R.* 110, 887; Matignon, *C. R.* 110, 1267); 462,500 (Stohmann, *J. pr.* [2] 44, 390). H.C.v. 462,700 (M.). H.F. 148,100 (M.). S. ·002 at 0°; ·006 at 20°; ·0625 at 100° (Blarez a. Denigès, *C. R.* 104, 1847; *cf.* Garrod, *Pr.* 35, 63).

Occurrence.—In urine and in urinary calculi (Scheele, A.D. 1776; Liebig a. Wöhler, *A.* 26, 241; Horbaczewski, *M.* 12, 221). About ·5 g. is daily excreted in human urine. Uric acid occurs in urine of carnivora, herbivora (Mittelbach, *H.* 12, 463), and of birds. Serpent's urine is chiefly composed of acid ammonium urate. A considerable quantity occurs in the blood of gouty subjects, and sodium urate is deposited as 'chalk-stones.' Very small quantities are normally present in the liver, lungs, brain, and blood. It occurs in the green gland of the fresh-water crayfish (Griffiths, *Pr.* 38, 187). Urea, glycocoll, leucine, and aspartic acid given to fowls appear in the urine as uric acid (Jaffé a. Meyer, *B.* 10, 1930; Knierim, *B.* 10, 1930).

Synthesis.—1. By rapidly heating glycocoll (1 pt.) with urea (10 pts.) to 230° (Horbaczewski, *B.* 15, 2678; *M.* 3, 796; 6, 356).—2. By heating urea with tri-chloro-lactic acid or its amide (Horbaczewski, *M.* 8, 201, 584).—3. By preparing methyl-uracil from acetoacetic ether and urea; converting methyl-uracil into nitro-uracil carboxylic acid by treatment with fuming HNO_3; boiling the carboxylic acid with water, and reducing the resulting nitro-uracil to amido-uracil, and finally to isobarbituric acid by means of tin and HClAq; oxidising the isobarbituric acid to isodialuric acid; and heating the isodialuric acid (1 pt.) with urea (1 pt.) and H_2SO_4 (6 pts.) (Behrend a. Roosen, *A.* 251, 235).—4. By fusing urea (4 g.) with cyano-acetic acid (1 g.) (Formánek, *B.* 24, 3419).

Preparation.—1. Serpent's urine is dissolved in boiling KOHAq, filtered, and the uric acid ppd. by HCl or dilute H_2SO_4. If the uric acid is much coloured a little $KMnO_4$ or $K_2Cr_2O_7$ (Gibbs, *Am. S.* [2] 48, 215) should be added to the boiling alkaline solution before ppn.—2. Guano is boiled with borax (1 pt.) and water (120 pts.), and the solution of sodium urate thus obtained ppd. by HCl.—3. Guano is extracted with dilute HClAq, and the residue dissolved in conc. H_2SO_4 and ppd. by water.

Properties.—White anhydrous scales (by ppn.). When slowly deposited from dilute solutions (*e.g.* urine) it separates as large crystals (containing 2aq). Nearly insol. water, insol. alcohol and ether. Sol. conc. H_2SO_4 and reppd. by water. Its solution in hot H_2SO_4 deposits on cooling a deliquescent compound of uric acid with H_2SO_4. Uric acid is m. sol. glycerin, hot NaOAc, and sodium phosphate. Lithium carbonate (1 pt.) dissolved in water (90 pts.) can dissolve uric acid (4 pts.). Aqueous K_2CO_3 also dissolves uric acid.

Reactions.—1. Decomposed by *heat*, without fusion, yielding HCy and a sublimate of cyanuric acid, ammonium cyanate, urea, and ammonium carbonate, and leaving a carbonaceous residue. 2. *Water* at 180° forms mycomelic acid (Hlasiwetz, *A.* 103, 211).—3. *Potash-fusion* yields NH_3 and potassium oxalate, carbonate, and cyanate.—4. *Chlorine* and *bromine* in presence of water yield alloxan, urea, and parabanic acid (Hardy, *A. Ch.* [4] 2, 372). Alloxan is also produced by iodine, by HNO_3, and by MnO_2 and H_2SO_4.—5. Boiling with water and PbO_2 yields allantoïn. Allantoïn is also produced by *ozone* (Gorup-Besanez, *A.* 110, 94), alkaline K_3FeCy_6, $KMnO_4$ (Claus, *B.* 7, 226), and MnO_2 and water. 6. Pure HNO_3 decomposes uric acid in the cold, with evolution of CO_2 (14 vols.), N_2O (24 vols.), and nitrogen (4 vols.) (Franchimont, *R. T. C.* 6, 222). 7. KNO_2 and HOAc yield urinilic acid (Sokoloff, *Z.* [2] 5, 78) and stryphnic acid (Gibbs, *Am. S.* [2] 48, 215).—8. HIAq at 165° forms glycocoll, NH_4I, and CO_2 (Strecker, *Z.* [2] 4, 215).—9. Exposed to the air in alkaline solution it yields oxonic and uroxanic acids.—10. A dilute solution of sodic urate absorbs oxygen from the air at 35° according to the equation $C_5H_4N_4O_3 + O + 2H_2O = C_5H_8N_4O_6$ (uroxanic acid). Uric acid in dilute NaOH solution is completely decomposed by 35 days' digestion at 35° (Nencki a. Sieber, *J. pr.* [2] 26, 18). 5 g. uric acid dissolved in 200 c.c. water and 20 g. potash disappeared in 5 days. However, if no oxygen be present the uric acid is not affected.—11. In fermenting urine uric acid is completely split up into CO_2 and NH_3 (Sestini, *G.* 20, 133).

Detection.—Uric acid may be recognised by its insolubility in water and HClAq, by its crystalline character under the microscope, and especially by the murexide reaction. When evaporated with HNO_3 on a water-bath it leaves an orange residue, which is coloured violet-red by ammonia and violet-blue by potash. A solution of uric acid in aqueous Na_2CO_3 produces a dark-brown spot of reduced silver when added to paper moistened with $AgNO_3$ (Schiff, *A.* 109, 65). Uric acid (1 mol.) reduces boiling Fehling's solution, forming a pp. of Cu_2O (1 mol.) (W. Müller, *J. Th.* 1881, 73). In presence of KOH uric acid dissolves CuO, forming a blue solution, which slowly deposits white cuprous urate. The compound $C_5H_4N_4O_3Cu_2O$ is ppd. when an alkaline solution of uric acid is treated with Fehling's solution and hydroxylamine hydrochloride (Balke, *J. pr.* [2] 47, 546). Uric acid evaporated with a little dilute HNO_3 gives a blue colour on shaking with H_2SO_4 and benzene containing thiophene (Denigès, *J. Ph.* [5] 18, 161).

Estimation in urine.—1. Urine (500 c.c.) is concentrated, HCl is added, and after twenty-four hours the pp. is collected and weighed. Uric acid may be separated from xanthine by ppn. with conc. H_2SO_4 (Horbaczewski, *H.* 18, 341; *cf.* Wulff, *H.* 17, 634).—2. Urine (200 c.c.) is mixed with conc. Na_2CO_3Aq (10 c.c.), and after an hour conc. NH_4ClAq (20 c.c.) added. After forty-eight hours the pp. is collected, washed with HCl (1 pt. of S.G. 1·123), diluted with water (10 pts.), the washings allowed six hours to deposit any dissolved uric acid, the combined pps. washed with alcohol and dried at 110° (Salkowski, *Fr.* 16, 373). Uric acid may also be ppd. as ammonium urate by saturating urine with solid NH_4Cl (30 g. to 100 c.c.) (Hopkins, *Pr.* 52, 93).—3. Fresh urine is mixed with very dilute (·15 p.c.) NaOHAq, filtered from phosphates, and diluted to S.G. 1·010. To 300 c.c. of this solution is added 50 c.c. of magnesia mixture [$MgSO_4$ 7aq (1 pt.), NH_4Cl (2 pts.), NH_3Aq (4 pts. of S.G. ·924), and water (8 pts.)]. The pp. is filtered off, and 175 c.c. of the filtrate mixed with ·5 g. $CaCO_3$ and 5 c.c. of a 3 p.c. solution of $AgNO_3$. The pp. is washed and dried, and a nitrogen estimation made by Kjeldahl's method (Camerer, *Z. B.* 26, 84; *cf.* Salkowski, *Pf.* 5, 319).—4. Urine (25 c.c.) is mixed with $NaHCO_3$ (1 g.), and NH_3Aq (2 to 3 c.c.), and ammoniacal $AgNO_3$ (1 to 2 c.c. of a solution of 5 g. $AgNO_3$ in 100 c.c. water, to which NH_3Aq is added till the ppd. Ag_2O is just re-dissolved). The pp. is collected, washed, dissolved in HNO_3, and the silver determined volumetrically by the sulphocyanide method (Haycraft, *Fr.* 25, 167; 30, 648). This method is liable, according to Salkowski (*H.* 14, 31) and Gossage (*Pr.* 44, 384), to an error which may amount to 60 p.c. The error is partly due to variations in composition of the silver urate, and partly to presence of bodies of the xanthine group (Deroide, *Bl.* [3] 7, 363). *V.* also Herrmann, *H.* 12, 496; Czapek, *H.* 12, 502).—5. In a solution containing not more than ·0125 p.c. of uric acid 1 c.c. of decinorma permanganate is reduced by ·0074 g. uric acid (Blarez a. Denigès, *C. R.* 104, 789).—6. By treat ment with a standard iodine solution in presence of alkali (Kreidl, *M.* 14, 109).

Salts.—$(NH_4)HA''$. S. ·06 at 15°. Slender needles.—$(NH_4)_3HA''_2$.—$(NH_4)_4H_2A''_3$ (Maly, *J.* 1863, 621).—K_2A''. S. 3 at 16°. Small needles.—KHA''. S. ·13 at 20°. Amorphous.—Na_2A'' aq. S. 1·5. Nodules.—$NaHA''$ ½aq (dried at 100°). Crystalline powder. S. ·09 at 15°; ·8 at 100°. Occurs as an amorphous urinary deposit.—$LiHA''$. S. ·27 at 20; ·9 at 40°; 2·5 at 100° (Schilling, *A.* 122, 241).—BaA''aq (dried at 100°). Granular pp. S. ·013 in the cold.—$BaH_2A''_2$ 2aq (dried at 100°). Amorphous, insoluble powder (Behrend a. Roosen, *A.* 251, 250).—CaA''. S. ·066 in the cold; ·07 at 100°.—$CaH_2A''_2$ 2aq. S. ·15 in the cold; ·37 at 100°. More sol. KClAq.—SrA'' 2aq. Minute stellate groups of needles. S. ·023 in the cold; ·055 at 100°.—$SrH_2A''_2$ 2aq.—$MgH_2A''_2$ 6aq. S. ·03 in the cold; ·6 at 100°.—$PbH_2A''_2$ (dried at 100°). Insol. water.—PbA'' (dried at 100°).—Cu_2A'' aq.—$Cu_3A''_2(OH)_2$ 4aq: green pp.

Reference.—METHYL-URIC ACID.

Iso-uric acid $C_5H_4N_4O_3$. Formed by boiling cyanamide (1 pt.) with an aqueous solution of alloxantin (2 pts.) (Mulder, *B.* 6, 1236; 7, 1633). Powder, almost insol. water. Oxidised by boiling with I and water. Its solution in K_2CO_3 reduces $AgNO_3$.

Pseudo-uric acid $C_5H_6N_4O_4$ *i.e.*

$$CO\!\left\langle\begin{matrix}NH.CO\\NH.CO\end{matrix}\right\rangle\!CH.NH.CO.NH_2$$

Formed by the action of KCyO on uramil (Baeyer, *A.* 127, 3), and by heating uramil with urea at 180° (Grimaux, *Bl.* [2] 31, 535). White crystalline powder composed of small prisms, v. sl. sol. water. HNO_3 yields alloxan. Boiled with water and PbO_2 it yields oxalic acid, but no allantoïn. H_2SO_4 at 150° forms xanthinine.—$(NH_4)HA''$ aq.—KHA''aq: scales.—$NaHA''$ 2aq: groups of prisms, v. sol. hot water.—BaA'' 5aq: groups of slender needles.

URINILIC ACID $C_8H_7N_7O_6$. Formed by the action of KNO_2 and HOAc on uric acid (Sokoloff, *Z.* 1869, 78). Prisms (from water).—K_2HA'''. Prisms, v. e. sol. water. $Ca_3A'''_2$. Crystalline pp. insol. water and HOAc.—$Sr_3A'''_2$.—$Ba_3A'''_2$.—$CdHA'''$ 3aq.—$CuHA'''$ 4aq. Slender red needles.—Ag_2HA'''. Pp.—Ag_3A'''. Gelatinous pp. quickly blackening in light.

UROBILIN.

Occurrence.—Often in urine (Jaffé; Disqué, *H.* 2, 271; *C. C.* 1878, 711; Eikholz, *J. Physiol.* 14, 326). In bile, especially of the mouse.

Preparation.—Urine containing urobilin is ppd. by lead acetate and sub-acetate until the absorption band at F is removed. The pp. is extracted with alcohol, acidified with HCl or H_2SO_4, filtered, diluted with water, and extracted with chloroform.

Properties.—A red amorphous, shiny substance. Prepared as above it contains HCl or H_2SO_4, as the case may be. Its spectrum exhibits a dark band at F, destroyed by NH_3, but on adding NaOH another band near the red is formed (MacMunn, *Pr.* 30, 250; 31, 26, 206; *v.* also HYDROBILIRUBIN, this vol. p. 273.

Detection and estimation in urine: Jolles, *H.* 18, 545; Studensky, *C. C.* 1893, ii. 668.

UROCANINIC ACID $C_{12}H_{12}N_4O_4$. [213°]. Occurs in dog's urine (Jaffé, *B.* 7, 1669; 8, 811). Prisms (containing 4aq), v. sol. hot water, insol. alcohol and ether. Decomposed by fusion into CO_2 and **urocanine** $C_{11}H_{10}N_4O$, an amorphous base yielding $B'H_2PtCl_6$.—$HA'2HCl$: needles, v. e. sol. water.—$HA'2HNO_3$: crystalline pp. insol. dilute HNO_3, v. sol. water.—$HA'H_2SO_4$. Minute needles and plates.

UROCHLORALIC ACID $C_8H_{11}Cl_3O_7$ (?) [142°]. S. (ether) ·4. Found in the urine after administration of chloral (Von Mering a. Musculus, *B.* 8, 662; *H.* 6, 483; Külz, *C. C.* 1881, 486). Silky needles, v. e. sol. water and alcohol. Decomposed by boiling dilute H_2SO_4 into tri-chloro-ethyl alcohol and glycuronic acid $C_6H_{10}O_7$.—NaA'.—KA'.—BaA'_2: satiny plates (from ether-alcohol).

UROFUSCOHÆMATIN *v.* this vol. p. 274.

UROLEUCIC ACID $C_9H_{10}O_5$. [133·5°]. An acid occurring in human urine which darkens on addition of alkalis (Kirk, *Brit. Med. Journ.* [1888] 2, 232). Crystals. Its solution is ppd. by $Pb(OAc)_2$ and gives a transient green colour with very dilute $FeCl_3$. $FeCl_3$ colours the crystals red.

UROMELANIN $C_{18}H_{43}N_7O_{10}$. A black substance which separates on treating urine with H_2SO_4 or HClAq in presence in air (Thudichum, *J. pr.* 104, 257; *C. R.* 106, 1803; Plosz, *H.* 8, 89; Udranski, *H.* 11, 537; 12, 32; this vol. p. 274). It yields $C_{18}H_{40}AgN_7O_8$ (Thudichum).

URONITROTOLUOLIC ACID $C_{13}H_{15}NO_9$. Occurs in urine of dogs after a dose of *o*-nitro-toluene (Jaffé, *H.* 2, 47). Very deliquescent. Asbestos-like mass, v. e. sol. water and alcohol. Decomposed by dilute H_2SO_4 into *o*-nitro-benzyl alcohol and a syrupy acid. **Salts.** — BaA'_2: crystalline powder, v. e. sol. water, insol. alcohol.—$CO(NH_2)_2HA'$ 2½aq. [149°]. Needles, v. e. sol. water, sl. sol. cold alcohol.

UROROSEÏN *v.* this vol. p. 274.

UROSULPHINIC ACID $C_5H_4N_4SO_2$. Formed by heating thio-uramido-barbituric acid (1 pt.) with H_2SO_4 (2 pts.) at 160° (Nencki, *B.* 4, 724; 5, 45). Nodules (from hot HClAq). Its K salt crystallises in needles, m. sol. cold water.

UROXANIC ACID $C_5H_8N_4O_6$. Formed by leaving a solution of uric acid (5 g.) in water (200 c.c.) containing KOH (20 g.) to stand for 5 days at 35°, neutralising by HOAc, filtering, and evaporating (Nencki a. Sieber, *J. pr.* [2] 24, 504; *cf.* Städeler, *A.* 78, 286; 80, 119; Strecker, *A.* 155, 177; Mulder, *B.* 8, 1291). Tetrahedra, sl. sol. cold water, insol. alcohol. Decomposed by boiling water into CO_2, urea, and allanturic acid.—K_2A''3aq. Four-sided pearly plates, v. sol. hot water.—CaA'' 4aq.—BaA'' 5aq.—PbA'' ½aq. Insol. water.—Ag_2A'': flocculent pp., turned red by light.

URSONE $C_{30}H_{48}O_3$ 2aq. [265°] (Gintl, *M.* 14, 255). Occurs in the leaves of the red bear-berry (*Arctostaphylos Uva-ursi*) (Trommsdorff, *Ar. Ph.* [2] 80, 273; Hlasiwetz, *J. pr.* 66, 123). Needles, insol. water, acids, and alkalis, sl. sol. alcohol and ether. Conc. H_2SO_4 added to its solution in Ac_2O gives a red colour, changing through blue to green. Does not react with hydroxylamine or phenyl-hydrazine. Reduced by HI and P at 360° to $C_{15}H_{24}$ (256°–267°).

Acetyl derivative [264°].

Benzoyl derivative [214°].

URUSHIC ACID $C_{14}H_{18}O_2$. S.G. ^{25} ·985. Occurs in urushi or Japanese lacquer (Yoshida, *C. J.* 43, 472). Dark, pasty mass, v. sol. benzene and ether, insol. water. Br in CS_2 forms $C_{14}H_{12}Br_6O_2$. HNO_3 forms $C_{14}H_{16}(NO_2)_2O_2$, which forms FeA'_3. Chromic acid mixture forms oxy-urushic acid $C_{14}H_{18}O_3$.—PbA'_2 (dried at 100°). [110°-115°]. Flocculent pp.—$FeH_9A'_{12}$ 2aq.—$FeH_3A'_6$. Deep-black pp.

USNETIC ACID $C_9H_{10}O_3$. [178°]. Occurs in small quantity, together with usnic acid, in the lichen *Usnea barbata* (Hesse, *B.* 10, 1326). Flat prisms (from alcohol), v. sol. ether. $FeCl_3$ colours its alcoholic solution bluish-violet. Bleaching-powder does not colour its alkaline solution. Is perhaps identical with decarbusnin.

USNIC ACID $C_{18}H_{16}O_7$ (Salkowski; Paterno) or $C_{19}H_{16}O_8$ (Hesse), or $C_{18}H_{18}O_7$ (Stenhouse a. Groves, *C. J.* 39, 234). *Carbusnic acid.* [195·4° cor.]. S. (ether) ·3 at 20°. Occurs in the lichens *Usnea barbata*, *Usnea florida*, *Zeora sordida* (Knop, *A.* 49, 103; Rochleder a. Heldt, *A.* 48, 12; Thomson, *A.* 53, 252; Stenhouse, *Pr.* 18, 222; *A.* 68, 97, 114; 155, 51; Hesse, *A.* 117, 343; Paterno, *G.* 8, 225; Salkowski, *B.* 8, 1459). Sulphur-yellow monoclinic crystals, sl. sol. alcohol, v. sol. hot ether and benzene. Does not yield betorcin when heated. Conc. H_2SO_4 forms **usnolic acid** $C_{27}H_{24}O_{10}$ [213°] crystallising in small yellowish prisms (Stenhouse a. Groves, *C. J.* 39, 236). When it is heated with an alcoholic solution of aniline it yields the anilide $C_{18}H_{15}O_6(NHPh)$, crystallising from alcohol in pale-yellow plates [171°], and forming in KOHAq a yellow solution from which HCl ppts. $C_{23}H_{23}NO_6$ [171°].

Salts.—$NaC_{18}H_{17}O_8$ 2aq (Spica, *G.* 12, 432). Pale-yellow, silky needles.—$KC_{19}H_{15}O_8$ 3aq or $KC_{18}H_{17}O_8$ 3aq. Pale-yellow plates (from 50 p.c. alcohol) (Hesse, *B.* 10, 1325).—$KC_{19}H_{15}O_8$ aq or $KC_{18}H_{17}O_8$ aq. Yellow prisms (from 93 p.c. alcohol).—CuA'_2: green pp.

Decarbusneïn $C_{17}H_{18}O_6$. [175°]. Formed by heating usnic acid (1 pt.) with alcohol (3⅓ pts.) at 150° (Paterno, *G.* 12, 234). Yellow, silky needles, sol. hot alcohol, sl. sol. water and ether. Not coloured by $FeCl_3$. Not attacked by AcCl. Reduces warm ammoniacal $AgNO_3$. Boiling KOHAq in absence of air splits it up into HOAc and **decarbusnic acid** $C_{15}H_{16}O_5$, which crystallises from alcohol in lemon-yellow prisms [199°] and yields, when boiled with Ac_2O, two acetyl derivatives $C_{15}H_{15}AcO_5$ [148°] (isomeric with decarbusneïn) and $C_{15}H_{14}Ac_2O_5$ [131°].

Pyrousnic acid $C_{12}H_{12}O_5$ (P.); $C_9H_8O_4$ (Salkowski, *B.* 8, 1461). [197°]. Formed, together with pyrousnetic acid, by boiling usnic acid (2 pts.) with KOH (5 pts.) and water (5 pts.) in an atmosphere of hydrogen (Paterno, *G.* 13, 313; 12, 242). Shining scales (from ether), v. sol. alcohol, sl. sol. ether. Its alkaline solution absorbs oxygen from the air, turning green and ultimately brown. Reduces ammoniacal $AgNO_3$ readily. Ac_2O yields an acetyl derivative [205°]. Alcohol and HCl form an ether [147°]. Pyrousnic acid is split up on dry distillation in a current of H into CO_2 and **usneole** $C_{11}H_{12}O_3$, which crystallises from alcohol in yellow prismatic tablets [176°] and is converted by AcCl into a di-acetyl derivative [142°].

Pyrousnetic acid $C_{14}H_{14}O_6$ *i.e.* $C_{13}H_{13}O_4(CO_2H)$. [186°]. Formed by boiling usnic acid (10 pts.) with KOH (25 pts.) and water (25 pts.) for 15 minutes (Paterno, *G.* 12, 238). Colourless plates or needles (from alcohol). Ac_2O yields $C_{14}H_{13}AcO_6$ [168°]. When heated in a current of H, pyrousnetic acid is split up into CO_2 and **usnetole** $C_{13}H_{14}O_4$, which crystallises from dilute alcohol in yellowish needles [179°].

(β)-Usnic acid *v.* CLADONIC ACID.

UVIC ACID *v.* PYROTRITARIC ACID.

UVINONE $C_{14}H_{12}O_4$ *i.e.*

$O\left<\begin{matrix}CMe:C.CO.C:CMe\\CMe:C.CO.C:CMe\end{matrix}\right>O$ (?) [247°]. Formed, to the extent of 2 p.c., by distilling pyrotritaric acid (Dietrich a. Paal, *B.* 20, 1086). Yellow needles (by sublimation), sol. HOAc, v. sl. sol. alcohol. Conc. H_2SO_4 forms a solution with green fluorescence. Br at 100° forms crystalline $C_{12}H_4Br_8O_4$.

UVITIC AICD $C_9H_8O_4$ *i.e.* $C_6H_3Me(CO_2H)_2$ [1:3:5]. *Mesidic acid.* Mol. w. 180. [288°]. H.C.v. and p. 928,900. H.F. 193,100 (Stohmann, *J. pr.* [2] 40, 128). Formed, together with uvitonic acid, by boiling pyruvic acid with baryta-water (Finck, *A.* 122, 184). Formed also by oxidation of mesitylene or mesitylenic acid (Fittig a. Von Furtenbach, *Z.* [2] 4, 1; *A.* 147, 295), by oxidation of di-methyl-ethyl-benzene (Wroblewsky, *A.* 192, 217), and by heating $C_6H_2Me(SO_2NH_2)(CO_2H)_2$ with conc. HClAq at 230° (Hall a. Remsen, *Am.* 2, 136). Slender needles (from water), v. sl. sol. hot water, m. sol. alcohol and ether. Yields toluene on heating with soda-lime (Baeyer, *Z.* [2] 4, 119). The Ca salt heated with lime yields *m*-toluic acid (Böttinger a. Ramsay, *A.* 168, 255). Chromic acid mixture oxidises it to trimesic acid.

Salts.—K_2A'': plates (from alcohol), v. sol. water.—BaA″ aq.—CaA″ aq.—Ag_2A''. Nearly insol. cold water.

Ethyl ether Et_2A''. [35°]. Crystalline.

References.—AMIDO-, BROMO-, NITRO-, and OXY-UVITIC ACID.

Isouvitic acid *v.* CARBOXY-PHENYL-ACETIC ACID.

Uvitonic acid *v.* METHYL-PYRIDINE-DICARBOXYLIC ACID.

VALERAL *v.* VALERIC ALDEHYDE.

VALERAL-DI-ACETONAMINE *v.* *Pentylidene di*-ACETONAMINE.

VALERALDINE $C_{15}H_{31}NS_2$. *Thiovaleraldine.* [41°]. Formed by the action of H_2S on isovaleric aldehyde ammonia suspended in water (Beissenhirtz, *A.* 90, 109; Parkinson, *A.* 90, 119). Formed also from thio-isovaleric aldehyde and dry NH_3 (Schröder, *B.* 4, 468). Plates (from ether), with powerful smell, sol. alcohol, insol. water.—B'HCl. Needles, sol. water.

VALERCREATININ *v.* METHYL-GUANIDO-VALERIC ACID.

VALERIAN OIL. An essential oil obtained from the root of *Valeriana officinalis*. It contains a terpene $C_{10}H_{16}$ (156°) $[\alpha]_D = -21°$, a camphene, borneol $C_{10}H_{18}O$, di-bornyl oxide $(C_{10}H_{17})_2O$ (285°–290°), formyl-, acetyl-, and valeryl-borneol, and a little valeric acid (Gerhardt, *A. Ch.* [3] 7, 275; Pierlot, *A. Ch.* [3] 56, 291; Bruylants, *J. Ph.* [4] 27, 349; *B.* 11, 452; Haller, *C. R.* 103, 151; Oliviero, *C. R.* 117, 1096).

***n*-VALERIC ACID** $C_5H_{10}O_2$ *i.e.* $CH_3.CH_2.CH_2.CH_2.CO_2H$. Mol. w. 102. (186° cor.). S.G. $\frac{0}{0}$ ·9562 (Zander, *A.* 224, 65); $\frac{15}{15}$ ·9446; $\frac{25}{25}$ ·9375 (Perkin); $\frac{20}{4}$ ·9298 (Brühl). C.E. (0°–10°) ·00098 (Z.). S. 3·5 at 16°. S.V. 130·0 (Z.). M.M. 5·513 at 13·6°. $\mu_\beta = 1·4093$. $R_\infty = 43·16$ (Brühl). H.F. 137,800 (Stohmann, *J. pr.* [2] 49, 99). Occurs in crude wood vinegar (Grodzki a. Krämer, *B.* 11, 1358).

Formation.—1. By saponifying its nitrile (*n*-butyl cyanide) (Lieben a. Rossi, *A.* 159, 58; *G.* 1, 239).—2. By oxidation of *n*-amyl alcohol (L. a. R.).—3. By the action of metallic silver on a mixture of EtI and *β*-iodopropionic acid (W. von Schneider, *Z.* [2] 5, 343).—4. By oxidising *a*-oxy-*n*-caproic acid (Erlenmeyer, *B.* 9, 1840).—5. By heating *β*-acetyl-propionic acid with HI and P at 200° (Kehrer a. Tollens, *A.* 206, 233).—6. By reducing *β*-acetyl-propionic acid with sodium-amalgam (Wolff, *A.* 208, 110).—7. By heating *n*-propyl-malonic acid at 180° (Juslin, *B.* 17, 2504; Furth, *M.* 9, 308).—8. By fermentation of calcium lactate (Fitz, *B.* 13, 1309; 14, 1084). 9. By heating the lactone of *γ*-oxy-*n*-valeric acid with HIAq and P at 240° (Fittig, *A.* 226, 346).—10. A product of oxidation of castor oil by dilute HNO_3 (Wahlforss, *B.* 22 Ref., 438).

Properties.—Liquid, smelling like butyric acid.

Salts.—KA'. Plates (from alcohol).—CaA'_2aq. S. 10·267 at 0°; 8·144 at 60°. Least soluble at 60°–70° (F.);—$CaA'_2 1\frac{1}{2}$aq (Schorlemmer, *A.* 161, 270).—BaA'_2. S. 21·693 at 0°; 23·076 at 80°.—MnA'_2aq.—CuA'_2: minute green needles. More sol. cold than hot water.—ZnA'_2. S. 2·6 at 25°.—AgA'. S. ·229 at ·3°; ·641 at 70·5°.

Methyl ether MeA'. (127·3°). S.G. $\frac{0}{0}$ ·9097 (G.); $\frac{20}{4}$ ·8795. C.E. (0°–10°) ·00106. S.V. 149·1 (Gartenmeister, *A.* 233, 273). $\mu_\beta = 1·3997$. $R_\infty = 50·7$.

Ethyl ether EtA'. Mol. w. 130. (144·7° cor.). S.G. $\frac{0}{0}$ ·8939 (G.); $\frac{20}{0}$ ·8765 (Lieben a. Rossi, *A.* 165, 117); $\frac{20}{4}$ ·8661 (Brühl). S.V. 174·3. C.E. (0°–10°) ·00111. $\mu_\beta = 1·402$. R_∞ 58·03 (B.).

n-Propyl ether PrA'. (167·5°). S.G. $\frac{0}{0}$ ·8888. C.E. (0°–10°) ·00106 (G.). S.V. 197·8.

n-Butyl ether C_4H_9A'. (185·8°). S.G. $\frac{0}{0}$ ·8847. C.E. (0°–10°) ·00101. S.V. 222·1.

n-Amyl ether $C_5H_{11}A'$. Mol. w. 172. (203·7°). S.G. $\frac{0}{0}$ ·8812 (G.); $\frac{20}{4}$ ·8568 (Brühl). C.E. (0°–10°) ·00097. S.V. 245·8. μ_β 1·417. R_∞ 80·48.

n-Hexyl ether $C_6H_{13}A'$. (223·8°). S.G. $\frac{0}{0}$ ·8797. C.E. (0°–10°) ·00096. S.V. 272·0.

n-Heptyl ether $C_7H_{15}A'$. (243·6°). S.G. $\frac{0}{0}$ ·8786. C.E. (0°–10°) ·00090. S.V. 297·4.

n-Octyl ether $C_8H_{17}A'$. (260·2°). S.G. $\frac{0}{0}$ ·8784. C.E. (0°–10°) ·00088. S.V. 322·6.

Amide $C_4H_9.CO.NH_2$. Mol. w. 101. [116°]. Pearly plates (Weidel a. Ciamician, *B.* 13, 69). V. sol. water, alcohol, and ether.

Nitrile $C_4H_9.CN$. *n-Butyl cyanide.* (140°). S.G. ^{0} ·816 (Lieben a. Rossi, *A.* 158, 171). Formed, together with amylamine, by allowing a mixture of hexoic amide (1 mol.) and bromine (2 mols.) to run into a 10 p.c. solution of NaOH (Hofmann, *B.* 17, 1410).

Isovaleric acid $(CH_3)_2CH.CH_2.CO_2H$. *Isopropyl-acetic acid.* (176° cor.). S.G. $\frac{15}{15}$ ·9336; $\frac{25}{25}$ ·9261 (Perkin); $\frac{20}{20}$ ·931 (E. a. H.). M.M. 5·635 at 16°. S. 4·24 at 20°.

Vapour tension: Richardson, *C. J.* 49, 767.

Heat of neutralisation: Gal a. Werner, *Bl.* [2] 46, 801.

Occurs in the fat of *Delphinum Phocæna* (Chevreul [1817], *Corps gras*, pp. 99, 209), in valerian root (Grote, *B. J.* 11, 225; Trommsdorff a. Ettling, *A.* 4, 229; 6, 176), in the root of *Angelica Archangelica* (Meyer a. Zenner, *A.* 55, 328), in the root of *Athamanta Oreoselinum*, in the bark of the alder tree, in the berries and bark of the Guelder rose (*Viburnum Opulus*) (Moro, *A.* 55, 330), in the root of *Viburnum prunifolium* (Allen, *Ph.* [3] 11, 413), and in oil of geranium (O. Jacobsen, *A.* 157, 232). A valeric acid occurs in rosin oil (Lwoff, *B.* 20, 1017) and in yolk of wool (suint) (Buisine, *Bl.* [2] 48, 639).

Formation.—1. By oxidation of inactive fermentation amyl alcohol (Dumas a. Stas, *A.* 33, 156; 35, 143; Erlenmeyer a. Hell, *A.* 160, 257; Pedler, *C. J.* 21, 74).—2. By boiling its nitrile with alcoholic potash (E. a. H.; Schmidt a. Sachtleben, *A.* 193, 87).—3. Together with the active acid by oxidation of leucine (amido-hexoic acid) (E. a. H., *cf.* Neubauer, *A.* 106, 59).—4. By heating isopropyl-malonic acid at 180° (*B.* 11, 596).—5. By oxidising di-methyl-allyl-carbinol, treating the resulting $CMe_2(OH).CH_2.CO_2H$ with HI, and reducing the *β*-iodo-valeric acid so formed by means of 3 p.c. sodium-amalgam applied in an acid solution (Schirokoff, *J. pr.* [2] 23, 286).—6. By the action of KOH or HClAq on *Athamantin* (Schnedermann a. Winckler, *A.* 51, 324).—7. By putrefactive fermentation of proteïds (Iljenko, *A.* 63, 269).—8. By the action of CrO_3 on gelatin and albumen (Schlieper, *A.* 59, 7; Guckelberger, *A.* 64, 71).—9. From isopropyl-aceto-acetic ether (Frankland a. Duppa, *A.* 145, 84).—10. By distilling isopropyl-malonic acid (Conrad a. Bischoff, *A.* 204, 151).—11. A product of distillation of colophony (Renard, *A. Ch.* [6] 1, 253).

Preparation.—1. *Isoamyl alcohol* is oxidised by less than the calculated quantity of $KMnO_4$ in the cold. Some acetic acid is formed, but this can be got rid of by distilling a dilute solution of the acids, for valeric acid passes over in the first quarter of the distillate, the acetic acid remaining behind (Duclaux, *C. R.* 105, 171).—2. By oxidising isoamyl alcohol (1,000 c.c.) with $K_2Cr_2O_7$ (1000 g.) dissolved in water (3,500 c.c.) by adding in the cold H_2SO_4 (1,400 g.) mixed with water (800 g.). The resulting isoamyl isovalerate is saponified by potash (Pierre a. Puchot, *A. Ch.* [4] 29, 229).—3. By distilling valerian root with dilute phosphoric acid, neutralising the distillate with Na_2CO_3, and decomposing the resulting Na salt by H_2SO_4. In purifying valeric acid use may be made of the fact that the acid forms crystalline acid salts with K and Na (Lescœur, *Bl.* [2] 27, 104).

Properties.—Liquid, inactive to light. Its smell is powerful and unpleasant. Sl. sol. water. Separated from aqueous solution by $CaCl_2$. Volatile with steam. Mixes with alcohol and ether. It is set free from its salts by mineral acids, by HOAc, by oxalic, tartaric, citric, and malic acids, but not by butyric acid. When conc. valeric acid is added to a solution of cupric acetate, anhydrous cupric valerate separates in oily drops, which soon change to a greenish-blue crystalline powder of the hydrated salt; butyric acid would at once give a crystalline pp. (Larocque a. Huraut, *J. Ph.* [3] 9, 430).

Reactions.—1. *Oxidised* by chromic acid mixture at 20° to acetic acid and CO_2.—2. Boiling dilute HNO_3 forms nitro-valeric acid, methyl-malic acid, and a little di-nitro-propane (when prepared from valerian) or di-nitro-butane (when prepared from isoamyl alcohol) (Bredt, *B.* 14, 1782; 15, 2319; *cf.* Dessaignes, *A.* 79, 374).—3. Dilute alkaline $KMnO_4$ forms $CMe_2(OH).CH_2.CO_2H$.—4. Electrolysis of the K salt in conc. solution yields octane $C_2H_4Pr_2$ (Kolbe, *A.* 69, 259).—5. Passed through a *red-hot tube* it yields ethylene, propylene, butylene, and other hydrocarbons (Hofmann, *C. J.* 3, 121).—6. The Ca salt yields di-isobutyl ketone on distillation by itself, valeric aldehyde on distillation with calcium formate, and methyl isobutyl ketone on distillation with calcium acetate.

Salts.—NH_4A'. V. sol. water and alcohol.—$(NH_4)H_2A'_3$.—KA'. Deliquescent crystalline mass. S. (alcohol) 26 at 20°. [140°].—LiA'$\frac{1}{2}$aq. Nodules.—TlA'. V. sol. water.—$CaA'_2$3aq: needles (Barone, *A.* 165, 120; Schmidt a. Sachtleben, *A.* 193, 87; Schirokoff, *J. pr.* [2] 23, 286). S. 18·4 at 0° (Sedlitzky, *M.* 8, 563).—$CaA'_2$4aq.—$CaA'_2$5aq.—BaA'_2. Triclinic plates. S. 94 at 18°. S. (alcohol) 3·3 at 20°.—BaA'_2aq.—$BaA'_2$2aq.—SrA'_2.—$MnA'_2$2aq.—$ZnA'_2$2aq. Crystalline.—ZnA'_2. S. 1 in the cold. S. (80 p.c. alcohol) 1·7 in the cold; S. (ether) ·2 in the cold; ·5 at 35° (Wittstein, *J.* 1847, 557).—$ZnA'_2$12aq.—$ZnA'_2$3aq.—$ZnA'_2 2NH_3$ (Lutschak, *B.* 5, 30).—CuA'_2. Green crystalline pp.—CuA'_2aq.—$Bi_6A'_4(OH)_8O_3$ (Schucht, *Ar. Ph.* [3] 2, 97).—FeA'_3.—$FeA'_2(OH)$.—$Fe_2A'_4(OH)_2$.—PbA'_2: easily fusible laminæ.—$Pb_3A'_2O_2$. Groups of needles, sl. sol. water.—AgA'. S. ·177 at 0° (Sedlitzky); ·185 at 20° (Erlenmeyer).

Methyl ether MeA'. (116°). S.G. $\frac{0}{4}$ ·9007. C.E. (0°–10°) ·001174. S.V. 149·6 (Elsässer, *A.* 218, 315); 148·3 (R. Schiff, *A.* 220, 334). S.H. (21°–45°) ·491 (Kopp). Smells like bananas.

Ethyl ether EtA'. (134°). (E.); (135° cor.) (Perkin). S.G. $\frac{0}{4}$ ·8851 (E.); $\frac{15}{15}$ ·8714; $\frac{25}{25}$ ·8632 (P.). C.E. (0°–10°) ·001034. S.V. 173·4 (E.); 173·0 (S.). M.M. 7·615 at 18°. Oil, sol. alcohol. Smells like rennet apples and water-mint (Pierre a. Puchot, *A. Ch.* [4] 29, 234). Converted by sodium into oxy-decoic acid, ethyl ethoxy-decoate (Hantzsch, *A.* 249, 64), an acid $C_{20}H_{34}O_3$ [c. 127°] (295°), and other bodies (Greiner, *Z.* [2] 2, 460; Wanklyn, *C. J.* 17, 371; Geuther a. Greiner, *J.* 1865, 319).

n-Propyl ether PrA'. (156°). S.G. $\frac{0}{4}$ ·8809. C.E. (0°–10°) ·000997. S.V. 197·5 (Elsässer); 196·8 (Schiff).

Isopropyl ether PrA'. (142°). S.G. ^{0} ·870; ^{17} ·854 (Silva, *A.* 153, 136).

Di-chloro-propyl ether $C_3H_5Cl_2A'$. (245°) at 737 mm. S.G. ^{11} 1·149. Formed from epichlorhydrin and isovaleryl chloride (Truchot, *A.* 138, 298).

Isobutyl ether C_4H_9A'. (169°) (Elsässer, *A.* 218, 328); (173°) (P. a. P.). S.G. $\frac{0}{4}$ ·8736 (E.). ^{0} ·8884 (P. a. P.). C.E. (0°–10°) ·001027. S.V. 223·4 (E.).

Isoamyl ether $C_5H_{11}A'$. (188°) (Kopp; R. Schiff, *A.* 234, 344); (196°) (Balard); (190°) (Balbiano, *J.* 1876, 348); (194°) (Kahlbaum). S.G. ^{0} ·870 (Balbiano). S.V. 244·5. V.D. 6·1. Smells, when dissolved in alcohol (7 pts.), like apples.

Octyl ether $C_8H_{17}A'$. (250°). S.G. ^{12} ·862 (Zincke, *A.* 152, 6).

Cetyl ether $C_{16}H_{33}A'$. [25°]. (280°–290°) at 202 mm. S.G. ^{22} ·852 (Dollfus, *A.* 131, 283).

Allyl ether C_3H_5A'. (154°). Oil (Cahours a. Hofmann, *A.* 108, 296).

Glyceryl derivative v., GLYCERIN.

Chloride $Pr.CH_2.COCl$. (114°) at 726 mm. S.G. $\frac{20}{4}$ ·9887. μ_β 1·4213. R_∞ 49·14. Liquid, easily decomposed by water (Béchamp, *C. R.* 42, 224; Brühl, *A.* 203, 24).

Bromide C_5H_9OBr. (143°). Liquid.

Iodide C_5H_9OI. (168°) (Cahours, *C. R.* 44, 1252).

Anhydride $(C_5H_9O)_2O$. Mol. w. 186. (215°) (Chiozza, *A.* 84, 106). Converted by hydrated BaO_2 into the oily peroxide $(C_5H_9O)_2O_2$ (Brodie, *Pr.* 12, 655).

Aceto-valeric anhydride $(C_5H_9O).OAc$. (147°–160°) (Autenrieth, *B.* 20, 3187).

Amide $C_4H_9.CONH_2$. [128°] (Letts, *B.* 5, 669; Hofmann, *B.* 15, 982); [135°] (Schmidt a. Sachtleben, *A.* 193, 102). (231°). Silky plates, v. sol. water and alcohol.

Anilide $C_4H_9.CO.NHPh$. [115°] (Chiozza, *A. Ch.* [3] 39, 201; Kelbe, *B.* 16, 1200; *cf.* Dumas, *C. R.* 25, 475, 658; Dessaignes, *A.* 68, 333). Sl. sol. hot water, v. sol. alcohol and ether.

Nitrile $Pr.CH_2.CN$. *Isobutyl cyanide.* Mol. w. 83. (129°) (R. Schiff, *B.* 19, 567). S.G. ^{0} ·823. V.D. 2·89. Formed by heating ammonium valerate or valeramide with P_2O_5 (Dumas, Malaguti a. Leblanc, *C. R.* 25, 658). Occurs among the products of oxidation of gelatin and caseïn by chromic acid mixture (Schlieper, *A.* 59, 15; Guckelberger, *A.* 64, 72), of the action of chlorine on leucine (Schwanert, *A.* 102, 228), and of the action of conc. HNO_3 on castor oil (Hell a. Kitrosky, *B.* 24, 980). Formed also, together with valeramide, by heating valeric acid with potassium sulphocyanide (Letts, *B.* 5, 669). It is also got by the action of cold Ac_2O on the oxim of valeric aldehyde (Dollfus, *B.* 25, 1915). Prepared by digesting isobutyl iodide with KCy and alcohol (Erlenmeyer a. Hell, *A.* 160, 266). Liquid, smelling like almonds, dissolving in about four times its volume of water

Sodium converts it, on heating, into **cyanbutine** $C_{15}H_{27}N_3$, crystallising in stellate groups of needles, which yield B'HCl and $B'_2H_2PtCl_6$, and is converted by nitrous acid into $C_{15}H_{26}(OH)N_2$ [89°] (E. von Meyer, *J. pr.* [2] 37, 407).

Active valeric acid $CHMeEt.CO_2H$. *Methyl-ethyl-acetic acid. Hydrotiglic acid.* (177° i.V.). S.G. $\frac{24}{175}$ ·938 (Saur). S.V. 129·1 (Lossen, *A.* 254, 60). Occurs in the essential oil from the fruit of *Angelica Archangelica* (R. Müller, *B.* 14, 2476).

Formation.—1. By oxidation of isoamyl alcohol.—2. By reducing tiglic acid with HI and P (Schmidt a. Berendes, *A.* 191, 117).—3. By heating methyl-ethyl-malonic acid (Bischoff a. Conrad, *A.* 204, 151).—4. From methyl-ethyl-acetoacetic ether (Saur, *A.* 188, 257).—5. By reducing angelic acid (Schmidt, *A.* 208, 261).—6. By reducing bromo-hydro-tiglic acid (Pagenstecher, *A.* 195, 121).—7. By the action of NaOEt and EtI on propionyl-propionic acid (Israel, *A.* 231, 219).—8. By oxidation of the corresponding aldehyde (Lieben a. Zeisel, *M.* 7, 56).

Properties.—The acid obtained by synthetic methods is inactive, but when obtained by oxidation of active amyl alcohol it is dextrorotatory, but is mixed with inactive isovaleric acid. By oxidation of an amyl alcohol $[\alpha]_D = -4·4°$ Guye and Chavanne (*C. R.* 116, 1454) obtained a valeric acid (174°), $[\alpha]_D = +13·6°$, S.G. $\frac{22}{22}$ ·938. By oxidation of an amyl alcohol $[\alpha]_D = -5·2°$ at 22° Rogers (*C. J.* 63, 1130) got a valeric acid (175°), S.G. $\frac{22}{22}$ ·936, $[\alpha]_D = +13·9°$ at 22°. Methyl-ethyl-acetic acid can be separated from isopropyl-acetic acid through the greater solubility of its silver salt. Dilute $KMnO_4$ oxidises methyl-ethyl-acetic acid to $CMeEt(OH).CO_2H$.

Salts.—CaA'_2 5aq: needles. S. (of CaA'_2)).—BaA'_2: gummy mass.—ZnA'_2. Needles, ore sol. cold than hot water.—CuA'_2: bluish-een, crystalline pp.—AgA': groups of needles. 1·13 at 20° (C. a. B.); 1·11 at 1° (Sedlitzky, . 8, 568).

Ethyl ether EtA'. (133·5° i.V.). S.G. $\frac{1}{0}$ ·8695.

Nitrile $C_5H_{11}N$. (125°). S.G. ^{0} ·8061. ormed by adding Na and EtI to a solution of cetonitrile in benzene (Hanriot a. Bouveault, *l.* [2] 51, 173). Liquid.

Valeric acid $CMe_3.CO_2H$. *Tri-methyl-acetic cid.* [35°]. (163·5° i.V.). S.G. ^{50} ·905. S. 2·2 ; 20°. *Heat of neutralisation*: Gal a. Werner, *l.* [2] 46, 801. Formed by heating its nitrile ith alcoholic potash or conc. HClAq at 00° (Butleroff, *A.* 165, 322; 170, 151; 173, 355; . 5, 478). Formed also by action of CrO_2 on inacolin (Friedel a. Silva, *B.* 6, 146, 826) and n tri-methyl-pyruvic acid (Glücksmann, *M.* 10, 77). Monometric crystals. Does not yield a romo- derivative on heating with Br, either lone or in presence of P (Reformatzky, *B.* 23, 596).

Salts.—NaA' 2aq. Prisms, v. sol. water.—$H_2A'_2$. Needles, m. sol. water.—CaA'_2 5aq.—aA'$_2$ 4aq. S. 7 at 1°.—SrA'_2 5aq.—BaA'_2 5aq. . 34 at 2° (Landau, *M.* 14, 707).—MgA'_2 8aq. -ZnA'_2 aq. S. (of ZnA'_2) 1·7 at 20°. The cold aturated solution becomes filled on warming with a solid salt, which dissolves up again on cooling.—PbA'_2.—$PbHA'_3$: needles.—CuA'aq: greenish pp.—AgA'. S. 1·1 at 1°; 1·27 at 27° (Stiassny, *M.* 12, 599).

Methyl ether MeA'. (101°) (Butleroff).

Ethyl ether EtA'. (118·5° i.V.). S.G. ^{0} ·875.

Tert-butyl ether C_4H_9A'. (135° i.V.).

Amyl ether $CMe_3.CH_2A'$. (165°) (Tissier, *Bl.* [2] 24, 558).

Chloride $CMe_3.COCl$. (106°).

Anhydride $(CMe_3.CO)_2O$. (190°).

Amide $CMe_3.CO.NH_2$. [154°]. (212°). Formed by heating the ammonium salt in sealed tubes at 230° (Franchimont a. Klobbie, *R. T. C.* 6, 238). Long needles. Decomposed by pure HNO_3 (S.G. 1·53), with evolution of N_2O.

Methylamide $CMe_3.CO.NHMe$. [91°]. (204°).

Dimethylamide $CMe_3.CO.NMe_2$. (186°).

Ethylamide $CMe_3.CO.NHEt$. [49°]. (204°).

Diethylamide $CMe_3.CO.NEt_2$. (203°). S.G. ^{15} ·891.

Nitrile $CMe_3.CN$. *Tert-butyl cyanide.* [16°]. (106°). Formed, together with a **polymeride** (160°), by the action of tert-butyl iodide on dry potassio-mercuric cyanide below 5° (Butleroff, *A.* 170, 151; Freund a. Lenze, *B.* 23, 2866; 24, 2161). Crystalline mass with pungent smell. On heating with aniline hydrochloride it yields phenyl-valeramidine, which forms an oxalate [192°]. Hydroxylamine forms the amidoxim $CMe_3.C(NH_2):NOH$ [116°].

References.—Amido-, Bromo-, Chloro-, Iodo-, Nitro-, Nitroso-, and Oxy- valeric acids.

***n*-VALERIC ALDEHYDE**

$CH_3.CH_2.CH_2.CH_2.CHO$. (103°). S.G. ^{11} ·819. Formed by distilling calcium *n*-valerate with calcium formate (Lieben a. Rossi, *A.* 159, 70; Zander, *A.* 224, 81).

Isovaleric aldehyde $(CH_3)_2CH.CH_2.CHO$. *Valeral.* Mol. w. 86. (92·5°). S.G. $\frac{15}{15}$ ·8041; $\frac{25}{25}$ ·7981 (Perkin, *C. J.* 45, 477). μ_β 1·3934. R_∞ 40·66 (Brühl). V.D. 43·06 (calc. 43) (Schröder, *B.* 4, 400, 468). S.V. 118·5. Formed by oxidation of isoamyl alcohol (Dumas a. Stas, *A. Ch.* [2] 73, 145; Parkinson, *A.* 90, 114; Kolbe a. Guthrie, *A.* 109, 296). Formed also by distilling calcium iso-valerate with calcium formate (Limpricht, *A.* 97, 370), by the distillation of isovalerates (Chancel, *A.* 60, 318; Ebersbach, *A.* 106, 262; Schmidt, *B.* 5, 600), by oxidation of gluten (Keller, *A.* 72, 34) and castor oil (Arzbächer, *A.* 73, 202), and by the action of SO_3 on leucine (Schwanert, *A.* 102, 226).

Properties.—Neutral oil, with pungent fruity odour. Polymerises on keeping. Mixes with alcohol and ether. On heating with ammonium sulphocyanide it yields a dark-red liquid, sol. alcohol, ether, and HOAc (Brodsky, *M.* 8, 37). Alkaline sodium nitroprusside gives a violet-red colour, destroyed by HOAc (Von Bitto, *A.* 267, 376). Combines with sodium bisulphite, forming $(C_5H_{10}O)NaHSO_3$.

Reactions.—1. Readily oxidised to valeric acid.—2. *Chlorine* forms mono- and di- chloro-valeric aldehydes, and, at 140°, oily $C_{10}H_{12}Cl_4O$ (204°), which is converted by alcoholic soda into $C_{10}H_{10}Cl_4O$ (209°).—3. PCl_5 forms $C_5H_{10}Cl_2$.—4. *Potash-fusion* gives valeric acid.—5. Heating with *lime* forms isoamyl alcohol, calcium valerate and other bodies (Fittig, *A.* 117, 68).—6. *Sodium-amalgam* and water slowly form isoamyl alcohol (Wurtz, *A.* 134, 201).—7. *Sodium* forms isoamyl alcohol, sodium valerate, decyl alcohol $C_{10}H_{22}O$ (203°), an oil $(C_{10}H_{18}O)_n$ (250°–290°), the compound $C_{20}H_{38}O_3$, and the acid $C_{10}H_{18}O_2$ (Borodin, *Z.* 1864, 353; *B.* 5, 480).—8. KOH at 0° produces an oily polymeride, lighter than water, not capable of combining with $NaHSO_3$, and yielding isovaleric aldehyde and the compounds $C_{10}H_{18}O$ and $C_{20}H_{38}O_3$ on distillation (Borodin, *B.* 6, 982). This polymeride, left in contact with Na_2CO_3Aq, often forms needles of $C_{20}H_{42}O_5$ [70°].—9. Heating with KOH forms the aldehyde $C_{10}H_{18}O$ and a compound $C_{20}H_{38}O_3$ (260°–290°). S.G. ·90.—10. Heating with *zinc* at 180° forms decenoic aldehyde $C_{10}H_{18}O$ (190°), S.G. ^{0} ·862 (Riban, *C. R.* 75, 96; Kekulé, *A.* 162, 77) and other products.—11. $ZnEt_2$ produces the oil $(C_{10}H_{18}O)_n$ in large quantity (Beilstein a. Rieth, *A.* 126, 242). $ZnMe_2$, followed by water, forms methyl-isobutyl-carbinol (Kuvsinoff, *J. R.* 1887, 204).—12. Dry K_2CO_3 at 50° forms an oily polymeride, which is reconverted at 180° into the aldehyde. Boiling with K_2CO_3 yields $C_{10}H_{18}O$ (*v. supra*), $C_{20}H_{38}O_3$ (265°–270°), and $C_{15}H_{28}O_2$ (235°–240°) (Gäss a. Hell, *B.* 8, 369).—13. Dry K_2CO_3 added to moist isovaleric aldehyde forms, after some days, crystals of a polymeride [84°], which is reconverted at 108° into the original aldehyde (Bruylants, *B.* 8, 414).—14. PH_4I forms a compound $(C_5H_{10}O)_4PH_4I$, crystallising from ether in plates [119°], converted by cold potash into $(C_5H_{10}O)_3PH_4.OH$, crystallising in prisms [125°], insol. water (De Girard, *A. Ch.* [6] 2, 33; *C. R.* 94, 215).—15. On heating with *hypophosphorous acid* in an atmosphere of hydrogen the compound $(C_5H_{10}O)_2H_3PO_2$ [160°] is formed. It yields BaA'_2 aq (Ville, *C. R.* 109, 71).—16. AcCl at 100° combines, forming chloro-amyl acetate $C_4H_9.CHCl.OAc$ (Maxwell Simpson, *Pr.* 27, 120). 17. *m-Amido-benzoic acid* forms $C_{12}H_{15}NO_2$ [c. 230°].—18. Dry HCl forms $(C_4H_9.CHCl)_2O$ (180°) (Bruylants, *B.* 8, 414).—19. Conc. NH_3Aq forms isovaleric aldehyde-ammonia $C_4H_9.CH(NH_2)OH$ 7aq [58°] (Erdmann, *A.* 130, 211; Petersen, *A.* 132, 158; Ljubavin, *B.* 6, 1460), which yields, on allowing its alcoholic solution to stand, or on boiling with potash, the oily 'trioxyamylamine' $C_{15}H_{33}NO_3$, forming B'HCl [113°] and $B'_2H_2PtCl_6$. $AgNO_3$ reacts with isovaleric aldehyde-ammonia, forming $(C_5H_{11}N)_2AgNO_3$ and $(C_5H_{11}N)_3AgNO_3$ (Goldschmidt, *B.* 11, 1200; Mixter, *J.* 1878, 438).—20. Alcoholic NH_3 at 150° forms valeritrine, hydrovaleritrine, and other bodies. Valeritrine $C_{15}H_{27}N$ is a very unstable liquid (250°–260°), yielding $B'HHgCl_3$ [88°], $B'_2H_2PtCl_6$, and $B'C_6H_3N_3O_7$ [130°]. Hydrovaleritrine $C_{15}H_{29}N$ or $C_{15}H_{31}N$ is a liquid, yielding crystalline B'HCl: S. 2·87 at 22°, not melted at 180° (Ljubavin, *B.* 6, 565).—21. H_2S passed into an aqueous solution forms thiovaleric aldehyde $C_5H_{10}S$ [69°]. An isomeride (115°) is got, together with a polymeride [94·5°], by heating isovaleric aldehyde with sulphur at 250° (Barbaglia, *B.* 13, 1574; 17, 2654; *G.* 11, 95; 16, 426).—22. CS_2 and NH_3Aq form carbovaleraldine $C_{11}H_{22}N_2S_2$ (Schröder, *B.* 4, 469; Mulder, *A.* 168, 237), which melts at 109° (Guareschi, *A.* 222, 311).—23. $NH_2.CS.OEt$ and HCl form $C_5H_{10}(NH.CS.OEt)_2$ [108°] (Bischoff, *B.* 7, 1078).—24. H_2Se passed into an aqueous solution of valeric aldehyde forms $C_5H_{10}Se$ [56·5°].—25. *Acetone* and dilute NaOH yield $PrCH_2.CH{:}CH.CO.CH_3$ (180°) (Barbier a. Bouveault, *C. R.* 118, 198).

Oxim $C_4H_9.CH{:}NOH$. Mol. w. 101. (163°). S.G. $\frac{20}{4}$ ·8934 (*in vacuo*). μ_D 1·437 (Petraczek, *B.* 16, 829; Trapesonzjanz, *B.* 26, 1428). It is a *syn*- oxim, because it yields valeronitrile when mixed with Ac_2O and ether (Dollfus, *B.* 25, 1915).

Isovaleric orthaldehyde. *Amylidene glycol.*

Acetyl derivative $C_4H_9.CH(OAc)_2$. (195°). Formed by heating isovaleric aldehyde with Ac_2O at 200°.

Benzoyl derivative $C_4H_9.CH(OBz)_2$. [111°]. (264°). Formed by heating the aldehyde with Bz_2O at 260° (Guthrie a. Kolbe, *A.* 109, 298).

Di-methyl ether $C_4H_9.CH(OMe)_2$. (124°). S.G. ^{10} ·852. Formed from isovaleric aldehyde (2 vols.), MeOH (5 vols.), and HOAc (1 vol.) (Alsberg, *J.* 1864, 486).

Di-ethyl ether $C_4H_9.CH(OEt)_2$. (168°). S.G. ^{12} ·835. Formed in like manner.

Di-isoamyl ether $C_4H_9.CH(OC_5H_{11})_2$. (c. 248°). S.G. ^{7} ·849.

Ethyl isoamyl ether $C_4H_9.CH(OEt)(OC_5H_{11})$. (c. 205°). S.G. ^{12} ·875. Formed by the action of Na on an ethereal solution of isovaleric ether (Greiner, *Z.* 1866, 465).

Valeric aldehyde $CHMeEt.CHO$. (91°). Formed by reducing tiglic aldehyde with iron and HOAc (Herzig, *M.* 3, 123; Lieben a. Zeisel, *M.* 7, 56), and by warming $CH_2{:}CH.CHEt.OH$ with dilute (1 p.c.) H_2SO_4 (Kondakoff, *J. R.* 20, 154).

Valeric aldehyde $CMe_3.CHO$. [3°]. (75°). S.G. ^{18} ·7927 (Tissier, *Bl.* [2] 24, 558).

Di-isovaleric aldehyde *v.* DECENOIC ALDEHYDE.

Reference.—DI-BROMO-, CHLORO-, IODO-, and OXY- VALERIC ALDEHYDE.

VALEROGUANAMINE $C_7H_{13}N_5$ *i.e.* $\left.\begin{array}{r}\mathrm{PrCH_2.C{:}N.C(NH)}\\ \mathrm{NH.C(NH)}\end{array}\right>\mathrm{NH}$. *Butylguanamine.* [173°]. Formed by heating guanidine isovalerate (Bandrowski, *B.* 9, 240; Haaf, *J. pr.* [2] 43, 76). Flat plates (from water). Weak base.—B'HCl: needles, v. sol. water.—$B'H_2SO_4$.—$B'AgNO_3$.

VALEROLACTIDE *v.* OXY-VALERIC ACID.

VALEROLACTONE *v.* OXY-VALERIC ACID.

VALERONE *v.* DI-ISOBUTYL KETONE.

VALERONITRILE *v.* *Nitrile* of VALERIC ACID.

VALEROVALERIC ACID *v.* VALERYL-VALERIC ACID.

DIVALERYL $C_{10}H_{18}O_2$ *i.e.* $C_4H_9.CO.CO.C_4H_9$. (270°–280°). Formed by the action of Na on valeryl chloride (Brühl, *B.* 12, 315). Oil.

VALERYL-ACETOPHENONE *v.* PHENYL BUTYL METHYLENE KETONE.

VALERYL CHLORIDE *v.* *Chloride* of VALERIC ACID.

VALERYL-CYANAMIDE *v.* CYANIC ACIDS.

VALERYLENE *v.* PENTINENES and also BROMO- and DI-CHLORO-VALERYLENE.

VALERYLENE TETRABROMIDE *v.* TETRA-BROMO-PENTANE.

VALERYLENE HYDRATE *v.* PENTENYL ALCOHOL.

VALERYLENE HYDROCHLORIDE *v.* CHLORO-AMYLENE.

VALERYL-VALERIC ACID. *Ethyl ether* $C_{12}H_{22}O_3$ *i.e.* $CH_2Pr.CO.CHPr.CO_2Et$. (206°) at 722 mm. Formed by the action of sodium on isovaleric ether (Greiner, *Z.* 1866, 461; Wohlbruck, *B.* 20, 2335). Oil, sol. alcohol and ether.

VALYLENE C_5H_6. Mol. w. 66. (50°). A product of the action of alcoholic potash on valerylene dibromide (Reboul, *A.* 135, 372). Liquid, with odour of garlic and prussic acid. Ammoniacal Cu_2Cl_2 ppts. yellow C_5H_5Cu, which yields the pure hydrocarbon on treatment with dilute HClAq. Bromine at 0° forms crystalline $C_5H_6Br_4$. Ammoniacal $AgNO_3$ yields a white pp. of C_5H_5Ag.

VANADATES *v.* VANADIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, p. 851.

VANADIC ACIDS *v.* VANADIUM OXYACIDS, p. 851.

VANADIUM. V. At. w. 51·2. Mol. w. not known. Melts at a very high temperature; probably higher than m.p. of Mo, which does not melt at 1700°–1800° (Moissan, *C. R.* 116, 1225). S.G. 5·5 at 15° (Roscoe, *T.* 1869. 679). For emission-spectrum, obtained by using electric sparks, *v.* Thalén (*A. Ch.* [4] 18, 243)

Historical.—In 1801 Del Rio announced the discovery of a new metal in a lead ore from Zimapan in Mexico (*G. A.* 71, 7); to this metal he gave the name *erythronium*, but at a later time he thought the metal was only impure chromium. In 1830 Sefström found a new element in the bar-iron and refinery slags where iron-ore from Taberg in Sweden was smelted (*P.* 21, 43); this element he called *vanadium* (from a Scandinavian deity *Vanadis*). In the same year (*P.* 21, 49) Wöhler found that the lead ore examined in 1801 by Del Rio contained lead vanadate; and he showed that the metal which Del Rio had called erythronium, and had then supposed to be impure chromium, was really vanadium. In 1831 Berzelius supposed he had prepared vanadium by heating an oxychloride in NH_3, and also by heating the highest oxide with K (*P.* 22, 1); but in 1867 Roscoe (*T.* 1868. 1; 1869. 679; *v.* also 1870. 317) showed that one of the substances which until then had been taken to be the element V was a nitride, and that another substance, taken to be V, was an oxide of this element. Roscoe obtained pure V by heating VCl_2 to redness for many hours in dry H. Roscoe was led to doubt the accuracy of the statement of the properties and at. w. of V that had been accepted on the authority of Berzelius, because he found that several compounds of V and Pb were isomorphous, but that it was impossible to assign comparable formulæ to these compounds if the at. w. given by Berzelius for V were accepted (*v. T.* 1868. 1 *et seq.*). Berzelius gave the value 68·5 to the at. w. of V; he assigned the formulæ VO, VO_2, and VO_3 (O = 8) to the three oxides, and classed V with Cr, Mo, and W. Roscoe's researches showed that the at. w. of the metal is 51·2, that the oxides are best represented as V_2O_3, V_2O_4, and V_2O_5, that the substance thought to be V was really chiefly V_2O_2, that the compound supposed by Berzelius to be VCl_3 was $VOCl_3$, and that V must be classed with P and As.

Occurrence.—Small quantities of compounds of V are found fairly widely distributed; the element does not occur uncombined. The chief minerals that contain V compounds are *mottramite* (Cu-Pb vanadate), *descloizite* (Pb-Zn vanadate), *dechenite* (Pb-Zn-Cu vanadate), *roscoeite* (Al vanadate with K silicate), *vanadinite* (vanadate of lead with lead chloride), and some other minerals, which generally contain vanadates of Cu, Pb, Zn, or Ca. Small quantities of compounds of V are found in all *pisolitic limonites* (Böttger, *C. C.* 1873. 514), in some *pitchblendes*, *clays*, and *basalts*, and in a few other rocks. Compounds of V have also been found, in small quantities, in the slag from copper extraction works (Karsten, *P.* 52, 629; Witz a. Osmond, *Bl.* [2] 38, 49); in many specimens of pig-iron (*v.* Riley, *C. J.* 17, 21; *cf.* Hodges, *C. N.* 26, 238; Walz, *Am. Ch.* 6, 453); in some meteorites (*v.* Apjohn, *C. J.* 27, 104); in caustic soda and sodium phosphate (Schöne a. Rammelsberg, *B. B.* 1864. 681; Donath, *D. P. J.* 240, 318); and, according to Lockyer (*Pr.* 27, 279), probably in the sun.

Preparation.—1. From the refinery slag of the Taberg iron-ore. The finely-powdered slag is heated with KNO_3 and Na_2CO_3, the fused substance is digested with boiling water, and solution of a salt of Ba or Pb is added to the filtered liquid; the ppd. Ba or Pb vanadate is decomposed by boiling with a slight excess of H_2SO_4Aq, and the solution is filtered from $BaSO_4$ or $PbSO_4$; the filtrate is neutralised by NH_3Aq and concentrated, and pieces of NH_4Cl are placed in the liquid until some NH_4Cl remains undissolved; the NH_4VO_3 which is thus ppd. as a white crystalline powder is washed with conc. NH_4ClAq, and then with alcohol, and is then decomposed by heating strongly in an open vessel, whereby V_2O_5 is produced (Berzelius, *P.* 22, 1). Wöhler (*A.* 78, 125) employed a very similar process for preparing V_2O_5 from *limonite*.—2. From vanadinite. L'Hôte (*C. R.* 101, 1151) recommends to mix finely-powdered *vanadinite* (approximately $3Pb_3V_2O_8.PbCl_2$) with four times its weight of lampblack and a little oil, to heat strongly in a closed vessel, and then to heat to 300° in a stream of dry Cl, whereby $VOCl_3$ is formed, and distilled over into a cooled U-tube; other compounds of V are readily prepared from $VOCl_3$.—3. From the cobalt-ore of Mottram in Cheshire. This source of V compounds was discovered by Roscoe (*v. C. J.* [2] 6, 326). The Cheshire Keuper sandstone contains carbonates of Cu, carbonate of Pb and *galena*, *black cobalt-ochre*, iron oxides, and salts of As, Ag, Mn, and Ba. The compound of V was probably *vanadinite*. The sandstone was crushed, and the metallic compounds were dissolved by HClAq; bleaching-powder and milk of lime were added till the reaction was alkaline; and it was from the pp. thus obtained that Roscoe prepared V and its compounds. The lime pp. contained chiefly As, Cu, Fe, Pb, V, and Ca in combination with SO_4 and PO_4; it was heated in a furnace with ground coal to remove As, then roasted with a quarter its weight of Na_2CO_3

and lixiviated with water; the solution was saturated with H_2S and filtered, and H_2S was boiled off; crude oxide of V was then ppd. by NH_3Aq; the oxide was dried and heated with conc. HNO_3Aq to oxidise it to vanadic acid, which was then boiled with saturated $(NH_4)_2CO_3Aq$, and the somewhat soluble NH_4 vanadate was crystallised from water, and then strongly heated in an open vessel; the V_2O_5 thus obtained was suspended in water into which NH_3 was passed; the solution of NH_4 vanadate was filtered from silica, phosphates, &c., evaporated to dryness, and heated in an open vessel until V_2O_5 remained.

The metal vanadium is prepared by reducing VCl_2 in H (for preparation of VCl_2 *v.* VANADIUM DICHLORIDE, p. 844). The process is conducted in perfectly pure and dry H; every trace of moisture and air must be excluded. The pure and dry H is passed for 12 hours through a porcelain tube, connected (by specially arranged paraffin-joints) by a glass tube to the H apparatus; the VCl_2 is then placed in the porcelain tube (a special arrangement for doing this is described by Roscoe), and H is passed through the apparatus for 6 hours. The porcelain tube is then gradually heated to full redness, and the passage of H is continued so long as HCl is given off, after which the tube is allowed to cool for several hours in the stream of H. The process occupies from 40 to 80 hours according as from 1 to 4 g. of VCl_2 are used. The V thus obtained contains traces of H and O. Reduction proceeds more quickly at a white heat, but the product is not so pure; it generally contains c. 95 to 96 p.c. V. (For details, and figures of the apparatus, *v.* Roscoe, *T.* 1869. 679; 1870. 317; or *C. J.* [2] 8, 344; 9, 23.)

Moissan (*C. R.* 116, 1225) obtained V containing from 17·5 to 25·7 p.c. C, by heating a mixture of C and one of the oxides of V in an electric furnace, using a current of 70 volts and 1,000 ampères; with a current of 70 volts and 850 ampères reduction proceeded very slowly.

Vanadium, mixed with V_2O_3, was obtained by Roscoe (*l.c.*) by strongly heating a mixture of one of the chlorides of V with Na in an atmosphere of H, and lixiviating with water; the admixed black, powdery V_2O_3 can be removed from the heavier, grey, lustrous, metallic powder, by repeated washings with water, and a substance containing c. 91 p.c. V can be obtained.

The substance supposed by Berzelius (*P.* 22, 1) to be V, and obtained by heating V_2O_5 with K, was shown by Roscoe to consist chiefly of V_2O_2. The black powder which Uhrlaub (*P.* 103, 134) prepared by heating V oxychloride in NH_3, and which he supposed to be V, was found by Schafarik (*W. A. B.* 33, 5) to be VN_2 (*cf.* Roscoe, *l.c.*).

Properties.—A light-grey, lustrous powder; under the microscope it is seen to be composed of crystalline, silver-white particles. Does not become coherent and dense when strongly compressed. S.G. 5·5 at 15°. Not magnetic. Is not oxidised in air at the ordinary temperature, nor by moistening and then drying *in vacuo*. Has not been melted, except perhaps when reduced from the oxides by C in an electric furnace (*v.* Moissan, *C. R.* 116, 1225). When powdered V is thrown into a Bunsen flame it burns brilliantly; when strongly heated in O it forms V_2O_5; and when slowly heated in air it perhaps forms V_2O, then V_2O_3, V_2O_4, and finally V_2O_5. Burns in Cl, forming VCl_4; combines with N to form VN; also combines with S. V is insoluble in HClAq; it dissolves in hot conc. H_2SO_4 and in HNO_3Aq. V dissolves in molten NaOH, giving off H, and forming a vanadate. V acts on glass vessels in which it is heated, forming a compound with Si; it also alloys with Pt (R., *l.c.*).

The at. w. of V has been determined (1) by reducing V_2O_5 to V_2O_3 by heating in H (Berzelius, *P.* 22, 15 [1831]; Roscoe, *T.* 1868. 8); (2) by oxidising V_2O_3 to V_2O_5 by HNO_3 (B., *l.c.* [1831]); (3) by analysing $(V_2O_2)(SO_4)_2.4H_2O$ (B., *l.c.*, p. 18 [1831]); (4) by ppg. $VOCl_3$ by $AgNO_3Aq$, removing excess of Ag from the filtrate, evaporating to dryness, heating, and weighing the V_2O_5 produced (B., *l.c.* [1831]); (5) by determining the weight of Ag required to ppt. the Cl from $VOCl_3$; also by weighing the AgCl ppd.; also by filtering from AgCl, evaporating, and weighing the V_2O_5 obtained (Roscoe, *T.* 1868. 23); (6) by determining V.D.s of, and analysing, VCl_4 and $VOCl_3$ (*q. v.*). The results obtained by Berzelius (with the necessary corrections on account of the wrong formulæ used by him; *v.* Roscoe, *l.c.*) gave values for at. w. of V varying from 49·3 to 52·5; Roscoe's values from the reduction of V_2O_5 to V_2O_3 varied from 51·13 to 51·55, and from the analyses of $VOCl_3$ from 50·32 to 51·877. The S.H. of V has not been determined.

Vanadium is both metallic and non-metallic in its reactions. V_2O_4 interacts with strong acids to form divanadyl salts, $V_2O_2(SO_4)_2$, &c.; hypovanadates $V_4O_7(OM)_2$ are also derived from a hydrate of V_2O_4; V_2O_5 interacts with conc. H_2SO_4 to form $V_2O_5.3SO_3$ and $V_2O_5.2SO_3.xH_2O$; V_2O_5 also forms $V_2O_5.H_2O$ (=HVO_3) and $V_2O_5.2H_2O$ (=$H_4V_2O_7$), which react as acids, and salts of the acid H_3VO_4 are also known; V_2O_5 also combines with various acidic oxides (P_2O_5, MoO_3, &c.) and basic oxides, to form complex, salt-like compounds. The sulphides of V dissolve in alkali sulphide solutions; several thiovanadates have been isolated, *e.g.* $(NH_4)_3VS_4$; and also thio-oxyvanadates, *e.g.* Na_3VS_3O. The haloid compounds of V are generally decomposed by water to oxyhaloid compounds.

Vanadium is placed in Group V., with N, P, As, Nb, Sb, Di, Er, Ta and Bi. V is the second member of the even series family of this group, the family consisting of N, V, Nb, Ta and an unknown element with an at. w. between those of Th (=232) and U (=239). Group V does not show a marked division into families; the gradation of properties from N to Bi is fairly regular, nevertheless the families (1) N and P, (2) V, Nb and Ta, (3) As, Sb and Bi are distinctly indicated. No hydrides of members of the vanadium family have been isolated with certainty. The highest oxides, M_2O_5, are salt-forming; all of them interact with alkalis to form salts containing the elements M in the acidic radicles; V_2O_5 also forms basic salts $(VO)_xR_y$, with strong acids; normal salts have not been obtained by the reactions of M_2O_5 with acids. Oxyacids of V, viz. HVO_3 and $H_4V_2O_7$, have been isolated, but definite oxyacids of Nb and Ta are unknown. Both Nb and Ta form chlorides, corresponding with their highest oxides M_2O_5; but the highest haloid compound of V is VX_4, corresponding with V_2O_4; oxyhaloid compounds of V of the form of VX_3 exist ($VOCl_3$, $VOBr_3$) (*v.* Nitrogen group of elements, vol. iii. p. 571).

In considering the relations between vanadium and the elements of Group V., the position of V in series 4 must be taken into account: as compared with the elements that form series 3, in which series P is placed, the elements of the vanadium series are metallic (V is preceded by Ti, Sc, Ca and K, and is followed by Cr, Mn, and the iron elements); the elements of the vanadium series are nearly as metallic, and also as non-metallic, as Rb, Sr, Y, Nb, Mo, —, and the Ru metals, which elements form series 6, *i.e.* the niobium series. Hence V would be expected to be distinctly more like a metal, in its chemical relations, than P, and about equal to Nb in its metallic and non-metallic tendencies. As V is the second member of the even series family of Group V., it might be expected to resemble N, which is the first of the even series elements of this group; but it is to be remembered that the differences between the first and second even series members of the groups (*i.e.* the differences between Li and K, Be and Ca, B and Sc, C and Ti, N and V, O and Cr, F and Mn), become more marked in passing from Group I. to Group VII., and it is also to be remembered that the resemblances between the first even series members and the succeeding odd series members, become more marked as the atomic weights increase; F is more like Cl and Br than O is like S, Se, and Te; but O resembles S, Se, and Te more than N resembles P, As, Sb, &c.; and C is more like Si, Ge, Sn, &c., than B is like Al, Ga, In, &c.; but C less resembles Si, &c., than N resembles P, &c.

Reactions and Combinations.—(Roscoe, *T.* 1869. 679; 1870. 317.) 1. Heated in *air*, V burns to V_2O_5; lower oxides are first formed if the temperature is low.—2. Does not decompose *water* at 100°.—3. Heated to redness in *chlorine* burns to VCl_4; heated in *bromine* produces VBr_3; does not combine with *iodine*.—4. Heated with excess of *sulphur*, V forms V_2S_3 (*v.* Kay, *C. J.* 37, 728).—5. Heating in a stream of pure *nitrogen* produces VN.—6. V combines directly with *silicon* and also with *platinum*.—7. *Molten potash* or *soda* dissolves V, forming an alkali vanadate and giving off H.—8. V dissolves in *conc. sulphuric acid* (? forming a vanadyl salt); also in *nitric acid*, probably forming a basic nitrate; also, slowly, in *hydrofluoric acid* (? forming VF_3).

Detection and Estimation.—Small quantities of compounds of V give a colourless borax or microcosmic salt bead in the outer flame, becoming green in the reducing flame; if much V compound is present the bead is yellow in the outer flame. Solutions of V_2O_5 in acids are not ppd. by H_2S, but are reduced to solutions of V_2O_2 which are lavender-blue; if reduction is effected by Zn, Cd, or Na-amalgam the liquid becomes green, then blue, and finally lavender-blue; after reduction the solution bleaches indigo very rapidly, and soon absorbs O. Solutions of vanadates, either neutral or acidified by acetic acid, give finely-divided black pps. with tincture of galls, and the liquids appear like ink. When an acidified solution of a vanadate is shaken with an ethereal solution of H_2O_2, the latter solution becomes dark red (Werther, *J. pr.* 88, 195).

Vanadium is generally estimated by converting it into an ammonium salt, strongly heating this in air, and either weighing the V_2O_5 thus produced or heating in H and weighing the V_2O_3 that remains. For a volumetric method of estimating V *v.* Gerlach (*B.* 10, 1216).

Vanadium, acids of, *v.* Vanadium oxyacids, and salts and derivatives thereof, p. 851.

Vanadium, bromides of. Only one bromide of V has been obtained.

Vanadium tribromide VBr_3. Mol. w. not known; from analogy of PBr_3, $AsBr_3$, &c., the formula VBr_3 is probably molecular. Formed by heating V or VN to redness in vapour of Br. Also by passing Br vapour over a mixture of V_2O_3 and C kept at a red heat; $VOBr_3$ is formed, then $VOBr_2$, and then VBr_3 sublimes (Roscoe, *T.* 1870. 317). Roscoe (*l.c.*) recommends to prepare VBr_3 by placing pure VN in a porcelain boat in a tube of hard glass, driving out all air by dry CO_2, then passing vapour of Br through the tube while that part where the boat is placed is heated to redness, when brown vapours are given off and condense on the cooler parts of the tube, and finally driving out all traces of Br by a stream of dry CO_2. VBr_3 is a greyish black, opaque, amorphous, very deliquescent solid; loses Br even in a sealed tube; heated gently in air gives V_2O_3, and at a higher temperature V_2O_5. Dissolves in water, without giving off any Br, forming a brown liquid which goes green on addition of a few drops of HClAq; this reaction is said by R. to be characteristic of a salt of V_2O_3.

Vanadium, chlorides of. Three chlorides have been isolated: VCl_2, VCl_3, and VCl_4. V burns when heated in Cl, forming VCl_4, and the other chlorides are formed by reducing VCl_4 by H. The V.D. of VCl_4 has been determined, and the formula VCl_4 is molecular; the formula VCl_3 is probably molecular, from the analogy of $AsCl_3$, PCl_3, $BiCl_3$, &c.; VCl_2, AsI_2, PI_2 and $BiCl_2$ are the only haloid compounds of the form MX_2 that have been isolated in Group V.; the mol. w.s of these compounds have not been determined.

Vanadium tetrachloride VCl_4. Mol. w. 192·68. Prepared by Roscoe (*T.* 1869. 691).

Formation.—1. V or VN is heated in Cl.—2. The vapour of $VOCl_3$, mixed with excess of Cl, is passed slowly over a long layer of sugar-charcoal heated to redness.

Preparation.—VN is heated to redness in a tube of hard glass, in a current of pure, dry Cl, which must be free from air. The first few drops of distillate are rejected, as they contain traces of $VOCl_3$ formed from traces of oxide in the nitride used. The dark-red liquid that is formed is saturated with dry Cl, then heated for some hours in a current of dry CO_2 in a vessel connected with an upright condenser, and then fractionated.

Properties and Reactions.—A thick, dark, brownish-red liquid; boils at 154° under 760 mm. pressure. S.G. 1·8584 at 0°, 1·8363 at 8°, 1·8159 at 30°. V.D. 98·1 at c. 200°. Does not solidify at any temperature above −18°. Slowly decomposes to VCl_3 and Cl at ordinary temperatures, more quickly when exposed to light, and rapidly when heated. Gives off white fumes in the air. Dissolves in water, forming a blue solution, which does not bleach; this solution is oxidised by $KMnO_4Aq$ to $HClAq$ and V_2O_5Aq, $2VCl_4$ taking up O. Reacts violently with alcohol and ether, forming deep-coloured liquids. When heated with Br in a sealed tube, VCl_3 is formed. VCl_4 does not combine with Cl to form a higher chloride. H_2S reacts with VCl_4 to form VCl_3, HCl, and S (Kay, *C. J.* 38, 736).

VANADIUM TRICHLORIDE VCl_3. Mol. w. not determined, but formula is probably molecular from analogy of PCl_3, $AsCl_3$, &c. Prepared by heating VCl_4 in a retort as long as Cl is given off, and heating the residual solid to 160° in a stream of dry CO_2 (Roscoe, *T.* 1869. 691). Also by heating pure V_2S_3 in a stream of dry, air-free Cl, separating S_2Cl_2 by repeatedly distilling the liquid product, and heating the residue at 140° in dry CO_2 to remove the last traces of S_2Cl_2 (Halberstadt, *B.* 15, 1619). Lustrous, peach-blossom coloured tablets, resembling $CrCl_3$; S.G. 3·0 at 18°. Deliquesces very rapidly in air to a brown liquid, which goes green on addition of a drop or two of HClAq; this solution is oxidised by $KMnO_4Aq$, $2VCl_3$ taking up 2O, to HClAq and V_2O_5Aq. Soluble in alcohol and in ether. Heated in air forms V_2O_5. Heated in H is reduced to VCl_2 and then, gradually, to V.

VANADIUM DICHLORIDE VCl_2. Mol. w. not known. Formula possibly V_2Cl_4. Prepared by passing vapour of VCl_4, mixed with a large excess of pure, dry H, through a glass tube heated to dull redness. The distillation of VCl_4 should be slow, and the mixture of vapour of VCl_4 and H should be brought at once into the heated part of the tube. Forms apple-green, micaceous, hexagonal plates; S.G. 3·23 at 18°; very hygroscopic. Dissolves in water, forming a violet solution, which bleaches indigo and litmus, and reacts as a solution of a salt of V_2O_2. Dissolves in alcohol and in ether. The solution in water is oxidised by $KMnO_4Aq$ to HClAq and V_2O_5Aq, $2VCl_2$ taking up 3O. Heated in H, is slowly reduced to V; heating to whiteness in NH_3 produces VN (Roscoe, *l.c.*).

Vanadium, ferrocyanide of, *v.* vol. ii. p. 337.

Vanadium, fluorides of. Only one fluoride, VF_3, has been isolated; there are indications of the existence of a higher fluoride in solutions in conc. HFAq.

VANADIUM TRIFLUORIDE $VF_3.3H_2O$. Mol. w. not known; formula probably molecular, from analogy of trihalides of other elements of Group V. Prepared by evaporating a solution of V_2O_3 in HFAq at 100°, and crystallising from water containing a little HFAq. A white crystalline crust, consisting of rhombohedra. Easily soluble in water; solution reacts acid. Insoluble in conc. alcohol. Effloresces in air; loses some water at 100°, and all at 130°, with absorption of O; V_2O_5 is formed on heating to redness in air. An aqueous solution reduces Ag salts to Ag, Hg and Cu salts to mercurous and cuprous salts; alkalis or alkali carbonates ppt. $V_2O_3.xH_2O$ from VF_3Aq (E. Petersen, *J. pr.* [2] 40, 44).

Vanadofluorides. (*Fluovanadites.*) A number of compounds of the forms $VF_3.xM^{I}F$ and $VF_3.xM^{II}F_2$ were obtained by Petersen (*l.c.*) by adding various fluorides to solutions of V_2O_3 in HFAq, and crystallising. These salts are generally greenish coloured, and crystalline; most of them are soluble in water, but not in KFAq; they lose water of crystallisation from 100° to 200°. The vanadofluorides may be regarded as salts of hypothetical acids HVF_4, H_2VF_5, and H_3VF_6; they may also be formulated as double salts (*v. supra*). The following salts are described by Petersen (*l.c.*):

Ammonium vanadofluorides $NH_4VF_4.2aq$, $(NH_4)_2VF_5.aq$, and $(NH_4)_3VF_6$.

Cadmium vanadofluoride $CdVF_5.7aq$ (Piccini a. Giorgis, *G.* 22 [1] 55).

Cobalt vanadofluoride $CoVF_5.7aq$.

Nickel vanadofluoride $NiVF_5.7aq$.

Potassium vanadofluoride $K_2VF_5.aq$

Sodium vanadofluoride $Na_5V_2F_{11}.aq = 2VF_3.5NaF.aq$ (? $Na_2VF_5.aq$).

Zinc vanadofluoride $ZnVF_5.7aq$ (P. a. G., *l.c.*).

Vanadoxyfluorides. (*Fluoxyvanadates.*) These salts are generally produced by dissolving V_2O_5 in HFAq, adding metallic fluorides, and crystallising; also by dissolving V_2O_5 in solutions of metallic fluorides, and crystallising; some of them are obtained by treating solutions of V_2O_5 in metallic fluoride solutions with reducing agents, and then crystallising. The vanadoxyfluorides have been examined by Baker (*C. J.* 33, 388 [1878]), Ditte (*C. R.* 105, 1067; 106, 270 [1888]), Piccini a. Giorgis (*G.* 18, 186 [1889]; *G.* 22 [1] 55 [1892]), and Petersen (*B.* 21, 3257 [1888]; more fully in *J. pr.* [2] 40, 193, 271 [1890]). There are still considerable discrepancies between the results obtained by the different observers. For a criticism of Baker's results *v.* Petersen (*J. pr.* [2] 40, 289–92). The vanadoxyfluorides belong to two main classes: (1) those obtained by dissolving V_2O_5 in HFAq, adding a fluoride (or carbonate), and crystallising: many of these salts are also formed by dissolving V_2O_5 in solutions of fluorides, and crystallising; (2) those obtained by partially reducing solutions of V_2O_5 in HFAq, then adding fluorides, and crystallising. The first class of salts may be divided into (i.) those wherein one atom of O in V_2O_5 is substituted by 2F, and which, therefore, are represented as $xMF.yVO_2F$ (V_2O_5 gives $V_2O_4F_2 = 2VO_2F$); and (ii.) those wherein 3O in V_2O_5 is substituted by 6F, and which, therefore, are represented as $xMF.yVOF_3$ (V_2O_5 gives $V_2O_2F_6 = 2VOF_3$). Salts of the second class are regarded as compounds of MF with VOF_2, and VOF_2 is looked on as obtained by substituting 2O in V_2O_4 by 4F (V_2O_4 gives $V_2O_2F_4 = 2VOF_2$). The salts derived from V_2O_5, *i.e.* $xMF.yVO_2F$ and $xMF.yVOF_3$, are often called *fluoxyvanadates*, and those derived from V_2O_4, *i.e.* $xMF.yVOF_2$, are often called *fluoxyhypovanadates*; the former class of salts will here be called *vanadoxyfluorides*, and the latter *hypovanadoxyfluorides*.

Ammonium vanadoxyfluorides. Three salts are described by Baker (*C. J.* 33, 388 [1878]), and also by Piccini a. Giorgis (*G.* 22 [1] 55, [1892]; the formulæ given by the different experimenters do not agree.

Lamellar ammonium vanadoxyfluoride. This salt was obtained by Baker by dissolving V_2O_5 in NH_4HF_2Aq, and then adding more NH_4HF_2; it separates in small yellow, pearly, hexagonal plates. P. a. G. obtained the salt by dissolving V_2O_5 in a slight excess of HFAq, adding NH_4F in the ratio $3NH_4F:2V_2O_5$, and evaporating. B. gives the formula $6NH_4F.V_2O_5.2VOF_3.2aq$; P. a G. give the formula $3NH_4F.2VO_2F$. If both formulæ are expressed as $3NH_4F.2VO_xF$, then $x = 1\frac{3}{4}$ in Baker's formula and = 2 in the formula of P. a. G. A salt obtained by Petersen (*J. pr.* [2] 40, 193, 271 [1890]), by a similar process to those used by B. and by P. a. G., was formulated by him as $7NH_4F.4VO_2F.HF$.

Pyramidal ammonium vanadoxyfluoride. Obtained by Baker by adding NH_4HF_2 to a solution of the lamellar salt; P. a. G. prepared the salt by dissolving V_2O_5 in excess of HFAq, and exactly neutralising the hot solution by NH_3Aq. This salt crystallises in yellow, simple pyramids (Baker). The formula assigned by B. is $12NH_4F.V_2O_5.2VOF_3$, while that given by P. a. G. is $3NH_4F.VO_2F$; Petersen gives the same formula as P. a. G. If Baker's formula is expressed as $3NH_4F.VO_xF^y$, x must be put $= 1\frac{3}{4}$, and $y = 1\frac{1}{2}$.

Acicular ammonium vanadoxyfluoride. Baker obtained this salt by dissolving the pyramidal salt in warm HFAq and allowing to cool; P. a. G. prepared it by a similar reaction. This salt crystallises in pale-yellow acicular prisms; when dry it has the odour of HF; it acts on glass. The formula given by P. a. G. is $3NH_4F.2VOF_2.aq$; Baker assigned to this salt the formula $3NH_4HF_2.2VOF_3$, but his analyses were, admittedly, not very trustworthy.

Adopting the formulæ given by P. a. G. for the three ammonium vanadoxyfluorides, these salts are represented as

(1) $3NH_4F.2VO_2F = (NH_4)_3V_2O_4F_5$
(2) $3NH_4F.VO_2F = (NH_4)_3VO_2F_4$
(3) $3NH_4F.2VOF_3 = (NH_4)_3V_2O_2F_9$.

A few of the other vanadoxyfluorides seem to belong to one or other of these types; P. a. G. and also Petersen, describe a *potassium vanadoxyfluoride* $3KF.2VO_2F = K_3V_2O_4F_5$, belonging to the same form as the lamellar ammonium salt. But most of the vanadoxyfluorides described belong to forms which are not represented by the ammonium salts. The following are the principal salts:—

Ammonium salts. $9NH_4F.5VOF_3.3HF$; $7NH_4F.4VOF_3.HF$ (Petersen).

Potassium salts $2KF.VO_2F$; $2KF.VOF_3$; $3KF.2VOF_3.HF$; $4KF.VF_5.VOF_3$ (P.).

Sodium salt $3NaF.VOF_3.VO_2F.aq$ (P. a. G.).

Zinc salts. $ZnF_2.VO_2F.7aq$ (P. a. G.); $ZnF_2.ZnO.2VOF_3.14aq$ (B.).

In none of these compounds does the atomic ratio of V to O exceed 1:2. According to Ditte (*C. R.* 105, 1067; 106, 270 [1888]), many compounds of alkali fluorides with V_2O_5 are formed by heating the constituents together, digesting with water, and crystallising; the atomic ratio of V to O in these compounds, as given by Ditte, is 2:5. The formulæ assigned to the compounds may be generalised as $xV_2O_5.yMF$; M = K or Na, $x = 1, 3$, and 4, and $y = 1, 2, 4$, and 8. Ditte (*l.c.*) says that crystals of $V_2O_5.4NH_4F.4aq$ are obtained by dissolving V_2O_5 in hot conc. NH_4FAq, and that this compound is formed, along with $V_2O_5.8NH_4F.4aq$, when V_2O_5 is dissolved in cold conc. NH_4FAq; but the experiments of Baker, Piccini a. Giorgis, and Petersen, all agree in assigning to the compounds formed in these reactions formulæ wherein the atomic ratio of V to O does not exceed 1:2.

Hypovanadoxyfluorides. (*Fluoxyhypovanadates.*) These compounds are formed by partially reducing mixtures of V_2O_5 and fluorides, or carbonates, dissolved in HFAq. If sufficient F is assigned to the metal present to form the normal fluoride, then the atomic ratio of V to the remaining F in these compounds is 1:2, and that of V to O is 1:1; the formulæ are written $xMF.yVOF_2$. All the salts described by Baker and Piccini a. Giorgis, except one, belong to the form $2M^IF.VOF_2$ or $M^{II}F_2.VOF_2$; these formulæ may evidently be written M^I_2(or M^{II})VOF_4.

Ammonium hypovanadoxyfluoride $2NH_4F.VOF_2.aq$ ($= (NH_4)_2VOF_4.aq$) was prepared by Baker (*C. J.* 33, 395) by passing H_2S into a solution of V_2O_5 in HFAq, concentrating, filtering, and adding NH_4F. The same salt was prepared by Piccini a. Giorgis (*G.* 22 [1] 55) by electrolytically reducing a solution of NH_4VO_3 in HFAq, after adding NH_4F; also by reducing NH_4VO_3 in HFAq by SO_2Aq, neutralising by NH_3Aq, and adding NH_4F; and in each case dissolving the crystals that were formed (said by P. a. G. to be $3NH_4F.VOF_2$) in hot HFAq, and crystallising. Petersen (*J. pr.* [2] 40, 196) also obtained this salt. The salt crystallises in clear blue monoclinic forms; $a:b = \cdot9653:1$ (Baker, *l.c.*).

Petersen (*J. pr.* [2] 40, 197) described two other ammonium hypovanadoxyfluorides, $7NH_4F.4VOF_2.5aq$ and $3NH_4F.VOF_2$.

The other hypovanadoxyfluorides described by P. a. G. (*l.c.*) are $2KF.VOF_2$ and $MF_2.VOF_2.2aq$ where M = Cd, Co, Ni and Zn. The K salt was prepared by reducing V_2O_5 in HFAq by SO_2Aq and adding KF; the other salts by dissolving MO, or MCO_3, along with V_2O_5 in HFAq, and reducing electrolytically. According to Petersen (*l.c.* pp. 199, 200), the salts $7KF.3VOF_2$ and $8NaF.3VOF_2.2aq$ also exist.

P. a. G. (*l.c.*) remark that the tendency to form highly fluorinated compounds increases in the family V, Nb, Ta as the atomic weight increases; thus, VO_2F is not affected by a little HFAq, while Nb_2OF forms $NbOF_3$, and $TaOF_3$ is converted into TaF_5. They also point out that the three compounds, $ZnF_2.VO_2F.7aq$, $ZnF_2.VOF_2.7aq$, and $ZnF_2.VF_3.7aq$, all crystallise with the same number of molecules of water, all contain the same number of atoms, have the same crystalline form, and are geometrically isomorphous.

VANADIUM PENTAFLUORIDE VF_5. According to Petersen (*J. pr.* [2] 40, 271), this compound exists in a solution of V_2O_5 in conc. HFAq. No compound was isolated, nor is any trustworthy evidence given of the existence of VF_5 in solution.

Vanadium, haloid compounds of. When V is heated in excess of Cl the tetrachloride VCl_4 is produced; heating in Br produces the tribromide VBr_3. V does not combine with I. The haloid compounds of V belong to the forms VX_4, VX_3, and VX_2; X = Cl in each case, X = Br or F in the one case of VX_3. The formula VX_4 is molecular; the other formulæ are probably molecular. VCl_4, $BiCl_3$, AsI_3, and PI_3 are the only dihalides known of members of Group V. Attempts to prepare halides higher than VX_4 have failed. Solutions in water of the haloid compounds of V behave like solutions of the corresponding oxides in haloid acids; VCl_4Aq like a solution of V_2O_4 in HClAq, VX_3Aq like a solution of V_2O_3 in HXAq, and VCl_2Aq like a solution of V_2O_2 in HClAq. VCl_4 is decomposed by heat to VCl_3 and Cl, and heating VCl_3 with H produces VCl_2. VF_3 combines with metallic fluorides to form *vanadofluorides*, many of which belong to the form $M^I_2VF_5$ or $M^{II}VF_5$ (*v.* p. 844). Several oxychlorides and oxybromides of V have been isolated: VOX_3 and VOX_2, where X = Cl or Br; also VOCl, V_2O_2Cl, and VO_2Cl; the existence of other oxybromides also is probable. No oxyfluoride has been isolated with certainty. But many compounds exist which may be regarded as containing the oxyfluorides VO_2F, VOF_3, and VOF_2 respectively; the compounds $VO_2F.xMF$ and $VOF_3.xMF$ are obtained by dissolving V_2O_5 and fluorides in HFAq and crystallising; they are described as *vanadoxyfluorides* (p. 844); the compounds $VOF_2.xMF$ are obtained by partially reducing solutions of V_2O_5 and fluorides in HFAq, they are described as *hypovanadoxyfluorides* (p. 845).

Vanadium, iodides of. No iodide of V has been isolated. No reaction occurs when vapour of I is passed over VN heated to redness, nor do I and V_2O_3 react at any temperature (Roscoe, *C. J.* [2] 9, 28). I does not react with V_2O_5 when digested therewith for a long time in presence of water or alcohol (Guyard, *Bl.* [2] 25, 351).

Vanadium, nitrides of. V and N combine directly. Two nitrides are known.

VANADIUM MONONITRIDE VN. Mol. w. not known. Obtained by heating V in a stream of pure N; also by saturating $VOCl_3$ with dry NH_3, and heating to full whiteness in a stream of NH_3. Better prepared by heating NH_4VO_3 in the air, and then heating the residue to a full white heat in a stream of dry NH_3 (Roscoe, *C. J.* [2] 8, 344). VN may also be prepared by heating V_2O_3 to whiteness in NH_3 (R., *l.c.*). VN is a greyish-brown, metal-like powder; heated in air it is oxidised to V_2O_4 and then to V_2O_5; heated with soda-lime it gives off NH_3.

VANADIUM DINITRIDE VN_2. A black powder; exposed to air gives off NH_3 and is oxidised. Prepared by saturating $VOCl_3$ with dry NH_3, heating the solid so obtained in a glass tube as long as NH_4Cl sublimes, washing the residue with water containing a little NH_3, and drying *in vacuo* over H_2SO_4 (Roscoe, *C. J.* [2] 6, 349); examined by Uhrlaub, who did not succeed in determining its composition (*P.* 103, 134; *cf.* Schafarik, *W. A. B.* 33, 5).

Vanadium, oxides and hydrated oxides of. By gently heating V in air the oxide V_2O is possibly formed, and, on continued heating, oxidation proceeds to V_2O_2, V_2O_3, V_2O_4, and finally V_2O_5. The oxides V_2O_4, V_2O_3, and V_2O_2 are also formed by reducing V_2O_5 by heating with H or K. Several oxides intermediate between V_2O_4 and V_2O_5 seem also to exist. The oxides V_2O_2, V_2O_3, V_2O_4, and V_2O_5 are feebly basic; V_2O_4 and V_2O_5 are also acidic. The oxides of V correspond in composition with the oxides of N; corresponding oxides of Bi are known. The names generally given to the oxides of V do not, unfortunately, tally with the names given to the corresponding oxides of N; thus, V_2O_2 is generally called hypovanadous oxide, while NO is called nitric oxide; V_2O_5 is called vanadic oxide, while the name nitrogen peroxide is often quite wrongly applied to NO_2. The mol. w. of none of the oxides of V is known.

? VANADIUM MONOXIDE (? V_2O). 'When the powdered metal is . . . slowly heated in a current of air it glows brightly, with absorption of oxygen, forming in the first place a brown oxide (V_2O or V_2O_2); and on further heating this oxide again glows, and passes through the black trioxide and blue tetroxide to pentoxide' (Roscoe, *C. J.* [2] 8, 357). This statement seems to contain all that is known of an oxide lower than V_2O_2.

VANADIUM DIOXIDE V_2O_2. (*Hypovanadous oxide.*) This substance was supposed by Berzelius (*P.* 22, 1) to be V; Roscoe (*T.* 1868. 1) proved it to be an oxide with the atomic ratio V:O = 1:1. The mol. w. is not known; the formula is generally written V_2O_2 rather than VO, as the double formula is, on the whole, more in keeping with the reactions of the compound.

Formation.—1. By heating one of the higher oxides with K (Berzelius, *l.c.*).—2. By passing vapour of $VOCl_3$, mixed with much dry H, over red-hot charcoal (Schafarik, *A.* 109, 85).—3. By strongly heating V_2O_3 and V_2O_5, mixed in the ratio V_2O_3:V_2O_5, out of contact with air (Petersen, *J. pr.* [2] 40, 193).

Preparation.—A mixture of much dry H and vapour of $VOCl_3$ (*q. v.* p. 854) is passed through a hard glass tube containing powdered charcoal and kept red hot. Some solid oxychlorides are deposited on the cooler parts of the tube, while the V_2O_2 remains mixed with the C. The contents of the tube are then strongly heated in a current of dry H to remove traces of Cl compounds; and the grey metal-like V_2O_2 is separated from the C (Roscoe, *C. J.* [2] 6, 334). When Zn, Cd, or Na-amalgam is added to a solution of V_2O_5 in H_2SO_4Aq (prepared by dissolving the oxide in hot conc. acid and diluting with 50 pts. water), the liquid becomes blue, green, and finally lavender. The lavender solution absorbs O very rapidly; exposure to the air for a few seconds causes the colour to change to deep chocolate-brown. By determining the quantity of standardised $KMnO_4Aq$ decolourised by the lavender solution, Roscoe (*C. J.* [2] 6, 334) proved that this solution contained V_2O_2, probably combined with SO_3. After passing air into the lavender solution until it becomes permanently blue, the solution contains V_2O_4; if the free acid in the lavender solution is neutralised by zinc, and the liquid is then exposed to the air until permanently brown, and a little acid is then added, a green solution is formed which contains V_2O_3 (R., *l.c.*).

Properties and Reactions.—A light-grey, lustrous powder; or a lustrous, metal-like, crystalline crust, S.G. 3·64; very brittle; fuses at a very high temperature. Heated to redness in air, V_2O_2 burns to V_2O_3; heated in O, burns to V_2O_5. Insoluble in water; dissolves in dilute acids, giving a lavender solution, which bleaches strongly; from these solutions KOHAq or

NH_3Aq ppts. a brown hydrated oxide, which rapidly oxidises (Brierley, *C. J.* 49, 824). According to Petersen (*J. pr.* [2] 40, 194), V_2O_2 dissolves in HFAq, and on evaporation, solution of the residue in water, and evaporation over H_2SO_4, blue, microscopic crystals are obtained, which are, perhaps, $VOF_2.x$aq; no analyses were made. Addition of alkali fluorides to V_2O_2 in HFAq produces various compounds of the form $xVOF_2.yMF$ (*v.* HYPOVANADOXYFLUORIDES, p. 845).

HYDRATE OF VANADIUM DIOXIDE. By adding NH_3Aq to a lavender-coloured solution of V_2O_2 (? in H_2SO_4Aq), Brierley (*C. J.* 49, 824) obtained a deep-purple gelatinous pp. which he said was hydrated V_2O_2; the pp. rapidly oxidised in the air.

VANADIUM TRIOXIDE V_2O_3. (*Vanadous oxide. Vanadium sesquioxide.*) Mol. w. not known. This compound was represented by Berzelius as VO (V = 68·5, O = 8).

Formation.—1. By heating V_2O_5 to redness in H (Schafarik, *A.* 109, 85). The presence of traces of P_2O_5 prevents reduction (Roscoe, *C. J.* [2] 6, 331).—2. By heating V_2O_5 in a carbon crucible (Berzelius, *P.* 22, 1).

Preparation.—Pure V_2O_5 is heated in perfectly pure and dry H until the substance ceases to lose weight; the tube is allowed to cool completely in H, and then a stream of dry air is passed through it (Roscoe, *C. J.* [2] 6, 331). When a solution of V_2O_5 in conc. H_2SO_4 is much diluted, and then treated with Mg until the liquid is green, this solution contains V_2O_3, combined with SO_3 (*v.* VANADOUS SALTS, *infra*). A similar solution is obtained from the lavender solution of V_2O_2 in H_2SO_4Aq (prepared from V_2O_5 in H_2SO_4, *v. supra*) by neutralising free acid by zinc, exposing to the air, and adding a little acid (Roscoe, *C. J.* [2] 6, 337).

Properties and Reactions.—V_2O_3 is a black powder, resembling graphite; or, formed by reducing $VOCl_3$ by H, it is a black, lustrous, crys-alline crust. S.G. 4·72 at 16°. Does not fuse n the blowpipe flame. When warm V_2O_3 is exposed to the air it glows and oxidises to V_2O_5; nd even at the ordinary temperature it takes up , being changed after some months to V_2O_4 (R., c.). Heated in Cl gives V_2O_5 and $VOCl_3$ (R., *l.c.*). Heated in NO_2 to 300°–400° V_2O_3 is oxidised to V_2O_5 (Sabatier a. Senderens, *C. R.* 115, 236). Heating to redness in H_2S produces V_2S_3 (Kay, *C. J.* 37, 728). V_2O_3 dissolves in hot conc. H_2SO_4, forming $V_2O_3.xSO_3$ (*v.* VANADOUS SALTS, *infra*). V_2O_3 dissolves in HFAq, and $VF_3.3H_2O$ has been isolated from this solution (*v.* VANADIUM TRIFLUORIDE, p. 844).

HYDRATE OF VANADIUM TRIOXIDE. By adding KOHAq, or NH_3Aq, to an aqueous solution of $V_2O_3.4SO_3.9H_2O$ (*v. infra*) Brierley (*C. J.* 49, 824), obtained a dirty green, gelatinous pp., which oxidised rapidly in air. According to B., this pp. was hydrated V_2O_3.

VANADOUS SALTS $V_2O_3.xX$ (X = acidic oxide) or $V_2R_3^{II}$ (R^{II} = acidic radicle). Only one salt derived from an oxyacid has been certainly isolated; it has the composition $V_2O_3.4SO_3.xH_2O$, or the formula may be written $V_2H_2(SO_4)_4.yH_2O$.

Vanadous tetrasulphate, or *acid vanadous sulphate*, $V_2O_3.4SO_3.xH_2O$ or $V_2H_2(SO_4)_4.yH_2O$.

A hydrate with $x = 3$ or $y = 2$ was obtained by Gerland (*B.* 10, 2111 [1877]) by heating a solution of V_2O_4 in a large excess of conc. H_2SO_4 for a long time at 120°, and treating the blue crystalline crust thus formed (consisting chiefly of $V_2O_4.3SO_3.x$aq, *v.* HYPOVANADIC SALTS, p. 848) with boiling water, when $V_2O_3.4SO_3.3H_2O$ remained. G. supposed that reduction of V_2O_4 was effected by dust in the air.

Brierley (*C. J.* 49, 822 [1886]) prepared $V_2O_3.4SO_3.9H_2O(=V_2H_2(SO_4)_4.8H_2O)$ by electrolysing a solution of V_2O_4 in H_2SO_4. The solution was prepared by reducing V_2O_5 in conc. H_2SO_4, after dilution, by SO_2. The deep-blue solution was placed in a Pt dish which formed the negative electrode, and a porous pot containing dilute H_2SO_4Aq was arranged so that it just touched the surface of the liquid in the Pt dish; a plate of Pt immersed in the H_2SO_4Aq formed the positive electrode. The Pt dish was warmed during the process, so that electrolysis and evaporation proceeded together. Electrolysis was continued until the liquid was deep green, and a drop placed in a little water showed no trace of blue colour. Conc. H_2SO_4, equal to twice the bulk of the green liquid, was added; after 24 hours the green, sandy pp. was collected, washed with conc. alcohol, and dried over H_2SO_4 in coal-gas. The salt dissolved in water, and alkali ppd. from this solution a dirty-green gelatinous substance, said by B. to be $V_2O_3.xH_2O$. This pp. dissolved in an aqueous solution of $V_2O_3.4SO_3.9H_2O$, forming a chocolate-brown solution, giving a lustrous green solid on evaporation, which dissolved in water to form a brown solution. B. concluded that the brown solution contained a compound of V_2O_3 and SO_3 more basic than $V_2O_3.4SO_3$.

Gerland (*B.* 11, 106 [1878]) mentions the *normal vanadous sulphate* $V_2(SO_4)_3(=V_2O_3.3SO_3)$ as if he had prepared it; no details are given.

VANADIUM TETROXIDE V_2O_4. (*Hypovanadic oxide.*) Mol. w. not known. Represented by Berzelius as VO_2(V = 68·5, O = 8).

Formation.—1. By allowing V_2O_3 to absorb O from the air (*cf.* HYPOVANADO-VANADIC OXIDES, p. 851).—2. By strongly heating a mixture of 5 pts. V_2O_3 and 6 pts. V_2O_5, in absence of air.—3. By the electrolysis of molten V_2O_5 (Buff a. Wöhler, *A.* 110, 277).—4. By heating $V_2O_4Cl_2.5$aq in a stream of CO_2 (Crow, *C. J.* [2] 15, 453).

Preparation.—A solution of V_2O_4 in H_2SO_4, obtained by reducing V_2O_5 in conc. H_2SO_4 by SO_2, is ppd. by Na_2CO_3Aq, and the pp. is washed and dried by heating *in vacuo* (Berzelius, *P.* 22, 1).—2. V_2O_3 is exposed to the air for some months, until the colour has changed to blue (Roscoe, *C. J.* [2] 6, 338).—3. V_2O_5 is dissolved in hot conc. HClAq; when Cl ceases to be given off the liquid is saturated with H_2S, filtered from S, evaporated to dryness at 100° and the $V_2O_4Cl_2.x$aq thus formed is heated to redness in a stream of dry CO_2 (Crow, *l.c.* pp. 457, 458).

Properties and Reactions.—A blue, lustrous, crystalline powder; prepared by heating $V_2O_4Cl_2$ in CO_2 it forms a dark-green, amorphous powder (Crow, *l.c.*). Infusible at a high temperature. Insoluble in water. When kept in a loosely-stoppered bottle V_2O_4 gradually absorbs O, forming V_2O_5 (Crow, *l.c.*). Dissolves easily in acids, forming bright-blue liquids; the same solutions are obtained by the action of moderate reducers, such as SO_2Aq, H_2SAq, or $H_2C_2O_4Aq$, on solutions of V_2O_3 in acids, also by passing air into V_2O_2 in H_2SO_4Aq until the liquid becomes permanently blue (Roscoe, *l.c.*; *v. infra*, Hypovanadic salts). Petersen (*J. pr.* [2] 40, 194) supposed that the blue microscopic crystals he obtained by dissolving V_2O_4 in excess of HFAq and evaporating were $VOF_2.x$aq, but he did not obtain enough to make an analysis. V_2O_4 dissolves readily in alkali solutions, forming *hypovanadates*, $M_2V_4O_9$ (*q.v.* under Vanadium oxyacids, and salts and derivatives thereof, p. 853).

Hydrates of hypovanadic oxide. By adding Na_2CO_3Aq, drop by drop, to a solution of V_2O_4 in HClAq or H_2SO_4Aq, till the supernatant liquid was colourless, filtering rapidly in CO_2, and drying on a porous tile over H_2SO_4 *in vacuo*, Crow (*l.c.*) obtained the black, amorphous *heptahydrate* $V_2O_4.7$aq; and on heating this in CO_2 for some hours at 100° he obtained the *trihydrate* $V_2O_4.3$aq.

HYPOVANADIC (or *vanadyl*) SALTS $V_2O_4.xX$ (X = acidic oxide). Only a few compounds of V_2O_4 with acidic oxides have been isolated. The sulphates have been studied more than any other salts; they are most simply represented as $V_2O_4.xSO_3.yH_2O$. The compound $V_2O_4.2SO_3$ may be called the normal sulphate; the formula may be expressed as $V_2O_2.(SO_4)_2$ or $VO.SO_4$. The compound $V_2O_4.3SO_3.6H_2O$ may be called acid sulphate; the formula may be expressed as $V_2O_2.SO_4(SO_4H)_2.5H_2O$ or $(V_2O_2)H_2(SO_4)_3.5H_2O$, or $(VO.SO_4)_2.H_2SO_4.5H_2O$, or it may be written $V_2O_4.2SO_3.H_2SO_4.5H_2O$. When the formulæ of the compounds of V_2O_4 with acidic oxides are written $V_2O_4.X$ the compounds are generally called *hypovanadic salts*; when the formulæ are written $V_2O_2.xR$ (R = acidic radicle) the name *divanadyl salts* is usually given to the compounds; and when these compounds are regarded as $VO.xR$, it is customary to call them *vanadyl salts*. Hypovanadic sulphates are obtained (1) by dissolving V_2O_4 in hot conc. H_2SO_4 and boiling; (2) by dissolving V_2O_5 in conc. H_2SO_4, reducing by SO_2 or $H_2C_2O_4$, and evaporating; (3) by dissolving V_2O_5 in conc. H_2SO_4 and boiling in the air for some time. In reaction (3) $V_2O_5.xSO_3$ seems to be formed and then partially reduced, by dust or products of combustion of coal-gas, to $V_2O_4.xSO_3$; the products are mixtures of $V_2O_5.xSO_3$ and $V_2O_4.xSO_3$ (Gerland, *B.* 11, 98).

Hypovanadic disulphate, or *normal divanadyl sulphate*, $V_2O_4.2SO_3$ or $V_2O_2.(SO_4)_2$. (*Vanadyl sulphate* $VO.SO_4$.) Prepared by Gerland (*B.* 10, 2109 [1877]; supplementing *B.* 9, 869) by dissolving V_2O_4 in a large excess of conc. H_2SO_4 and heating to the boiling-point of the liquid for a long time. The salt separated as a green-blue powder; insoluble in water, cold or hot; insoluble HClAq and H_2SO_4. (G. does not say how the salt was obtained pure for analysis; no analyses are given of the salt prepared exactly as described above.) Various *hydrates* are described by G. obtained by different processes. Crow (*C. J.* [2] 15, 456 [1876]), obtained the *heptahydrate* by repeatedly treating hexahydrated trisulphate (*v. infra*) with absolute alcohol.

Hypovanadic trisulphate, or *acid divanadyl sulphate*, $V_2O_4.3SO_3.xH_2O$ or $(V_2O_2)H_2(SO_4)_3.yH_2O$ [$y = x - 1$]. (*Acid vanadyl sulphate* $(VO.SO_4)_2.H_2SO_4.yH_2O$.) Hydrates with $x = 4$ and 3 (or $y = 3$ and 2) were prepared by Gerland (*B.* 10 2, 109); and a hydrate with $x = 6$ (or $y = 5$) by Crow (*C. J.* [2] 15. 455).

By dissolving V_2O_4 in a large excess of conc. H_2SO_4, heating for a long time at c. 120°, and drying the small, blue, transparent crystals that formed on a porous tile over H_2SO_4, Gerland obtained a substance which gave analytical results approaching those required by the formula $V_2O_4.3SO_3.4H_2O$. The salt was not obtained quite free from admixed $V_2O_5.4SO_3.xH_2O$. This *tetrahydrate* was partially decomposed by cold water, giving lustrous scales which, after washing with alcohol and ether and drying over H_2SO_4, had the composition of a *trihydrate*, $V_2O_4.3SO_3.3H_2O$.

Crow obtained a *hexahydrate* $V_2O_4.3SO_3.6H_2O$, by reducing by SO_2 a solution of V_2O_5 in conc. H_2SO_4, heating at 100° for some time, drying the light-blue crystals that separated on a tile, removing acid by washing with ether, and drying by pressure between paper. The crystals deliquesced in air to a blue syrup; they were insoluble in ether, and scarcely soluble in absolute alcohol.

The formulæ of the various hydrated hypovanadic sulphates are as follows:—

Hypovanadic sulphates; or	*Divanadyl sulphates*; or	*Vanadyl sulphates.*
$V_2O_4.2SO_3$	$V_2O_2.(SO_4)_2$	$VO.SO_4$ (Gerland).
$V_2O_4.2SO_3.3H_2O$	$V_2O_2.(SO_4)_2.3H_2O$	$2(VO.SO_4).3H_2O$ (G.)
$V_2O_4.2SO_3.4H_2O$	$V_2O_2.(SO_4)_2.4H_2O$	$VO.SO_4.2H_2O$ (Crow, confirming Berzelius).
$V_2O_4.2SO_3.7H_2O$	$V_2O_2.(SO_4)_2.7H_2O$	$2(VO.SO_4).7H_2O$ (G., also C.)
$V_2O_4.2SO_3.10H_2O$	$V_2O_2.(SO_4)_2.10H_2O$	$VO.SO_4.5H_2O$ (G.)
$V_2O_4.2SO_3.13H_2O$	$V_2O_2.(SO_4)_2.13H_2O$	$2(VO.SO_4).13H_2O$ (G.)
$V_2O_4.3SO_3.3H_2O$	$(V_2O_2)H_2(SO_4)_3.2H_2O$	$2(VO.SO_4).H_2SO_4.2H_2O$ (G.)
$V_2O_4.3SO_3.4H_2O$	$(V_2O_2)H_2(SO_4)_3.3H_2O$	$2(VO.SO_4).H_2SO_4.3H_2O$ (G.)
$V_2O_4.3SO_3.6H_2O$	$(V_2O_2)H_2(SO_4)_3.5H_2O$	$2(VO.SO_4).H_2SO_4.5H_2O$ (C.)

Bevan (*C. N.* 38, 294) obtained *divanadyl dithionate* by adding BaS_2O_6Aq to $V_2O_2(SO_4)_2Aq$, filtering, and evaporating *in vacuo*: the salt was not obtained pure. By dissolving V_2O_4 in HNO_3Aq Berzelius (*P.* 22, 1) obtained a blue liquid which probably contained *hypovanadic nitrate*; but no solid could be isolated, as on evaporation to dryness decomposition occurred, with formation of V_2O_5. V_2O_4 also dissolves in H_3PO_4Aq; on evaporation at 50° blue crystals are obtained, which deliquesce to a blue syrup; these crystals are probably *hypovanadic phosphate*, but no analyses are given (B., *l.c.*). Berzelius obtained what were probably compounds of V_2O_4 with As_2O_5, B_2O_3, CrO_3, MoO_3, and a few other acidic oxides (cf. *Lehrbuch* [5th ed.] 3, 1053).

Vanadium pentoxide V_2O_5. (*Vanadic oxide. Vanadic anhydride.*) Mol. w. not known. Represented by Berzelius as VO_3 (V = 68·5, O = 8).

Formation.—1. By strongly heating any of the lower oxides in air or O.—2. By heating $NH_4.VO_3$ in air to dull redness.—3. By decomposing $VOCl_3$ by water.—4. By heating $V_2O_3.4SO_3.9aq$ to bright redness (Brierley, *C. J.* 49, 824).

Preparation.—Pure $VOCl_3$ is decomposed by water, and the ppd. V_2O_5 is washed till the washings are free from acid (HClAq is produced) and heated until dry (Schafarik, *J. pr.* 76, 142). For the preparation of V_2O_5 from *vanadinite* and other sources of V compounds, *v.* Vanadium, *Preparation* of (p. 841).

Properties.—A pale-yellow powder, with a reddish tinge. When heated to full redness out of contact with any reducing agents, V_2O_5 melts, and solidifies on cooling to a mass of yellow-red, crystalline needles, appearing ruby-red by transmitted light; should the V_2O_5 used contain V_2O_4, which is often the case when the V_2O_5 is prepared by heating $NH_4.VO_3$, the solid obtained by fusion and cooling appears violet to nearly black, and does not seem to be crystalline (Berzelius, *P.* 22, 1). As molten V_2O_5 cools nearly to its solidifying-point much heat is given out, and the mass glows until solidification is complete (B., *l.c.*). V_2O_5 is said not to be changed at a white heat, provided no trace of a reducing agent is present (B., *l.c.*); but according to Read (*C. J.* 65, 313 [1894]) molten V_2O_5 gives off O, producing V_2O_3, which on cooling in air takes up O, forming steel-blue crystals of V_2O_4. The crystals of V_2O_5 are rhombic (*v.* Nordenskjold, *P.* 112, 160). S.G. (crystalline) 3·5 at 20° (Schafarik, *J. pr.* 76, 142). V_2O_5 is odourless and tasteless; it reddens moist litmus paper; 1,000 pts. boiling water dissolve scarcely 1 pt. V_2O_5 (B., *l.c.*). With molten alkalis or alkali carbonates V_2O_5 produces *vanadates* (*q.v.* p. 851). V_2O_5 dissolves in conc. H_2SO_4, HClAq, HNO_3Aq, or HFAq (*cf.* Vanadic salts, p. 850).

According to Ditte (*C. R.* 101, 698), V_2O_5 exists in three forms: (1) *red*, obtained by heating $NH_4.VO_3$ in a closed crucible, treating with HNO_3 and repeatedly heating to redness; (2) *yellow*, obtained by heating $NH_4.VO_3$ to 440° in a stream of air; and (3) *crystalline*, obtained by treating the yellow form with HNO_3, and then fusing. D. says that the red form is somewhat soluble in water, 1,000 c.c. dissolving 8 g. at 20°; that the yellow form is very slightly soluble, and the crystalline form is insoluble, in water. He also says that the red form absorbs water from the air, producing hydrates with $2H_2O$ and $5H_2O$; and that addition of NHCl, KCl (and other salts) to an aqueous solution of the red variety causes ppn. of a hydrate of the yellow form of V_2O_5, which hydrate, when dry, is a dark-red powder having the composition $V_2O_5.2H_2O$ (= $H_4V_2O_7$) and is almost insoluble in water. (No analyses are given by D.)

Reactions.—1. When *heated* and kept molten, V_2O_3 is formed, and this absorbs O as it cools in air and forms V_2O_4 (Read, *C. J.* 65, 313 [1894]). 2. Heated to redness in *hydrogen* till it ceases to lose weight, V_2O_5 is reduced to V_2O_3 (Schafarik, *A.* 109, 85); traces of P_2O_5 prevent the reduction (Roscoe, *C. J.* [2] 6, 331).—3. Heating with *potassium* produces V_2O_3 (Berzelius, *P.* 22, 1).—4. V_2O_3 is produced by heating V_2O_5 in a *carbon* crucible (B., *l.c.*). For action of Mg, Zn, &c. on solutions of V_2O_5, *v.* Vanadic salts, (p. 850).—5. When mixed with *carbon and heated in chlorine*, V_2O_5 yields $VOCl_3$ (Roscoe, *C. J.* [2] 6, 342).—6. Electrolysis of molten V_2O_5 produces V_2O_4 (Buff a. Wöhler, *A.* 110, 277).—7. According to Ditte (*C. R.* 103, 55), *fusion with potassium cyanide* produces V_2O_3 (N, K_2O, and CO_2 being also formed). Carnot (*C. R.* 104, 1803, 1850; 105, 119) says that a *boiling solution of potassium cyanide* produces KVO_3 (CO_2 and N being given off); and that by dropping V_2O_5 into excess of boiling KCNAq there is formed $K_2V_4O_9$ (with evolution of N and CO_2). No analyses are given either by D. or C.—8. Ditte (*C. R.* 103, 55) asserts that the products of the interaction of V_2O_5 and *potassium iodide or bromide* are $K_2V_4O_9$, KVO_3, and I or Br. The reactions are said to occur between V_2O_5 and molten KI or KBr; and KIAq is said to react in the same way as the molten salt.—9. When V_2O_5 is heated with molten *boron trioxide*, a pale-yellow glass is formed, which is said by Guyard (*Bl.* [2] 40, 354) to be a vanadic borate; no analyses, composition, or methods of purification are given.—10. V_2O_5 dissolves in *hot conc. sulphuric acid*, forming $V_2O_5.xSO_3$, generally along with more or less $V_2O_4.xSO_3$ (*v.* Vanadic salts, p. 850).—11. V_2O_5 dissolves in *conc. hydrochloric acid*; Cl is given off on heating; after the passage of H_2S followed by evaporation at 100° the oxychloride $VO_2Cl.xaq$ is obtained (Crow, *C. J.* 30, 457; *cf.* Vanadium dioxymonochloride, p. 854).—12. By dissolving V_2O_5 in *conc. hydrochloric acid in presence of platinic chloride*, Brauner (*M.* 3, 58) obtained large tablets having the composition $2(VOCl_2.PtCl_4).21aq$.—13. An oxyiodide $2VOI_2.9aq$ is obtained, according to Ditte (*C. R.* 102, 1310), by adding excess of *hydriodic acid* to a warm aqueous solution of red V_2O_5, removing free I by shaking with silver powder, filtering, and evaporating *in vacuo*. (No analyses are given.)—14. V_2O_5 dissolves in *hydrofluoric acid*, forming a pale-yellow solution, the colour of which becomes deeper on dilution (Piccini a. Giorgis, *G.* 22 [1] 55). Petersen (*J. pr.* [2] 40, 271) supposed that a solution in conc. HFAq contained VF_5; but he did not separate this compound, nor does he give any direct evidence in favour of its existence beyond the preparation from the solution of V_2O_5 in HFAq of a compound which may be represented as $2KF.VF_5.VOF_3$, and other compounds of the forms $xMF.yVOF_3$ and $xMF.yVO_2F$. By adding metallic fluorides to solutions of V_2O_5 in HFAq, and crystallising, vanadoxyfluorides are formed; these compounds are of the forms $xMF.yVOF_3$ and $xMF.yVO_2F$ (*v.* Vanadoxyfluorides, p. 844).—15. Vanadoxyfluorides are also formed by dissolving V_2O_5 in *alkali fluoride solutions*, and crystallising (*cf. infra, Combinations*, No. 5).—16. If a *solution of V_2O_5 in hydrofluoric acid is partially reduced*, and then evaporated with metallic fluorides, *hypovanadoxyfluorides* (*q. v.* p. 845) are formed; these salts are of the form $xMF.yVOF_2$.—17. By boiling V_2O_5 with *hydrogen peroxide* solution, a black liquid was obtained that deposited a black-brown crust of indefinite composition (Cammerer, *Chem. Zeit.* 19, 957).—18. By fusion with *alkali* or *alkali carbonates* vanadates are formed (*v.* Vanadates, p. 851).

Combinations.—1. With *water*, but not directly, to form $V_2O_5.H_2O$ and $V_2O_5.2H_2O$ (*v. Metavanadic acid* and *Pyrovanadic acid*, under Vanadium oxyacids, and salts and derivatives thereof, p. 851).—2. With various *acidic oxides*: (1) With SO_3 to form $V_2O_5.xSO_3$, formed by dissolving V_2O_5 in hot conc. H_2SO_4; (2) with As_2O_5 to form $V_2O_5.xAs_2O_5$; (3) with P_2O_5 to form $V_2O_5.xP_2O_5$; (4) with I_2O_5 to form $V_2O_5.xI_2O_5$; (5) with MoO_3 to form $V_2O_5.xMoO_3$; (6) with WO_3 to form $V_2O_5.xWO_3$; (7) with P_2O_5 and SiO_2 to form $V_2O_5.xP_2O_5.ySiO_2$. Most of these compounds combine with the stronger bases M_2O and MO to form salt-like compounds. The compounds of V_2O_5 with SO_3 are described as *vanadic sulphates* under Vanadic salts (*infra*); the compounds with other acidic oxides are described respectively as *arseno-vanadic acids and salts*, *iodo-vanadic acids*, *molybdo-vanadic acids and salts*, *phospho-vanadic acids and salts*, *phospho-silico-vanadic acid*, and *tungsto-vanadic acids and salts*, under Vanadium oxyacids, and salts and derivatives thereof (*v.* pp. 853–4).—3. With *vanadium tetroxide* to form oxides intermediate between V_2O_4 and V_2O_5 (*v.* Hypovanado-vanadic oxides, p. 851).—4. With *vanadium trioxide* to form V_2O_4; produced by heating equivalent weights of the two oxides out of contact with air (Berzelius, *P.* 22, 1; Petersen, *J. pr.* [2] 40, 193).—5. With *alkali fluorides*. According to Ditte (*C. R.* 105, 1067; 106, 270), several compounds of the form $xV_2O_5.yMF$ are formed by fusing V_2O_5 with alkali fluorides, extracting with water, and crystallising; D. gives formulæ where $x=1$, 3 and 4, $y=1$, 2, 4 and 8, and $M=K$ and Na; but he does not give analyses of the salts (*v.* Vanadoxyfluorides, p. 844).

Hydrates of vanadic oxide. The hydrates $V_2O_5.H_2O=HVO_3$ and $V_2O_5.2H_2O=H_4V_2O_7$ have been isolated; these compounds are acids (*v.* Vanadic acids, p. 851). Ditte (*C. R.* 101, 698) asserts, without giving analyses, that a pentahydrate $V_2O_5.5H_2O$ is formed by absorption of water from the air by the red form of V_2O_5 (*v.* Vanadium pentoxide, *Properties*, p. 849).

VANADIC SALTS $V_2O_5.xX$ ($X=$ acidic oxide). A few compounds of this form have been isolated. The sulphates have been better studied than the other salts. Two sulphates, $V_2O_5.2SO_3.xH_2O$ and $V_2O_5.3SO_3.xH_2O$, have been isolated. If x is taken to be 2 in the first salt and 3 in the second, then the formulæ may be written as $(VO_2)_2SO_4.H_2SO_4.H_2O$ and $(VO_2)_2SO_4.2H_2SO_4.H_2O$ respectively: [$(VO_2)_2SO_4.H_2SO_4.H_2O=V_2O_5.2SO_3.2H_2O$; $(VO_2)_2SO_4.2H_2SO_4.H_2O=V_2O_5.3SO_3.3H_2O$]. If the salts are anhydrous, as seems most probable from the analyses, then the formulæ may be written $(VO_2)_2SO_4.SO_3$ and $(VO_2)_2SO_4.2SO_3$ respectively. Neither of the salts can be regarded as the normal salt. The sulphates are obtained by dissolving V_2O_5 in hot conc. H_2SO_4.

Vanadic disulphate $V_2O_5.2SO_3(?\,xH_2O)$. **Prepared by Berzelius (*P.* 22, 39); examined also by Fritsche (*J. pr.* 53, 93), Gerland (*B.* 11,** 98), and Münzig (*C. C.* 1889 (ii.) 908). The salt seems to be without water of crystallisation; F. (*l.c.*) says it crystallises with H_2O. V_2O_5 is dissolved in hot conc. H_2SO_4, and the solution is boiled for a considerable time, when small crystals separate, some of which are brown and some ruby-red, lustrous, and transparent. The crystals are heated in a bath of molten lead until SO_3 ceases to be given off (G., *l.c.*). According to Münzig (*l.c.*), the orange-coloured crystalline powder that separates when V_2O_5 is added to boiling conc. H_2SO_4 until the acid is saturated is $V_2O_5.2SO_3$. By keeping a solution of V_2O_5 in a large excess of conc. H_2SO_4 at 130°–150° for a long time, Gerland (*l.c.*) obtained a hard, opaque, sealing-wax red, crystalline crust composed of V_2O_5 and SO_3 in approximately the ratio $V_2O_5:2SO_3$.

$V_2O_5.2SO_3$ [$=(VO_2)_2SO_4.SO_3$] is described by G. (*l.c.*) as a clear red, crystalline, deliquescent solid; addition of a drop or two of water ppts. $V_2O_5.xH_2O$.

Vanadic trisulphate $V_2O_3.3SO_3(?\,xH_2O)$. This salt seems to have been obtained by Berzelius (*l.c.*). Ditte (*C. R.* 102, 757) gave x the value 3; Gerland's analyses (*l.c.*) were inconclusive, the percentage of water found varying from ·8 to 7·3. G. (*l.c.*) prepared this salt by long-continued boiling of a solution of V_2O_5 in a large excess of conc. H_2SO_4; small crystals separated, some of them brown and some ruby-red and transparent (probably regular octahedra). When the boiling was not continued for so long a time, G. noticed that fine, golden-yellow, lustrous needles separated. The composition of the crystals in each case was very nearly that required by the formula $V_2O_5.3SO_3$. More or less $V_2O_4.2SO_3$ was always formed; G. found that addition of a little $HClO_4$ prevented the formation of much $V_2O_4.2SO_3$.

$V_2O_5.3SO_3$ is very deliquescent; soluble in cold water or alcohol; a slight rise of temperature suffices to ppt. $V_2O_5.xH_2O$. By adding to a solution of this salt in cold water the proper quantity of K_2SO_4, G. (*l.c.*) obtained small, amber-yellow crystals, which, after a few washings with cold water, pressure between paper, and drying over H_2SO_4, had the composition of the *double salt* $V_2O_5.2SO_3.K_2O.6aq$. The same crystals were obtained by using the disulphate $V_2O_5.2SO_3$. Replacement of K_2SO_4 by $(NH_4)_2SO_4$ produced the *double salt* $V_2O_5.2SO_3.(NH_4)_2O.4aq$. No double salts were obtained by using Na_2SO_4 or $MgSO_4$, but the trisulphate ($V_2O_5.3SO_3$) crystallised unchanged.

Gerland (*B.* 11, 102) found that when a solution of V_2O_5 in hot. conc. H_2SO_4 was largely diluted and dialysed, H_2SO_4Aq passed rapidly through the dialyser, along with small quantities of V compounds, until the liquid in the dialyser contained V_2O_5 and SO_3 in the ratio $V_2O_5.3SO_3$, after which SO_3Aq passed very slowly through, and the composition of the substance in the dialyser gradually approached $V_2O_5.2SO_3$. By dialysing a diluted solution of V_2O_5 in cold conc. H_2SO_4, the conditions being the same as in the experiment with the hot acid, G. found that SO_3Aq passed through the dialyser regularly, and that, after a time, the ratio of V_2O_5 to SO_3 in the dialyser was 1:1·32. G. supposed these results to mean that a solution of V_2O_5 in cold

H_2SO_4 contains loose, easily decomposed compounds of V_2O_5 and H_2SO_4, but that a solution of V_2O_5 in hot H_2SO_4 contains $V_2O_5.3SO_3$, which gradually loses SO_3 until $V_2O_5.2SO_3$ is formed.

Solutions of V_2O_5 in conc. H_2SO_4 may be reduced to sulphates of lower oxides (Roscoe, *C. J.* [2] 6, 334; Rammelsberg, *B. B.* 1880. 787):—Zn, Cd, or Na-amalgam causes reduction to lavender solutions of $V_2O_2.xSO_3$; Mg effects reduction to green solutions of $V_2O_3.xSO_3$; and H_2S, SO_2, or oxalic acid reduces only to blue solutions of $V_2O_4.xSO_3$.

By fusing V_2O_5 with B_2O_3 (Guyard, *Bl.* [2] 25, 354) obtained a green glass, which he took to be a *vanadic borate*; no analyses or descriptions are given.

The compounds of V_2O_5 with As_2O_5, I_2O_5, P_2O_5, MoO_3, and WO_3 respectively—or some of these compounds—may perhaps be regarded as vanadic arsenates, iodates, &c.; *v.* ARSENO-VANADIC ACIDS AND SALTS, IODO-VANADIC ACIDS, &c., p. 853.

HYPOVANADO-VANADIC OXIDES. Several oxides seem to exist intermediate between V_2O_4 and V_2O_5. Roscoe noticed that V_2O_3 gradually absorbed O and H_2O from the air, forming a greenish solid; Brierley (*C. J.* 49, 30) found that a pale grass-green substance was formed after some months, having the composition $V_2O_4.2V_2O_5.8aq = V_3O_7.4aq$. By dissolving this solid in dilute H_2SO_4Aq, and neutralising by KHOAq, B. obtained $2V_2O_4.4V_2O_5.5K_2O.aq$. By gently heating the compound $2V_2O_4.3V_2O_5.3(NH_4)_2O.6aq$ (*v.* HYPOVANADO-VANADATES, p. 853), B. (*l.c.*) obtained a dark-green solid that absorbed water from the air, and then had the composition $3(V_2O_4.V_2O_5).8aq = 3V_4O_9.8aq$ (*cf.* Ditte, *C. R.* 101, 151; also Manasse, *A.* 240, 23).

Compounds of SO_3 with oxides intermediate between V_2O_4 and V_2O_5 are formed by the reducing action of zinc on solutions of V_2O_5 in H_2SO_4 (*v.* Rammelsberg, *B. B.* 1880. 787).

Vanadium oxyacids, and salts and derivatives thereof. Two oxyacids have been isolated, HVO_3 and $H_4V_2O_7$, corresponding with HPO_3 and $H_4P_2O_7$; salts of these, also salts of the tribasic acid H_3VO_4, and several more complex salts, are known. Salts derived from the hypothetical hypovanadic acid $V_4O_7(OH)_2$ ($= 2V_2O_4.H_2O$) have also been prepared; and several compounds are known which are most simply regarded as $xV_2O_4.yV_2O_5.zMO$, and which may be called hypovanado-vanadates. V_2O_5 also combines with several acidic and basic oxides simultaneously to form compounds of the general form $xV_2O_5.yX{:}xMO$; these compounds are generally described as arseno-vanadates, phospho-vanadates, &c.

VANADIC ACIDS. Two vanadic acids, HVO_3 and $H_4V_2O_7$, have been isolated; salts of the third acid, H_3VO_4, are known, but the acid itself has not certainly been prepared.

Metavanadic acid HVO_3. (*Monobasic vanadic acid. Monohydrate of vanadic oxide* $V_2O_5.H_2O$.) Gerland (*B.* 9, 872 [1876]) prepared this acid by adding an excess of NH_4ClAq to cold $CuSO_4Aq$, then adding NH_4VO_3Aq till a permanent pp. formed, heating to 75°, washing the lustrous yellow scales that slowly separated with dilute H_2SO_4Aq and SO_2Aq (to remove V_2O_4), then washing with water, and drying at 100° until the smell of NH_3 ceased. Manasse (*A.* 240, 52) obtained HVO_3 by decomposing conc. solutions of the Ca, Mg, or Sr salt by a little HNO_3Aq, and washing the pp. with dilute HNO_3Aq, and then with hot water. Metavanadic acid forms golden-yellow crystalline scales; it is unchanged in air; dissolves very slightly in water; insoluble in absolute alcohol; soluble in NH_3Aq, KOHAq, or NaOHAq. By adding NH_4VO_3Aq to $CuSO_4Aq$, filtering from the pp. that formed, and dialysing for several days, Gerland (*l.c.* p. 874) obtained a solution in the dialyser of vanadic acid, which remained clear when heated, and on continued evaporation gave a pp. of red amorphous V_2O_5. Metavanadic acid forms a series of salts (*v.* METAVANADATES, *infra*).

This compound is used as a colour in place of gold bronze, under the name of *vanadium bronze*. According to Guyard (*Bl.* [2] 25, 350), the substance commonly known as vanadium bronze is really an ammonium vanadate.

Pyrovanadic acid $H_4V_2O_7$. (*Tetrabasic vanadic acid. Dihydrate of vanadic oxide* $V_2O_5.2H_2O$.) This acid is obtained by decomposing a fairly conc. solution of an alkali vanadate of the form $M_2V_4O_{11}$ or $M_2V_6O_{16}$ (*v.* TETRAVANADATES and HEXAVANADATES, p. 852) by HNO_3Aq, washing with cold water, and drying in the air (von Hauer, *J. pr.* 80, 324). According to Ditte (*C. R.* 101, 698), the red form of V_2O_5 (*v.* p. 849) absorbs H_2O from the air, forming $V_2O_5.2H_2O$, and also $V_2O_5.5H_2O$. Pyrovanadic acid is described as a brown, amorphous powder, resembling FeO_3H_3; dried over H_2SO_4, it is said to lose half its water. Very slightly soluble in water; the solution is clear yellow; it reddens litmus. $H_4V_2O_7$ is insol. in absolute alcohol; it dissolves readily in NH_3Aq. For salts of this acid *v.* PYROVANADATES (p. 852).

VANADATES. The greater number of the vanadates belong to the series (1) MVO_3, (2) $M_4V_2O_7$, (3) M_3VO_4, (4) $M_2V_4O_{11}$, or (5) $M_2V_6O_{16}$. Series (1), (2), and (3) may be called normal salts; the formulæ may be written as (1) $M_2O.V_2O_5$, (2) $2M_2O.V_2O_5$, and (3) $3M_2O.V_2O_5$. Series (4) and (5) may be called acid salts; the formulæ may be written as (4) $M_2O.2V_2O_5$, and (5) $M_2O.3V_2O_5$. Acid salts are also known intermediate between series (1) and (4); the chief of these are (6) $3M_2O.4V_2O_5 = M_6V_8O_{23}$ ($M_2O{:}V_2O_5 = 1{:}1\frac{1}{3}$), (7) $3M_2O.5V_2O_5 = M_6V_{10}O_{28}$ ($M_2O{:}V_2O_5 = 1{:}1\frac{2}{3}$), and (8) $2M_2O.3V_2O_5 = M_4V_6O_{17}$ ($M_2O{:}V_2O_5 = 1{:}1\frac{1}{2}$). A few salts of the form $4M_2O.V_2O_5 = M_8V_2O_9$ ($M_2O{:}V_2O_5 = 1{:}\frac{1}{4}$) may be called basic salts. Some salts, especially those of Sr and Tl, belong to more complex forms.

Roscoe (*C. J.* [2] 9, 28) has shown that the alkali orthovanadates, M_3VO_4 or $3M_2O.V_2O_5$, are easily decomposed in aqueous solution at the ordinary temperature to pyrovanadates, $M_4V_2O_7$, and MOHAq; but that orthovanadates are formed, rather than meta- or pyro-vanadates, by fusing V_2O_5 with alkali carbonates; further, that aqueous solutions of alkali pyrovanadates are readily decomposed by CO_2 to alkali carbonates and metavanadates.

METAVANADATES M^IVO_3 or $M_2O.V_2O_5$.

Ammonium metavanadate NH_4VO_3. Obtained by dissolving $V_2O_5.xH_2O$ in excess of NH_3Aq, warming, and allowing to evaporate

Forms a white, crystalline crust. Dissolves slowly in cold water, quickly in boiling water. Decomposed by heat, giving V_2O_5 when air is present. According to Berzelius (*P.* 22, 1), when a solution of $V_2O_5.xH_2O$ in excess of NH_3Aq is allowed to evaporate without having been heated, NH_4VO_3 separates in lemon-yellow crystals (*v.* B., *l.c.*; Roscoe, *C. J.* [2] 6, 322; Ditte, *C. R.* 102, 918; Norblad, *B.* 8, 126; Wagner, *D. P. J.* 223, 633; Böttger, *C. C.* 1873 514).

Barium metavanadate $Ba(VO_3)_2.aq$. A yellowish-white pp.; obtained, along with red crystals, by ppg. NH_4VO_3Aq by $BaCl_2Aq$ (Manasse, *A.* 240, 23). Sl. sol. in water. Loses H_2O when heated to c. 200° (Berzelius; Norblad, *l.c.*).

Potassium metavanadate $KVO_3.x$aq. Formed by dissolving V_2O_5 in KOHAq in the ratio V_2O_5:KOH. Various hydrates have been obtained as white crystalline solids, melting to a clear yellow liquid, which solidifies to white, lustrous KVO_3 (*v.* Berzelius, *l.c.*; Ditte, *C. R.* 104, 902, 1061, 1168).

Sodium metavanadate $NaVO_3$. Obtained by Roscoe (*C. J.* [2] 9, 31) by fusing V_2O_5 and Na_2CO_3 in the ratio $V_2O_5:2Na_2CO_3$, dissolving in water, crystallising $Na_4V_2O_7.18$aq, and passing CO_2 into an aqueous solution of this salt, when $NaVO_3$ crystallised out and Na_2CO_3 remained in solution. Small yellowish-white crystals, probably monoclinic prisms, melting readily and solidifying to a yellow crystalline mass (*cf.* Norblad, *l.c.*). Hydrates with 2, 4, and 5 H_2O have been obtained (*cf.* Ditte, *l.c.*).

The other metavanadates that have been prepared are $Cd(VO_3)_2$ (Ditte, *C. R.* 104, 1705); $Ca(VO_3)_2.4$aq (von Hauer, *J. pr.* 69, 385; 80, 324; Manasse, *A.* 240, 23; *cf.* Roscoe, *C. J.* [2] 9, 32); $Co(VO_3)_2.3$aq (D., *l.c.*; Radau, *A.* 251, 114), forms *double salts* with KVO_3 (R., *l.c.*); $Pb(VO_3)_2$ (R., *l.c.*; D., *l.c.*); $LiVO_3.2$aq (Ditte, *C. R.* 104, 1168); $Mg(VO_3)_2.6$aq (D., *l.c.*; Manasse, *l.c.*); $Mn(VO_3)_2.4$aq (Radau, *l.c.*); $AgVO_3.4NH_3.2$aq (D., *l.c.*); $Sr(VO_3)_2.4$aq (Norblad, *l.c.*; Manasse, *l.c.*); $Zn(VO_3)_2.2$aq (D., *l.c.*).

ORTHOVANADATES $M^I_3VO_4$ or $3M_2O.V_2O_5$.

Potassium orthovanadate K_3VO_4. Obtained by fusing V_2O_5 with K_2CO_3; decomposed by water, giving KOHAq and $K_4V_2O_7$ (Rammelsberg, *B. B.* 1883. 3).

Sodium orthovanadate $Na_3VO_4.xH_2O$. Roscoe (*C. J.* [2] 9, 29) obtained the salt with $16H_2O$ by fusing V_2O_5 and Na_2CO_3 in the ratio $V_2O_5:3Na_2CO_3$, allowing to cool, dissolving in as little cold water as possible, quickly adding excess of conc. alcohol, allowing to stand for some hours, washing the crystals that formed with small quantities of alcohol, and drying on a porous plate over H_2SO_4 *in vacuo* (*cf.* Czudnowicz, *P.* 120, 34; Rammelsberg, *B. B.* 1883. 3). Baker (*C. J.* 47, 353) obtained $Na_3VO_4.xH_2O$ with $x=8(?)$, 10, and 12; he also obtained the *double salt* $Na_3VO_4.NaF.19H_2O$. The crystalline forms are given by B., and the various hydrates of Na_3VO_4 are shown to be isomorphous with corresponding arsenates and phosphates. Na_3VO_4Aq changes to $Na_4V_2O_7Aq$ and NaOHAq; the change occurs slowly at ordinary temperatures, and rapidly at higher temperatures (R., *l.c.*).

The other orthovanadates that have been prepared are $Ca_3(VO_4)_2.CaCl_2$ (Hautefeuille, *C. R.* 103, 600; 104, 501); $Pb_3(VO_4)_2$ and $3Pb_3(VO_4)_2.PbCl_2$ (R., *l.c.*); Ag_3VO_4 (R., *l.c.*); Tl_3VO_4 (Carnelley, *C. J.* 26, 323).

PYROVANADATES $M^I_4V_2O_7$ or $2M_2O.V_2O_5$.

Barium pyrovanadate $Ba_2V_2O_7$. Obtained, as a white amorphous powder, by adding $BaCl_2Aq$ to freshly-prepared Na_3VO_4Aq, washing, and drying at 100°. The salt is slightly soluble in water (Roscoe, *C. J.* [2] 9, 33).

Potassium pyrovanadate $K_4V_2O_7$. Hard, deliquescent monoclinic prisms, formed by adding KOHAq to KVO_3Aq, rapidly evaporating to a syrup, and placing over H_2SO_4 (Norblad, *B.* 8, 126).

Sodium pyrovanadate $Na_4V_2O_7.16H_2O$. Formed by fusing V_2O_5 and Na_2CO_3 in the ratio $V_2O_5:2Na_2CO_3$, dissolving, and crystallising; also by exposing Na_3VO_4Aq to air free from CO_2 until addition of alcohol ppts. silky scales ($Na_4V_2O_7$) (Roscoe, *l.c.*, p. 31). White six-sided tables; e. sol. water, insol. alcohol. $Na_4V_2O_7Aq$ is decomposed by CO_2 to Na_2CO_3Aq and $NaVO_3Aq$ (R., *l.c.*).

The other pyrovanadates that have been prepared are $2Ca_2V_2O_7.5$aq (Roscoe, *l.c.*; *cf.* Ditte, *C. R.* 104, 1705); $Cu_2V_2O_7.3$aq (von Hauer, *l.c.*); $Pb_2V_2O_7$ (Ditte, *l.c.*); $2Pb_2V_2O_7.PbO$ (Roscoe, *l.c.*); $Li_4V_2O_7.6$aq (von H., *l.c.*); $Mn_2V_2O_7$ (Ditte, *l.c.*); $Ag_4V_2O_7$ (Roscoe, *l.c.*; Ditte, *l.c.*); $Tl_4V_2O_7$ (Carnelley, *C. J.* 26, 323); $Zn_2V_2O_7$ (D., *l.c.*).

TETRAVANADATES $M_2^IV_4O_{11}$ or $M_2O.2V_2O_5$ (also called *divanadates*).

Ammonium tetravanadate $(NH_4)_2V_4O_{11}.x$aq; $x=3$ or 4. Formed by adding a little acetic acid to boiling NH_4VO_3Aq and evaporating *in vacuo*; also by saturating NH_3Aq with V_2O_5 in a closed, warmed flask, and allowing to evaporate; red prismatic crystals with a golden-yellow sheen (Berzelius, *P.* 22, 1; Rammelsberg, *B. B.* 1883. 3; von Hauer, *l.c.*; Ditte, *C. R.* 102, 918).

Potassium tetravanadate $K_2V_4O_{11}.x$aq; $x=3$, 4, 7, and 10. Obtained by saturating K_2CO_3Aq at 80° with excess of V_2O_5 and allowing to cool; also by adding acetic acid to V_2O_5 in KOHAq, concentrating at 80°, and letting cool (Ditte, *C. R.* 104, 902, 1061, 1168; *cf.* Norblad, *B.* 8, 126). Orange-coloured tablets (*v.* also Gibbons, *C. N.* 30, 267).

The other tetravanadates are $CaV_4O_{11}.9$aq (Manasse, *A.* 240, 23); PbV_4O_{11} (Ditte, *l.c.*); $Li_2V_4O_{11}.9$aq (Norblad, *l.c.*); $MgV_4O_{11}.9$aq. (B., *l.c.*; von Hauer, *l.c.*); $NiV_4O_{11}.3$aq (Radau, *A.* 251, 114); $Na_2V_4O_{11}.9$aq (Berzelius, *P.* 22, 1; von Hauer, *l.c.*; Norblad, *l.c.*); $SrV_4O_{11}.9$aq (B., *l.c.*; von H., *l.c.*).

HEXAVANADATES $M_2^IV_6O_{16}.xH_2O$ or $M_2O.3V_2O_5.xH_2O$ (also called *trivanadates*). These salts have been described by Norblad (*B.* 8, 126) and Ditte (*C. R.* 104, 902, 1061, 1168). The chief are those where $M_2=(NH_4)_2$, Cd, Ca, K_2 and Na_2.

The principal vanadates belonging to other series than those already mentioned are the following:—(1) $3M_2O.4V_2O_5$ $(=M_3^{II}V_8O_{23})$, M = Ca and Sr (*v.* Manasse, *l.c.*); (2) $3MO.5V_2O_5$ $(=M^{II}_3V_{10}O_{28})$, M = Ba, Mg, K_2 (*v.* Manasse, *l.c.*; Radau, *A.* 251, 114); (3) $2MO.3V_2O_5$ $(=M^{II}_2V_6O_{17})$, M = $(NH_4)_2$, Ba, Li_2, Mg, K_2, Na_2 (*v.* Ditte, *l.c.*; also *C. R.* 96, 1048; Manasse, *l.c.*; Norblad, *l.c.*); (4) $4M_2O.V_2O_5(=M^I{}_8V_2O_9)$, $M=Li$ and Na (*v.* Ditte, *l.c.*).

Several other vanadates not belonging to any of these series have also been described; for Ca and Sr salts (and double salts), *v.* Manasse (*l.c.*); and for Tl salts *v.* Carnelley (*C. J.* 26, 323).

HYPOVANADATES. Salts of hypothetical hypovanadic acid $V_4O_7(OH)_2$ $(=2V_2O_4.H_2O)$. These salts belong to the form $M^I{}_2V_4O_9.xH_2O$ $(=M_2O.2V_2O_4.xH_2O)$. The formation of the NH_4 and K salts was described by Berzelius; a series of salts was prepared and examined by Crow (*C. J.* [2] 15, 458). The alkali salts are obtained by treating fairly conc. VO_2ClAq (*v.* HYDRATED VANADIUM DIOXYMONOCHLORIDE, p. 854) with excess of caustic alkalis, allowing the pps. to settle in closed vessels, washing with alkali solution, then with dilute alcohol containing a little acetic acid, and finally with alcohol alone, and drying between paper. The salts of Pb and Ag are obtained by ppn. from a solution of the K salt. The salts form brown to black crystalline powders; the alkali salts dissolve in water. Crow prepared salts with $M_2=(NH_4)_2$, Ba, Pb, K_2, Ag_2, and Na_2.

HYPOVANADO-VANADATES. Salts of the form $nV_2O_4.mV_2O_5.pM_2O.xH_2O$. Alkali salts of this series were obtained by Brierley (*C. J.* 49, 32) by reducing V_2O_5Aq by SO_2, adding V_2O_5 in alkali, then a slight excess of alkali, and then acetic acid; pouring into alkali acetate solution, washing the pps. with alcohol, and drying over $CaCl_2$. The salts crystallise in greenish-black, or black, prisms. The following were prepared: (1) $2V_2O_4.V_2O_5.2Na_2O.13H_2O$; (2) $2V_2O_4.V_2O_5.2K_2O.6H_2O$; (3) $2V_2O_4.2V_2O_5.(NH_4)_2O.14H_2O$; these salts are soluble in water: (4) $2V_2O_4.4V_2O_5.5K_2O.H_2O$; (5) $2V_2O_4.4V_2O_5.3(NH_4)_2O.6H_2O$; these are insoluble in water.

COMPLEX VANADIC ACIDS AND SALTS. Vanadic oxide V_2O_5 combines with several anhydrides, such as As_2O_5, I_2O_5, P_2O_5, &c., and many of the compounds thus produced combine with basic oxides. The compounds of V_2O_5 with certain anhydrides are generally regarded as acidic; and the compounds formed of V_2O_5, anhydrides, and bases are usually classed as salt-like substances. It is quite likely that many of the compounds of V_2O_5 with anhydrides, such as As_2O_5, P_2O_5, &c., would be better classed as salts, just as the compounds of V_2O_5 with SO_3 are classed as salts.

Arseno-vanadic acids and salts. By boiling V_2O_5 with excess of H_3AsO_4Aq, and concentrating the solution, Fernandez (*B.* 17, 1632) obtained lustrous, golden-yellow crystals of $V_2O_5.As_2O_5.11aq$ (*cf.* Friedheim a. Schmitz-Dumont, *B.* 23, 2600). Gibbs (*P. Am. A.* 21, 50) obtained $xV_2O_5.yAs_2O_5.zaq$ (x and y probably either 5 and 8, or 7 and 6), by decomposing a mixture of Na vanadate and arsenate by HNO_3Aq. For various compounds of the form $mV_2O_5.nAs_2O_5.pMO$, where m and n are 1 and 1, 2 and 3, 1 and 2, 2 and 1, &c., and p varies from 1 to 5, *v.* F. a. S.-D. (*l.c.*).

Iodo-vanadic acids. Ditte (*C. R.* 102, 757) says that compounds of V_2O_5 and I_2O_5 are formed by heating V_2O_5 with conc. HIO_3Aq; he gives formulæ, but no analyses.

Molybdo-vanadic acids and salts. For descriptions of numerous compounds of the forms $xV_2O_5.yMoO_3.zaq$, $xV_2O_5.yMoO_3.pMO.zaq$, and also $xV_2O_5.yMoO_3.mP_2O_5.pMO.zaq$, *v.* Gibbs (*P. Am. A.* 18, 232).

Phospho-vanadic acids and salts. Various compounds of V_2O_5, P_2O_5, and H_2O are described by Gibbs (*P. Am. A.* 21, 50); Ditte (*C. R.* 102, 757) also assigned formulæ to substances obtained by heating V_2O_5 with conc. H_3PO_4. Friedheim (*B.* 23, 1530) obtained $V_2O_5.P_2O_5.2H_2O$ by dissolving V_2O_5 in syrupy H_3PO_4.

For descriptions of a great many compounds of the form $xV_2O_5.yP_2O_5.nMO.zaq$, *v.* Gibbs (*l.c.*); and *cf.* Friedheim (*l.c.*).

F. divides the compounds formed by reacting with V_2O_5 on alkali phosphates into two classes, which he calls *luteo-* and *purpureo- compounds.*

Luteo- compounds are formed by (1) the interactions of phosphoric and vanadic acids in solution; (2) the interactions of solutions of phosphates and vanadates in presence of small quantities of acids; (3) the interactions of solutions of phosphates and vanadic acid; (4) the interactions of vanadates and phosphoric acid, by heating solutions nearly to boiling and evaporating. These compounds are yellow, granular, and indistinctly crystalline; the alkali compounds are very slightly soluble in water, solution being accompanied by decomposition. The following luteo- compounds are described by F.:

$V_2O_5.P_2O_5.2H_2O.9aq$,
$V_2O_5.P_2O_5.(NH_4)_2O.H_2O.2aq$,
$2V_2O_5.P_2O_5.(NH_4)_2O.7aq$,
$V_2O_5.P_2O_5.K_2O.H_2O.2aq$, and
$2V_2O_5.P_2O_5.K_2O.7aq$.

Purpureo- compounds are formed by dissolving vanadic acid in conc. solutions of alkali phosphates, and by adding phosphoric acid to conc. solutions of alkali vanadates; in each case the solutions should be strongly heated. The purpureo- compounds described by F. belong to the form $12V_2O_5.P_2O_5.7M_2O.26aq$; they are dark-red crystalline substances, sol. in water.

F. regards the luteo- compound of the form $V_2O_5.P_2O_5.2H_2O.9aq$ as acid phosphate of the radicle VO_2, thus $(VO_2)H_2PO_4.9aq$; he compares this with the acid orthophosphates MH_2PO_4. The compounds of the form $V_2O_5.P_2O_5.M_2O.H_2O.xaq$ are looked on as double acid phosphates of alkali metal and VO_2, thus $NH_4(VO_2)HPO_4$. The luteo- compounds $2V_2O_5.P_2O_5.M_2O.xaq$ are formulated by F. as double compounds of alkali metavanadates and $(VO_2)H_2PO_4$; thus $2V_2O_5.P_2O_5.K_2O.2H_2O.5aq = 2(KVO_3.(VO_2)H_2PO_4.2\frac{1}{2}aq)$. The purpureo- compounds which belong to the form $12V_2O_5.P_2O_5.7M_2O.xaq$ are looked on by F. as double compounds of acid vanadates and acid phosphates; this view of their constitution is expressed by the statement

$$12V_2O_5.P_2O_5.7M_2O.xH_2O = P_2O_5.2M_2O.H_2O + 12V_2O_5.5M_2O + (x-1)H_2O.$$

These views of F. are considerably modified in a later paper (*Zeit. f. anorg. Chemie*, 5, 437), where the purpureo- compounds are looked on as divanadates with some V_2O_5 isomorphously replaced by P_2O_5. According to F., many of the substances described by Gibbs and by Ditte do not exist.

Berzelius (*P.* 22, 1) described a compound of V_2O_5, P_2O_5, and SiO_2, with H_2O, which may be named *phospho-silico-vanadic acid.*

TUNGSTO-VANADIC ACIDS AND SALTS. The compounds of V_2O_5 with WO_3 and bases that have been described are very numerous, and the formulæ given are generally extremely complex (*v.* Gibbs, *P. Am. A.* 18, 232; Rosenheim, *A.* 251, 197, 234; and especially Friedheim, *B.* 17, 1505; 23, 1505; 24, 1173).

Vanadium, oxybromides of. Two compounds of V with O and Br have been isolated; $VOBr_2$ and $VOBr_3$, corresponding with two of the five oxychlorides. According to Schafarik (*W. A. B.* 33, 14; 47 [11] 251), other oxybromides also exist.

VANADIUM OXYDIBROMIDE $VOBr_2$. (*Vanadyl dibromide.*) A brown, deliquescent powder. Prepared by heating $VOBr_3$ (*v. infra*); decomposition to $VOBr_2$ and Br occurs slowly at temperatures below 180°, and suddenly at 180°. Heated in air forms V_2O_5; dissolves in water, forming a blue solution (Roscoe, *C. J.* [2] 9, 26). Ditte (*C. R.* 102, 1310) says that a compound $VOBr_2.4H_2O$ is formed, as dark-green, deliquescent crystals, by treating red V_2O_5 with HBr. D. writes the formula $V_2O_3Br_2.2HBr.7H_2O$.

VANADIUM OXYTRIBROMIDE $VOBr_3$. (*Vanadyl tribromide.*) Prepared by passing vapour of pure Br over V_2O_3 heated to redness, condensing the yellowish-white vapours that are formed, removing excess of Br from the red liquid by heating to 40°–50° at c. 100 mm. pressure in a current of perfectly dry air, and then distilling *in vacuo* (Roscoe, *C. J.* [2] 9, 24). $VOBr_3$ is a red, very hygroscopic liquid that boils at 130°–136° at 100 mm. pressure; S.G. 2·9673 at 0°, 2·9325 at 14·5°; decomposes slowly at the ordinary temperature, and suddenly at 180°, to $VOBr_2$ and Br (R., *l.c.*).

Vanadium, oxychlorides of. Five compounds of V with O and Cl have been isolated: VOCl, $VOCl_2$, $VOCl_3$, V_2O_2Cl, and $VO_2Cl.x$aq.

VANADIUM OXYMONOCHLORIDE VOCl. (*Vanadyl monochloride.*) Obtained by the regulated reduction of $VOCl_3$ by H. The mixed vapours are passed through a red-hot tube; VOCl is deposited near the end whereat the vapours enter the tube. A brown, light, flocculent powder; insol. in water; easily dissolved by HNO_3Aq (Roscoe, *C. J.* [2] 6, 347).

VANADIUM OXYDICHLORIDE $VOCl_2$. (*Vanadyl dichloride.*) Prepared by heating a slight excess of $VOCl_3$ with zinc for some days in a sealed tube, at 400°, cutting off the part of the tube on which the sublimate of $VOCl_2$ has formed (V_2O_4 and $ZnCl_2$ are the other products), quickly placing it in a wider tube, and removing $VOCl_3$ by heating in a stream of dry CO_2 at 130°. Also obtained by passing vapour of $VOCl_3$ and H through a red-hot tube; $VOCl_2$ is deposited near the end of the tube whereat the gases enter, and V_2O_2Cl at the further end of the tube (Roscoe, *l.c.*, p. 348). Lustrous, grass-green, deliquescent tablets; S.G. 2·88 at 13°; slowly decomposed by water; soluble in dilute HNO_3Aq. A compound with $PtCl_4$, having the composition $2(VOCl_2.PtCl_4).21$aq, is said by Brauner (*M.* 3, 58) to be formed by dissolving V_2O_5 in conc. HClAq in presence of $PtCl_4$Aq.

VANADIUM OXYTRICHLORIDE $VOCl_3$. (*Vanadyl trichloride.*) Mol. w. 173·27.

Formation.—1. By heating V_2O_3 gently in a stream of Cl (Berzelius, *P.* 22, 1).—2. By heating a mixture of V_2O_5 and C in Cl.

Preparation.—A mixture of V_2O_5 and sugar-charcoal is heated to redness in a stream of dry H, and allowed to cool in that gas; a stream of dry Cl is then passed over the mixture, which is heated to redness, and the product is condensed; the liquid thus obtained is heated for some hours in a flask with an inverted condenser, in a current of dry CO_2, and then rectified over Na (Roscoe, *C. J.* [2] 6, 342).

Properties and Reactions.—A clear, mobile, lemon-yellow liquid (Berzelius, *l.c.*; Roscoe, *l.c.*; Schafarik, *A.* 109, 85). S.G. 1·836 at 17·5°, 1·828 at 24° (R., *l.c.*); 1·86534 at $\frac{0^\circ}{0^\circ}$, 1·63073 at b.p. (Thorpe, *C. J.* 37, 348). B.P. 127·19° (T., *l.c.*). S.V. 106·25. Does not solidify above −15° (R., *l.c.*). V.D. 88·38 at 186° (R., *l.c.*; *cf.* T., *C. N.* 24, 827; Schafarik, *l.c.*). Gives off thick, yellowish-red fumes in the air. Dissolves in a little water, forming a thick, red liquid; dissolves in much water, forming a clear yellow liquid; dissolves in absolute alcohol with a red colour, but the solution soon becomes blue, owing to reduction. Heated to 60°–70° in a closed tube with ether forms needles of the composition $VOCl_3.Et_2O$ (Bedson, *C. J.* 29, 309).

DIVANADIUM DIOXYMONOCHLORIDE V_2O_2Cl. (*Divanadyl monochloride.*) Yellow-bronze, microscopic crystals, resembling *mosaic gold*; formed by passing $VOCl_3$ and H through a red-hot tube. The crystals are deposited on the part of the tube farthest from the end whereat the gases enter (Roscoe, *C. J.* [2] 6, 348). Insoluble in water; soluble in HNO_3Aq. This compound was thought by Schafarik (*A.* 109, 85) to be V.

HYDRATED VANADIUM DIOXYMONOCHLORIDE $VO_2Cl.x$aq. (*Hypovanadic chloride* $V_2O_4Cl_2.x$aq.) Formed, as a brown, deliquescent solid, by passing H_2S into a solution of V_2O_5 in hot HClAq, filtering from S, and evaporating (Crow, *C. J.* 30, 457). Heated in a stream of dry CO_2 gives off HCl and H_2O, and leaves V_2O_4. C. (*l.c.*) gives the hydration as $V_2O_4Cl_2.5$aq.

Vanadium, oxyfluorides of. No compound of V with O and F has been isolated with certainty. V_2O_2 dissolves in excess of HFAq; on evaporation, solution in water, and evaporation over H_2SO_4, Petersen (*J. pr.* [2] 40, 194) obtained blue, microscopic crystals which he supposed might be $VOF_2.x$aq, inasmuch as a solution of these crystals in HFAq treated with fluorides yielded salts of the form xMF.yVOF$_2$ (*v.* HYPOVANADOXYFLUORIDES, p. 845). P. did not obtain enough of the blue crystals for analysis.

Vanadium, oxyiodides of. According to Ditte (*C. R.* 102, 1310), an oxyiodide $2VOI_2.9H_2O$ is formed, as a black, deliquescent mass, by adding excess of HIAq to a warm solution of red V_2O_5, removing free I by shaking with finely-divided Ag, filtering, and evaporating *in vacuo*. The compound is said to react with NH_3Aq, giving $(NH_4)_2V_4O_9$. D. writes the formula as $V_2O_2I_2.2HI.8H_2O$; but no analyses are given.

No reaction occurs when I is heated with V_2O_3 (Roscoe, *C. J.* [2] 9, 28); nor when V_2O_5 is digested with water, or alcohol, and I (Guyard, *Bl.* [2] 25, 351). V_2O_5 and I_2O_5 probably combine (*v.* Ditte, *C. R.* 102, 757, 1019).

Vanadium, oxysulphides of. None of these compounds has been certainly isolated. Oxysulphides may perhaps be formed by decomposing alkali thiovanadates in solution by dilute acids (*v.* Kay, *C. J.* 37, 728).

Vanadium, salts of. Compounds of the oxides V_2O_3, V_2O_4, and V_2O_5 with acidic oxides have been isolated; the formulæ of one or two of the compounds may be written as derived from oxyacids by replacing H by V, but it is simpler, and more in keeping with the facts that are known, to represent all the compounds by the general formula $V_2O_x.yX$, where X is an acidic oxide. The best-studied compounds of V_2O_4 with acidic oxides may be represented as salts of the radicle V_2O_2 (divanadyl), or of the radicle VO (vanadyl); and the compounds of V_2O_5 with acidic oxides as acid salts of the radicle VO_2. The sulphates have been better studied than the other salts; the following table presents the compositions of the sulphates.

I. *Vanadous sulphates* (*v.* p. 847):
$V_2O_3.4SO_3.x\text{aq} = V_2H_2(SO_4)_4.y\text{aq}$ $(y = x - 1)$;
??$V_2O_3.3SO_3 = V_2(SO_4)_3$.

II. *Hypovanadic sulphates* (*v.* p. 848):
$V_2O_4.2SO_4 = V_2O_2.(SO_4)_2 = (VO)SO_4$;
$V_2O_4.3SO_3.x\text{aq} = V_2O_2.H_2(SO_4)_3.y\text{aq}$ $(y = x - 1)$
$= (VO.SO_4)_2.H_2SO_4.y\text{aq}$.

III. *Vanadic sulphates* (*v.* p. 850):
$V_2O_5.2SO_3 = (VO_2)_2SO_4.SO_3$; or if the salt contains $x$aq, then $V_2O_5.2SO_3.x\text{aq} =$
$(VO_2)_2SO_4.H_2SO_4.y\text{aq}$ $(y = x - 1)$;
$V_2O_5.3SO_3 = (VO_2)_2SO_4.2SO_3$; or if the salt contains $x$aq, then
$V_2O_5.3SO_3.x\text{aq} = (VO_2)_2SO_4.2H_2SO_4.yH_2O$
$(y = x - 2)$.

Alkalis probably ppt. $V_2O_3.x\text{aq}$ from solutions of vanadous sulphates (*v.* p. 847); from solutions of hypovanadic sulphates alkalis ppt. $V_2O_4.x\text{aq}$ (*v.* p. 848).

V_2O_2 dissolves in oxyacids, forming lavender solutions which probably contain $V_2O_2.xX$, where X is an acidic oxide (*v.* p. 846).

Various salts of V_2O_3, V_2O_4, and V_2O_5 besides the sulphates probably exist, but they have not been thoroughly examined (*v.* Hypovanadic salts, p. 848; Vanadic salts, p. 850; Arseno-vanadic acids and salts, p. 853; Iodo-vanadic acids, p. 853; Molybdo-vanadic acids and salts, p. 853; Phospho-vanadic acids and salts, p. 853; and Tungsto-vanadic acids and salts, p. 854).

Vanadium, silicide of. Roscoe (*C. J.* [2] 8, 358) says that V acts on glass or porcelain vessels when strongly heated therein, forming a compound with Si; tubes in which V chlorides are reduced by heating in H get coated with a grey lustrous mirror of this compound. No details or analyses are given.

Vanadium, silicofluoride of. By boiling V_2O_3 with H_2SiF_6Aq and alcohol, Guyard (*Bl.* [2] 40, 352) obtained a greyish, uncrystallisable mass which he took to be a silicofluoride of V; no analyses or details of preparation are given.

Vanadium, sulphides of. Berzelius (*P.* 22, 1) described two compounds of V and S, one obtained by ppg. a solution of an alkali thiovanadate by dilute acid, and the other by heating V_2O_3 in H_2S. B. gave the formulæ VS_2 and VS_3 to the compounds he described. The sulphides of V were re-examined by Kay in 1880 (*C. J.* 37, 728), who found that the pp. obtained by adding dilute HClAq or H_2SO_4Aq to a solution of sodium vanadate saturated with H_2S, or to solution of V_2O_5 in an alkali hydrosulphide, contained O, but probably had not a definite composition; and that the product of heating V_2O_3 in H_2S is the trisulphide V_2S_3; Kay prepared three sulphides, V_2S_2, V_2S_3 and V_2S_5, corresponding to three of the four oxides; the sulphides dissolve in solutions of alkali sulphides, probably forming *thiovanadates* (*q. v. infra*).

Vanadium disulphide V_2S_2. (*Hypovanadous sulphide.*) Prepared by heating V_2S_3 to full redness, for a long time, in H quite free from O. Forms black lustrous plates, or a brownish-black powder; S.G. 4·2 to 4·4. Absorbs O very quickly when heated in air, giving V_2O_3, V_2O_4, and then V_2O_5, with evolution of SO_2. Not acted on by boiling HClAq, dilute or conc., nor by boiling dilute H_2SO_4Aq, or cold conc. H_2SO_4. Dissolves in hot conc. H_2SO_4; dissolves in HNO_3Aq. Slowly acted on by NaOHAq or KOHAq, hot or cold; dissolves in $(NH_4)_2S$Aq or KHSAq, forming purple to reddish-brown solutions (Kay, *l.c.* p. 735).

Vanadium trisulphide V_2S_3. (*Vanadous sulphide.*) Formed by strongly heating V_2O_3 in a stream of H_2S (Berzelius, *l.c.*; Kay, *l.c.* p. 736); also by heating any chloride of V or $VOCl_3$, to redness in H_2S (K., *l.c.*); and by strongly heating V_2O_5 in a stream of vapour of CS_2 so long as any reaction occurs (K., *l.c.*). Forms dark, lustrous plates, or a black amorphous powder; S.G. 3·7 to 4·0. Oxidised by heating in air, finally to V_2O_5, giving off SO_2. Scarcely acted on by dilute HClAq or H_2SO_4Aq, hot or cold, nor by conc. HClAq; readily oxidised by HNO_3Aq. Soluble in $(NH_4)_2S$Aq or KHSAq, forming purple-red to golden-red solutions; also somewhat soluble in KOHAq, NaOHAq or NH_4OHAq (Kay, *l.c.*).

Vanadium pentasulphide V_2S_5. (*Vanadic sulphide.*) Prepared by mixing V_2S_3 with ⅔ its weight of pure powdered S, heating to fusion (c. 400°) in a narrow tube quite filled with CO_2 and sealed, cooling, and dissolving out excess of S with CS_2. A black powder; S.G. 3·0. Heated in a gas that does not react with it, V_2S_5 gives off S and leaves V_2S_3; heated in air gives off SO_2, forming V_2O_3 and finally V_2O_5. Behaves towards acids similarly to V_2S_3. Dissolves in hot NaOHAq; also in $(NH_4)_2S$Aq or KHSAq, forming yellow to red solutions (Kay, *l.c.* p. 738).

Vanadium thio-acids, and salts thereof. No compound of V with H and S has been isolated, but some thiovanadates, and also some oxythiovanadates, have been prepared by Krüss a. Ohnmais (*B.* 23, 2547).

Ammonium thio-orthovanadate $(NH_4)_3VS_4$. Obtained, in purple crystals, resembling $KMnO_4$, S.G. 1·62, by passing H_2S into a solution of NH_4VO_3 in NH_3Aq S.G. ·898; the solution is saturated in the cold, and is kept cold while H_2S is passed in. A brown pp. is formed, and this dissolves after passing in more H_2S to a dark-violet liquid, from which the salt crystallises after some time.

Sodium monoxy-thio-orthovanadate $Na_3VOS_3.5\text{aq}$. Obtained by saturating 80 c.c

NaOHAq S.G. 1·122, with H_2S, adding a solution of 3 g. $Na_4V_2O_7$ in 6 c.c. water, cooling the liquid by ice, and passing in H_2S for 4 hours. The salt was also obtained without water of crystallisation by Krüss (*Zeit. f. anorg. Chemie*, 3, 264) by fusing a mixture of V_2O_5, Na_2CO_3, and S, until excess of S was removed. Small crystals, that melt at the ordinary temperature to a red, oily liquid (K. a. O., *l.c.*).

Sodium trioxy-thio-orthovanadate Na_3VO_3S. 10aq. Obtained by heating $Na_4V_2O_7Aq$ to boiling, adding freshly prepared NaSHAq, cooling by ice, and adding alcohol. A red oil, that solidifies to a crystalline mass which melts at 18° (K. a. O., *l.c.*).

Ammonium monoxy-thio-pyrovanadate $(NH_4)_4V_2OS_6$. Formed by passing H_2S into a cooled solution of NH_4VO_3 in NH_3Aq S.G. greater than ·898, and allowing the liquid to stand for some months, when crystals separate having S.G. 1·715 (K. a. O., *l.c.*).

Potassium monoxy-thio-pyrovanadate $K_4V_2OS_6$. 3aq. Obtained by passing H_2S into KVO_3 in KOHAq S.G. 1·472, air being excluded and the liquid cooled by ice. Crystals resemble $KMnO_4$; S.G. 2·144; loses all water slowly at 150°. By evaporating the mother-liquor from this salt *in vacuo*, large crystals of the salt $2K_4V_2OS_6$. 3aq are obtained (K. a. O., *l.c.*).

VANADOXYFLUORIDES and *Hypovanadoxyfluorides*; *v.* pp. 844–5.

VANADYL COMPOUNDS; compounds of the radicle VO: *v.* Vanadium oxybromides (p. 854), Vanadium oxychlorides (p. 854), and Hypovanadic salts (p. 848).

VANILLIC ACID *v. Methyl derivative* of Protocatechuic acid.

VANILLIN *v. Methyl derivative* of Protocatechuic aldehyde.

VANILLO-DIACETONAMINE *v.* Acetonamine.

VAPOUR DENSITIES. The term 'vapour density' is now generally employed to signify the specific gravity of a gas referred to hydrogen as unity. For descriptions of the principles of the methods used in determining vapour densities, *v.* Densities, relative, vol. ii. p. 374; and for an account of the application of vapour densities to finding molecular weights, *v.* Atomic and molecular weights, vol. i. p. 340.

VEGETABLE PROTEÏDS *v.* Proteïds.

VERATRALBINE *v.* Jervine.

VERATRIC ACID *v. Di-methyl derivative* of Protocatechuic acid.

Homo-veratric acid *v.* Di-oxy-phenyl-acetic acid.

VERATROLE *v. Di-methyl ether* of Pyrocatechin.

VERATRUM ALKALOIDS.

Veratrine $C_{32}H_{49}NO_9$. *Cevadine.* [205°]. S. ·12 at 15° Occurs in the seeds of *Veratrum Sabadilla* (Meissner, *N. J. T.* 5, 3; Pelletier a. Caventou, *A. Ch.* [2] 14, 69; Couerbe, *A. Ch.* [2] 52, 352; Merck, *A.* 95, 200; *Ar. Ph.* 231, 135; Delondre, *J. Ph.* [3] 27, 417; Weigelin, *C. C.* 1872, 229; Schmidt, *Ar. Ph.* [3] 10, 511; *B.* 9, 1115; *A.* 185, 224). Occurs also in the root of *Sarracenia purpurea* (St. Martin, *Z.* [2] 2, 442; Hétet, *C. R.* 88, 185). Prepared by extracting the seeds with boiling alcohol containing a little tartaric acid, concentrating the extract, adding water, filtering from resin, adding Na_2CO_3, and shaking with ether. The ethereal solution is shaken with dilute tartaric acid solution, and the acid solution mixed with Na_2CO_3 and extracted with ether. The ethereal extract is mixed with ligroïn and allowed to evaporate spontaneously, when a viscid mass first separates, followed by crystals which are recrystallised from alcohol (Wright a. Luff, *C. J.* 33, 338). If commercial veratrine [144°] be dissolved in alcohol at 70°, water added till turbidity ensues, and the solution evaporated at 50° to 60°, crystalline veratrine separates first, then a resinous mixture of veratrine and veratridine, while the mother-liquor contains veratridine and veratroïn veratrate (Rosetti, *Ar. Ph.* [3] 21, 81).

Properties.—Needles (from alcohol), sol. ether, insol. water. Inactive to light. Very poisonous, a small quantity producing vomiting and purging. Introduced into the nose it produces sneezing. Alkaline to test papers. Conc. H_2SO_4 forms a yellow colour changing to crimson, 1 pt. colouring 3,000 pts. H_2SO_4 (Vasmer, *Ar. Ph.* 2, 74). Conc. HClAq forms a violet solution on warming. HNO_3 forms a red solution, becoming yellow. Veratrine mixed with sugar (3 pts.) is coloured by H_2SO_4 dark green and finally deep blue (Weppen, *Fr.* 13, 454). A solution of ammonium selenite (1 g.) in H_2SO_4 (20 c.c.) gives a yellow colour at 30°; in 3 hours a red pp. is formed, the liquid remaining yellow (Da Silva, *C. R.* 112, 1267). On heating with alcoholic potash or baryta it yields angelic acid and cevine (W. a. L.; Rosetti; Stransky, *M.* 11, 482). ICl forms a yellow flocculent pp., sol. hot HClAq (Dittmar, *B.* 18, 1612). Conc. HClAq yields tiglic acid. Veratrine yields tiglic acid and (β)-methyl-pyridine on distillation. On distilling veratrine with lime the products are (β)-methyl-pyridine and its hexahydride and isobutyric acid (Ahrens, *B.* 23, 2705). Veratrine is not affected by boiling dilute H_2SO_4.

Salts.—B'HCl. Amorphous.—$B'_2H_2PtCl_6$: amorphous.—$B'HAuCl_4$. Yellow needles (from alcohol).—$B'HAuCl_4$ 2aq (Rosetti, *J.* 1883, 1351).—$B'HHgCl_3$. Crystalline pp., v. sol. alcohol.—$B'_2H_2SO_4$ (dried at 100°).—$B'HI_3$. Reddish-brown amorphous solid (Bauer, *J.* 1874, 861).

Benzoyl derivative $C_{32}H_{48}BzNO_9$. [170°–180°]. Brown crystals (containing 1½ aq) (from ether).—$B'HAuCl_4$.

Dibromide $C_{32}H_{49}Br_2NO_9$. Formed by allowing the tetrabromide to stand in contact with dilute KOHAq. Light-yellow amorphous solid.

Tetrabromide $C_{32}H_{49}Br_4NO_9$. Formed by shaking veratrine with bromine-water. Yellow amorphous powder, insol. water, v. sol. alcohol and ether (Ahrens, *B.* 23, 2701).

Cevine $C_{27}H_{43}NO_8$ (W. a. L.); $C_{27}H_{44}NO_8$ (Rosetti). *Cevedine.* [145°] (W. a. L.); [182°–185°] (R.). Formed by boiling veratrine with alcoholic NaOH (W. a. L.). Yellow resin, v. sol. alcohol, sl. sol. ether. Its aqueous solution becomes turbid on warming. Does not attack the mucous membrane, gives a crimson colour with H_2SO_4, and a brown colour with cane-sugar and H_2SO_4. Its salts are amorphous.—$B'HHgI_3$ (dried at 100°). Precipitate.

Veratridine $C_{37}H_{53}NO_{11}$ (W. a. L.); $C_{32}H_{49}NO_9$ (Rosetti). *Veratrine.* [180° cor.] (W. a. L.); [150°-155°] (R.). S. 3 at 15°. If the viscid mass which separates before veratrine when a solution of the crude base in alcohol-ligroïn is evaporated be shaken with ether, cevadilline remains undissolved, while veratridine dissolves in the ether (Wright a. Luff). Amorphous resin, sl. sol. ether. Decomposed by alcoholic potash into veratric acid and verine $C_{28}H_{45}NO_8$ [c. 95°] (W. a. L.) or veratroïn $C_{55}H_{92}N_2O_{16}$ [143°-148°] (R.), an amorphous base, sol. ether. Veratridine dissolves in boiling water, being converted into veratroïn veratrate $C_{55}H_{92}N_2O_{16}C_9H_{10}O_4$ 2aq (Rosetti), which melts, when anhydrous, at 165°-170°. H_2SO_4 forms a yellow solution which turns crimson.—Salts.—$B'HAuCl_4$. Amorphous.—$B'H_2SO_4$ 10aq, crystalline.

Cevadilline $C_{34}H_{53}NO_8$. Obtained as above (W. a. L.). Amorphous, sl. sol. ether, m. sol. benzene. Decomposed by alcoholic potash.

Salts.—$B'HAuCl_4$.—$B'HHgI_3$. Gelatinous. Cevadilline is perhaps identical with the sabadilline $C_{41}H_{66}N_2O_{13}$ of Wiegelin (*C. C.* 1872, 229), to which Hesse (*A.* 192, 186) assigns the formula $C_{21}H_{35}NO_7$; while sabatrine $C_{51}H_{86}N_2O_{17}$ (W.) or $C_{26}H_{45}NO_9$ (H.) was probably a mixture of decomposition-products (Wright a. Luff).

Veratrum album. The alkaloids in the root of this plant, and in that of *V. viride*, are described under JERVINE.

VERATRUMIC ACID is VERATRIC ACID.

VERINE *v.* VERATRUM ALKALOIDS.

VERNIN $C_{16}H_{20}N_8O_8$ 3aq. Occurs in young vetch plants (*Vicia sativa*), in young red clover (*Trifolium pratense*), in pumpkin seeds, in ergot, and in the blossom of *Corylus avellana* and *Pinus sylvestris* (E. Schulze, *J. pr.* [2] 32, 447; *H.* 10, 80, 326). Separated from asparagin by crystallisation from hot water. Minute silky prisms, v. sol. hot water, insol. alcohol. Its aqueous solution is neutral, gives no pp. with $Pb(OAc)_2$, but is ppd. by $AgNO_3$, by picric acid, and by phosphotungstic acid in presence of HCl. Boiling hydrochloric acid forms guanine.—$Ag_2C_{16}H_{18}N_8O_8$. Gelatinous pp.

VERNONIN $C_{10}H_{24}O_7$. Occurs in the root of *Vernonia nigritiana*, used on the west coast of Africa as a febrifuge (Heckel a. Schlagdenhauffen, *C. R.* 106, 1446). White powder, sl. sol. ether and chloroform, sol. alcohol. Conc. H_2SO_4 gives a brown colour, changing to purple. Cardiac poison, 80 pts. being required to produce the effect of 1 pt. of digitalin. Decomposed by boiling dilute HCl into glucose and a resin $C_4H_{10}O_2$.

VICIN $C_{28}H_{51}N_{11}O_{21}$. S. 1 at 23°. Occurs in the seeds of *Vicia sativa*, *V. Faba*, and *V. Faba minor* (Ritthausen, *J. pr.* [2] 2, 333; 24, 202; 29, 359). Obtained by extracting the seeds with cold dilute H_2SO_4 (1:50), neutralising with lime, filtering from $CaSO_4$, evaporating to dryness and crystallising from 85 p.c. alcohol. The yield is ·25 p.c.

Properties.—Tufts of small needles, nearly insol. alcohol. Loses $2H_2O$ at 160°. Sol. alkalis and alkaline earths, reppd. on neutralisation. Not affected by boiling baryta-water. Sol. dilute HCl and H_2SO_4, but after boiling the solution gives a deep-blue colour with $FeCl_3$ and NH_3, and a violet pp. with baryta. Boiling KOHAq (S.G. 1·1) also forms divicin. When evaporated with HNO_3 (S.G. 1·2) the residue is edged with deep violet. Potash-fusion forms KCy.

Salts.—$B'_4 4H_2SO_4$.—$B'_4 11HCl$. Slender needles.

Divicin $C_{21}H_{50}N_{20}O_{16}$. By boiling vicin with water (5 pts.) containing H_2SO_4 (1 pt.) at 0° there is formed crystalline $(C_{32}H_{28}N_{20}O_8)2\frac{1}{2}SO_4$, which yields divicin on treatment with exactly the calculated quantity of KOHAq. Flat prisms (from water). Reduces $AgNO_3$ at once. Not ppd. by baryta. A little $FeCl_3$ followed by NH_3 gives a splendid blue colour.—$B'8HNO_3$. Whetstone-shaped crystals, got by adding HNO_3 to a solution of divicin.

Convicin $C_{20}H_{28}N_6O_{11}$ 2aq. Obtained from powdered vetch seeds by extracting with alcohol, allowing vicin to crystallise from the extract, ppg. the mother-liquor with $HgCl_2$ and potash, decomposing the pp. with aqueous H_2S, and evaporating. The mixture of vicin and convicin so obtained is treated with dilute H_2SO_4, which dissolves the vicin only. Thin plates (from water), often resembling leucine. Hardly sol. cold water, sl. sol. alcohol. Not decomposed by boiling KOHAq (S.G. 1·1). Potash-fusion gives off NH_3, but forms no KCy. Insol. cold dilute HCl and H_2SO_4. Its aqueous solution gives a flocculent pp. with $Hg(NO_3)_2$.

VINACONIC ACID *v.* TRI-METHYLENE DI-CARBOXYLIC ACID.

VINCETOXIN $C_{10}H_{12}O_6$. [59°]. $[\alpha]_D = -50°$. Extracted by milk of lime from powdered asclepias root (Tanret, *C. R.* 100, 277; *Bl.* [2] 43, 620). Occurs in two forms, one soluble and one insoluble in water. Both forms are lævorotatory, amorphous, sl. alcohol, insol. ether. Boiling dilute HCl yields an amorphous, inactive sugar, which does not ferment with yeast.

VINYL ALCOHOL $CH_2:CH.OH$. This substance might be expected to be identical with aldehyde $CH_3.CHO$, but Poleck a. Thümmel (*B.* 22, 2863) suppose it to be present in ether that has been exposed to air and sunlight, and that its presence is indicated by the formation of a pp. $C_2H_3OHgOHg_2Cl_2$ when a solution of mercury oxychloride in Na_2CO_3Aq is added to commercial ether. This pp. is white, and is converted by boiling potash into explosive greenish-black 'acetylene mercury' $C_2H_2O_4Hg_4$, and by adding nitric acid to its alkaline solution into $C_2HHg_2OCl_2$, which is not explosive. H_2S passed into water containing the compound $C_2H_3O_2Hg_3Cl_2$ yields (γ)-tri-thio-acetic aldehyde [76°].

VINYL-DIACETONAMINE *v.* ACETONAMINES.

VINYL-AMINE $CH_2:CH.NH_2$. Formed by the action of moist Ag_2O or of KOHAq on bromo-ethylamine hydrobromide at 48° (Gabriel, *B.* 21, 1049, 2665). Known only in aqueous solution. Volatile with steam. Decomposes in aqueous solution even in the cold. SO_2 converts it into taurine.

Salts.—$^{\times}B'HCl$. Poisonous. Its aqueous solution is decomposed by heat.—$B'_2H_2PtCl_6$. Crystals, v. sol. water.—$B'_2 2BiI_3$. Minute scarlet hexagonal leaves.—$B'HAuCl_4$. Golden crystals.—$B'C_6H_3N_3O_7$. [142°]. Slender yellow needles.

Reference.—DI-IODOVINYLAMINE.

VINYL BROMIDE *v.* BROMO-ETHYLENE.

Vinyl tribromide *v.* TRI-BROMO-ETHANE.

VINYL CHLORIDE *v.* CHLORO-ETHYLENE.

VINYL ETHANE *v.* BUTYLENE.

VINYL-ETHYL-CARBINOL *v.* PENTENYL ALCOHOL.

VINYL-ETHYLENE *v.* BUTINENE.

VINYL ETHYL OXIDE $CH_2:CH.OEt$. (35·5° i.V.). S.G. $\frac{14\cdot5}{17\cdot5}$ ·7625. Formed by heating chloro-acetal $CH_2Cl.CH(OEt)_2$ with sodium at 140° (Wislicenus, *A.* 192, 106). Liquid, smelling like ether mixed with allyl compounds. Combines with Cl and Br, forming di-chloro- and di-bromo- di-ethyl oxide. A small quantity (1 g.) of iodine converts large quantities of the oxide (200 g.) into a viscid liquid. Dilute (1:4) H_2SO_4 forms aldehyde and $EtHSO_4$.

Reference.—CHLORO-VINYL-ETHYL OXIDE.

VINYL-ETHYL-PYRIDINE $C_5H_3NEt.CH:CH_2$. (98°–102° at 21 mm.). Formed by heating $C_5H_3NEt.CH_2.CH_2OH$ with conc. HCl at 170° (Prausnitz, *B.* 25, 2394). Oil, v. sol. ether.—$B'_2H_2Hg_5Cl_{12}$. Needles, sl. sol. hot water.

VINYL IODIDE *v.* IODO-ETHYLENE.

VINYL-MALONIC ACID *v.* TRIMETHYLENE DICARBOXYLIC ACID.

VINYL OXIDE $(C_2H_3)_2O$. (39°). Formed by the action of dry Ag_2O on vinyl sulphide (Semmler, *A.* 241, 90).

Reference.—HEXA-CHLORO-DI-VINYL OXIDE.

***o*-VINYL-PHENOL** $CH_2:CH.C_6H_4.OH$.

Methyl ether $CH_2:CH.C_6H_4.OMe$. *o-Vinyl-anisole.* (c. 198°). S.G. $\frac{15}{15}$ 1·0095, $\frac{30}{30}$ 1·0005. Formed from either of the methyl derivatives of *o*-oxy-phenyl-acrylic acid by successive treatment with HI and Na_2CO_3Aq (Perkin, *C. J.* 33, 211; 39, 429). Oil. Polymerises readily (at 150°), forming a glassy mass, which, however, on distillation, regenerates the original oil. It smells like high-boiling coal-tar naphtha. It forms a colourless compound with bromine. Forms a red solid with H_2SO_4.

***p*-Vinyl-phenol.** *Methyl ether* $CH_2:CH.C_6H_4OMe$. [3°]. (205°). S.G. $\frac{15}{15}$ 1·0029; $\frac{30}{30}$ ·9956. Formed by distilling methoxy-phenyl-acrylic acid (*q. v.*) and from the same acid by successive treatment with conc. HI (S.G. 1·94) and Na_2CO_3.

Reference.—BROMO- and NITRO- VINYL-PHENOL.

VINYL-PIPERIDINE $C_5H_{10}(C_2H_3)N$ (?). (147°). Formed by dehydration of oxy-ethyl-piperidine [32°] (Ladenburg, *B.* 22, 2587). Liquid, smelling like tropidine and coniine, v. sol. water.

Reference.—BROMO-VINYL-PIPERIDINE.

***p*-VINYL-ISOPROPYL-BENZENE** $C_{11}H_{14}$ *i.e.* $C_6H_4Pr.CH:CH_2$. (204°). S.G. $\frac{15}{4}$ ·8902. Formed by distilling cumyl-acrylic acid at 210° or by boiling α-bromo-β-cumyl-propionic acid with Na_2CO_3Aq (Perkin, *C. J.* 1877, ii. 660). Oil, smelling like cuminic aldehyde. Partially polymerises on boiling, and also on keeping, forming a glassy mass, reconverted into the original hydrocarbon by heat. Yields $C_{11}H_{14}Br_2$ [71°].

α-VINYL-PYRIDINE C_7H_7N *i.e.*

$$N\left\langle\begin{matrix}C(C_2H_3):CH\\CH\text{———}CH\end{matrix}\right\rangle CH$$

(159°). S.G. ^{0} ·9985. Formed by passing a mixture of pyridine and ethylene through a red-hot tube (Ladenburg, *B.* 20, 1643). Formed also by distilling oxy-ethyl-pyridine under high pressure or in presence of KOH (Ladenburg, *B.* 22, 2585), and by the action of NaOHAq on β-bromo-β-pyridyl-propionic acid (Einhorn, *A.* 265, 229). Liquid smelling like conyrine, m. sol. water, v. sol. alcohol. Decomposed by distillation under atmospheric pressure, but boils at 81° under 29 mm. Oxidised by $KMnO_4$ to picolinic acid, and reduced in alcoholic solution by Na to ethyl-pyridine.—**Salts:** $B'_2H_2PtCl_6$. [174°]. Crystals, m. sol. water.—$B'HAuCl_4$. [144°]. Yellow needles.

Tetra-vinyl-pyridine $C_5H(C_2H_3)_4N$. (277°). S.G. ^{0} 1·0515. Formed in the preparation of γ-ethyl-pyridine by heating pyridine ethylo-iodide in sealed tubes at 320° (Karan, *B.* 25, 2776). Sl. sol. water.—$B'_2H_2PtCl_6$. [175°].—$B'HAuCl_4$. [148°].—$B'HHgCl_3$. [146°]. Needles.

VINYL-QUINOLINE *v.* QUINOLYL-ETHYLENE.

VINYL SULPHIDE C_4H_6S *i.e.* $S(CH:CH_2)_2$. (101°). S.G. ·913. Constitutes the chief part of the essential oil of *Allium ursinum* (Semmler, *A.* 241, 90). Liquid, smelling like allyl sulphide.

Reactions.—1. Dry Ag_2O forms vinyl oxide.—2. Moist Ag_2O gives aldehyde.—3. Alcoholic $HgCl_2$ forms crystals of $C_8H_{12}Cl_4Hg_2S_2$, which, when heated with potassium sulphocyanide, yields vinyl sulphocyanide.—4. $PtCl_4$ added to its alcoholic solution ppts. $(C_2H_3)_6Cl_8Pt_2S_3$, which is decomposed by ammonium sulphide into vinyl chloride and dark-brown $(C_2H_3)_2PtS_3$.—5. $AgNO_3$ forms $(C_2H_3)_2SAgNO_3$.—6. Br gives $(C_2H_3Br_2)_2SBr_2$ [195°].—7. *Oxidising agents* yield CO_2, oxalic acid, and H_2SO_4 only.

VINYL-TOLUIDINE so called is DI-*p*-TOLYL-DI-ETHYLENE-DIAMINE.

VIOLAQUERCITRIN *v.* this vol. p. 373.

VIOLANTIN $C_8H_6N_6O_9$ 4aq. Formed by mixing hot conc. solutions of nitroso- and nitro-barbituric acids (violuric and dilituric acids). Formed also by warming hydurilic acid with dilute HNO_3 (Baeyer, *A.* 127, 223). Yellowish-white, crystalline powder, decomposed by water into its two component acids, but may be re-crystallised from HOAc or 50 p.c. alcohol. It is also split up into its components by salts of the stronger acids.

VIOLURIC ACID $C_4H_3N_3O_4$ *i.e.*

$$C_2O_2\left\langle\begin{matrix}NH\\NH\end{matrix}\right\rangle C:NOH.$$

Nitroso-barbituric acid. Mol. w. 157.

Formation.—1. From hydurilic acid by the action of nitric acid (S.G. 1·2) or nitrous acid (Baeyer, *A.* 127, 200).—2. By heating dilituric (nitro-barbituric) acid with glycerin.—3. By warming ferrous diliturate with KCy.—4. By boiling an aqueous solution of alloxantin with hydroxylamine hydrochloride (Pellizzari, *G.* 17, 258).—5. By adding hydroxylamine to an aqueous solution of alloxan (Ceresole, *B.* 16, 1133).—6. By adding KNO_2 to barbituric acid (Baeyer, *A.* 130, 140).

Properties.—Trimetric crystals (containing aq); $a:b:c$ = ·83:1:1·92. M. sol. cold water, sl. sol. alcohol. Its aqueous solution is ppd. by alcohol. $FeSO_4$ gives a deep indigo-blue colour. HNO_3 forms nitro-barbituric acid. Br forms di-bromo-barbituric acid and nitrous fumes. Reducing agents form uranil (amido-barbituric acid). Conc. HClAq forms hydroxylamine on heating.

Salts.—NH_4A'. Dark-blue prisms.—$KA'2aq$. Deep-blue crystals, v. sol. water, forming a blue solution; turned red by excess of KOH. A solution of the K salt in conc. HClAq deposits $(KA')_2(HCl)_3$ 6aq in colourless efflorescent prisms.—$BaA'_2 4aq$. Red dimetric tables, nearly insol. cold water.—MgA'_2 6aq. Purple-red crystals.—PbA'_2 4aq. Small red crystals.—AgA'.

Benzyl ether $CO<\begin{smallmatrix}NH.CO\\NH.CO\end{smallmatrix}>C:NOC_7H_7$. [226°]. Formed by the action of benzyl chloride on silver violurate (Conrad a. Guthzeit, *B.* 15, 2849). Silvery scales, sol. hot water and alcohol.

VIRIDIC ACID *v.* Caffetannic acid.

VIRIDINE $C_{12}H_{19}N$. (251°). S.G. 1·024. A homologue of pyridine occurring in coal-tar (Thenius, *C. C.* 1862, 53). Yellowish oil, with slight greenish fluorescence, sl. sol. water, v. sol. alcohol and ether.—$B'_2H_2PtCl_6$. Greenish brown, insol. water, alcohol, and ether. The mercuric chloride double salt melts at 85° and crystallises from water.

Isomeride $C_{12}H_{19}N$. (230°-235°). Obtained, with other bases, by heating methyl-ethyl-acroleïn with alcoholic ammonia (Hoppe-Seyler, *M.* 9, 651).—$B'HAuCl_4$. [93°].—$B'_2H_2PtCl_6$. [135°].

VISCIN $C_{10}H_{24}O_4$ (?). The glutinous constituent of the stalk, leaves, and berries of the mistletoe (*Viscum album*). Extracted from the bark by kneading with water, washing the sticky mass with 90 p.c. alcohol, and extracting the viscin with cold ether. The residue consists of viscaoutchin and woody-fibre (Reinsch, *C. C.* 1861, 145). Colourless, tasteless, semi-fluid mass, S.G. 1·0, decomposed by distillation, yielding oily viscene (226°) S.G. ·85, which forms a crystalline Na salt with conc. NaOHAq. Viscaoutchin is very glutinous. Its S.G. is ·978, and it is insol. alcohol and ether, sol. oil of turpentine.

VISCOSE is Dextrane (*q. v.*).

VITELLIN *v.* Proteïds.

VITELLOSE *v.* Proteïds.

VOLUMES, SPECIFIC; *v.* Specific volumes, p. 498.

VULPIC ACID $C_{19}H_{14}O_5$ *i.e.*

$$\begin{array}{l} \text{ÇPh:C(OH).Ç:CPh.CO}_2\text{Me} \\ \text{CO}\text{————}\text{O} \end{array}$$

Methyl pulvate. [148°]. Occurs in *Cetraria vulpina*, a lichen growing in Norway, and used there, mixed with nux vomica, as poison for wolves (Bebert, *A.* 2, 342; Strecker a. Möller, *A.* 113, 56; Spiegel, *B.* 13, 1629; 14, 1686; *A.* 219, 15). The lichen contains 2½ to 4 p.c. of the acid, which may be extracted by warm milk of lime. Vulpic acid is also formed by dissolving pulvic anhydride in a solution of KOH in MeOH. It appears to occur in the lichen *Parmelia parietina* (Berzelius; Stein, *J.* 1864, 553).

Properties.—Yellow plates or needles, sol. alcohol and ether, v. e. sol. chloroform, nearly insol. boiling water. Decomposed above 200° into MeOH and pulvic anhydride. Boiling milk of lime converts it into pulvic acid. Boiling KOHAq forms di-benzyl-glycollic acid and CO_2.

Salts.—NH_4A'. Yellow crystals, sol. water.—$BaA'_2 2aq$. Yellow needles (from water).—$BaA'_2 7aq$.—$KA'aq$. Light-yellow needles, sl. sol. water.—AgA'. Pp. Blackens at 190°.

Acetyl derivative $C_{19}H_{13}AcO_4$. [156°]. Colourless needles, insol. NaOHAq.

Methyl ether v. Di-methyl ether of Pulvic acid.

Isovulpic acid $C_{18}H_{11}MeO_5$. [124°]. Formed, in small quantity, together with pulvic anhydride, by heating vulpic acid at 200° (Spiegel). Thin golden plates (from alcohol). Forms orange solutions in alkalis.

W

WACKENRODER'S SOLUTION. The soluion obtained by passing H_2S for a long time into nearly saturated SO_2Aq. The solution conains $H_2S_3O_6$, much $H_2S_4O_6$, $H_2S_5O_6$, and probably $H_2S_6O_6$, along with H_2SO_4, dissolved colloidal S, and a little S in suspension; *v.* Thionic acids, p. 698.

WALDIVIN $C_{18}H_{24}O_{10}$. [230°]. S.G. 1·46. S. ·17 at 15°; 3 at 100°. S. (alcohol) ·53. Extracted by dilute alcohol from the powdered fruit of *Simaba waldivia* (Tanret, *Bl.* [2] 35, 104; *C. R.* 91, 886). Hexagonal prisms (containing 5aq), v. sol. chloroform, insol. ether. Neutral to litmus. Inactive to light. Tastes bitter.

WATER. H_2O. (*Hydrogen monoxide.*) Mol. w. 17·96. (For physical data *v. Properties.*)

Occurrence.—Pure water is never found in nature. The properties of different specimens of naturally occurring waters depend on the impurities they contain, and these impurities are derived from the substances with which the water has come into contact; hence it is customary to classify natural waters in accordance with their origin, as *rain-water*, *surface-water*, *well-water*, *mineral spring-water*, and *sea-water*. The composition of the substances found in these waters, and the properties of the waters themselves—that is, of the various more or less dilute aqueous solutions—are discussed in pp. 939-960 of vol. iv. of the Dictionary of Applied Chemistry. Solid water, more or less pure, is found as ice and snow. Water vapour is a constant constituent of the atmosphere. A great many minerals, and also many organic substances, contain water combined with other compounds.

Historical.—In 1781 Cavendish showed experimentally that water was the only product of burning H and O mixed in certain proportions, and that almost the whole of the H and O disappeared. The account of the experiments made by Cavendish was published in 1784 (*T.* 1784. 116).

‘When a mixture of inflammable and dephlogisticated air [*i.e.* in modern language, hydrogen and oxygen] is exploded in such proportions that the burnt air is not much phlogisticated, the condensed liquor contains a little acid, which is always of the nitrous kind . . .; but if the proportions be such that the burnt air is almost entirely phlogisticated, the condensed liquor is not at all acid, but seems pure water, without any addition whatever; and as, when they are mixed in that proportion, very little air remains after the explosion, almost the whole being condensed, it follows that almost the whole of the inflammable and dephlogisticated air is converted into pure water' (*l.c.* p. 133).

Translated into modern language, this statement would be taken as asserting that water is formed by exploding a mixture of H and O in proper proportions. It is, however, worthy of note that Cavendish did not himself interpret his experimental results as we interpret them to-day. He regarded 'dephlogisticated air' [oxygen] as 'nothing but dephlogisticated water, or water deprived of its phlogiston.' He said: 'We must allow . . . that inflammable air [hydrogen] is either pure phlogiston . . . or else water united to phlogiston' (*l.c.* pp. 137, 140).

The formation of water by burning H and O was thought of by Cavendish as the restoration of phlogiston to water that had been deprived of this principle. 'Water,' he said, 'consists of dephlogisticated air united to phlogiston.' Cavendish evidently thought of H and O as what we might now call *forms of water*; one of these was water with too little phlogiston, and the other was water with too much phlogiston; the explosion restored the phlogistic balance, and the properties of water were apparent. When Lavoisier had interpreted Cavendish's results, Cavendish spoke of Lavoisier's explanation as an hypothesis: 'According to this hypothesis we must suppose that water consists of inflammable air united to dephlogisticated air' (*l.c.* p. 150). Cavendish established the fact that water is the product of burning a mixture of H and O in the ratio (approximately) of 2 vols. H to 1 vol. O; but he stated this fact in language that no longer carries a definite meaning with it. Lavoisier added to the experimental basis whereon the fact rested, and he expressed the fact in language that still is clear, definite, and descriptive.

Formation.—1. By the direct union of H and O by igniting a mixture of these elements. 2. By deoxidising metallic oxides, and many other compounds that contain O, by heating with H.—3. By the decomposition of many compounds containing H and O, by heat, or by reactions with other substances.

According to Freyer a. V. Meyer (*B.* 25, 622), a mixture of H and O in the ratio 2H:O does not explode when slowly passed through a glass tube at 606°, and the temperature of ignition of the wet, gaseous mixture is between 650° and 730°. Askenasy a. V. Meyer (*A.* 269, 49) found that when pure, dry electrolytic gas was passed at a moderate rate through a glass tube heated to 518°, only c. ·7 to 1·7 mgms. of water were produced in ten hours; and that a little more water, but still only a very small quantity in proportion to the total quantity of H and O, was formed at 606°. Experiments made to determine the relation between the quantity of water formed and the time of the experiment showed that no constant relation could be arrived at, even when every precaution was taken to insure equality of conditions; the irregular action of the surfaces of the vessels was probably the cause of the irregularities in the results.

Davy (*T.* 1817) found that electrolytic gas did not explode when the pressure was so reduced that the gas was rarefied to $\frac{1}{16}$ of its ordinary density. Thomas (*C. J.* 35, 215) found that the gas exploded at 168 mm. pressure. L. Meyer a. Seubert (*C. J.* 45, 586) found that the sparks from a Ruhmkorff coil caused the combination of c. $\frac{3}{4}$ of a quantity of electrolytic gas at c. 70 mm. pressure, and that the remainder combined when the pressure was increased until it became the same as before the first explosion; this result is in keeping with Bunsen's determinations of the quantity of oxygen needed to prevent the explosion of 2H+O (*v.* M. a. S., *l.c.* p. 588). Dixon (*T.* 1884. 634) noticed that electrolytic gas did not explode at a pressure under 70 mm., but that explosion occurred under 75 mm. pressure (*cf.* D., *l.c.* p. 642).

According to the experiments of Dixon (*l.c.*), 'the union of oxygen and hydrogen is not affected by the presence or absence of water'; dry electrolytic gas exploded by the spark at a pressure between 70 mm. and 75 mm., and the wet gas exploded at the same pressure.

The velocity of explosion of electrolytic gas was found by Berthelot and Vieille (*C. R.* 95, 151) to be 2,810 metres per second (*cf.* EXPLOSION, vol. ii. p. 530).

Preparation.—Stas (*Chem. Proport.* 110) prepared pure water as follows. When large quantities were required, spring-water was *very slowly* distilled through a long copper tube, bent into zigzag form, completely filled with pure copper turnings that had been oxidised by strongly heating in O, the copper tube being surrounded by alumina and sand, and heated to full redness; the distillate was then distilled in an apparatus of platinum.

The second method recommended by Stas, especially when comparatively small quantities of pure water are required, is based upon destroying the organic matter in distilled water by the action of K manganate and permanganate. The process is described by Stas as follows:—

> I prepared potassium manganate by reacting on manganese oxide with caustic potash and potassium chlorate. I shook up the powdered product with water, just sufficient to dissolve the manganate that had been formed, and allowed the mixture to settle in a closed vessel. I then added 4 or 5 p.c. of the clear, dark-green solution to the spring water which was to be distilled, and allowed the components of this mixture to react for 24 hours. I then poured into the distillation vessel one or two litres of the conc. solution of potassium manganate that had been mixed with an equal volume of conc. caustic potash solution; this solution of potash was sufficiently conc. to make the salt so stable that its dilute solution could be heated for a long time without decomposition. I then filled the distillation vessel to c. $\frac{1}{10}$ with the water which had been in contact with the potassium manganate, and distilled in the ordinary way. When boiling began I moderated the heat, in order to prevent the liquid, which frothed much for some minutes, from passing over. When the frothing has stopped, the water may be boiled rapidly without the least inconvenience. When $\frac{1}{10}$ of the water has distilled over, that which then distils is completely free from organic substances, and also from mineral substances, if the upper part of the distillation vessel is furnished with diaphragms to hold back the extremely small drops that are always carried forward when a liquid is boiled vigorously.

Stas says that water thus prepared is perfectly free from organic matter. When he wished to obtain water absolutely free from any form of solid matter, Stas re-distilled the water that had been purified as described above, using as condenser a long tube of platinum soldered with gold. It is advisable to distil the water just before it is to be used.

On one occasion Stas used rain-water instead of well-water, and he found distinct quantities of ammonia in the distilled water thus prepared. To remove this he recommends to re-distil with $\frac{1}{1000}$ part of $NaHSO_4$ or $KHSO_4$.

Composition of water.—The gravimetric composition of water was determined by Berzelius a. Dulong (*A. Ch.* [2] 15, 86) and by Dumas (*A. Ch.* [3] 8, 189) by passing pure H over a weighed quantity of red-hot CuO, and weighing the water produced and the copper which remained. The results gave the ratio H:O = 1:8 (B. a. D.) and 1:7·98 (D.). An extended series of measurements by the same method, with many precautions, by Dittmar a. Henderson (*C. N.* 67, 127, 139, 151, 164 [1893]) gave the ratio H:O = 1:7·9327.

Several measurements have been made of the proportion by volume in which H and O combine to form water. Gay-Lussac in 1805, and Humboldt in 1805 (*A. Ch.* 53, 239), found the volumetric ratio of H:O to be 2:1. Morley, in 1891 (*Am. S.* [3] 41, 220, 276), determined the ratio of H:O to be 2·00023:1 by directly measuring the volumes of the gases. In 1892 Leduc (*C. R.* 116, 1248) found the ratio H:O = 2·0037:1, from determinations of the relative densities of H, O, and electrolytic gas. In 1893 Scott (*T.* 184, 543) completed a most carefully performed series of syntheses of water by sparking mixtures of H and O, and determined the most probable value of the volumetric ratio H:O to be 2·00245:1.

Properties.—Water is a clear, transparent, almost colourless, tasteless, odourless liquid. A column of water appears slightly blue when looked at lengthwise. Bunsen (*A.* 72, 44) pointed out that the slight blue colour of water may be observed by looking at a shining white object through a column of water 2 metres long, contained in a tube blackened inside. V. Meyer (*B.* 15, 297) recommends to join five wide, thin-walled glass tubes, c. 40 mm. internal diameter, and each c. 1½ metres long, by wide caoutchouc tubing, and thus to form a tube c. 7½ metres long; to lay the tube perfectly horizontal, and to close the end by smooth glass plates held in position by metallic clasps; then to cover the tube with black cloth. On looking through the tube the field of view appears quite colourless, but on now filling the tube with pure water (by means of brass tubes passing through the metallic clasps) a deep-blue colour is seen on looking through the column of water.

The *boiling-point* of water is 100° under the pressure of 760 mm. Zeuner (*Grundzüge der mechanischen Wärmetheorie*, Tab. 10 [1877]) gives the following table, showing the increase of boiling-point with increase of pressure:—

Pressure in atmos.	Boiling-point. °	Pressure in atmos.	Boiling-point. °
1	100	8	170·81
2	120·6	9	175·77
3	133·91	10	180·31
4	144	11	184·50
5	152·22	12	188·41
6	159·22	13	192·08
7	165·34	14	195·53

An elaborate table is given by Broch (*Trav. et Mém. du Bureau internat. des Poids et Mes.* 1, 46 [1881]) based on Regnault's determinations; the table gives the b.p. of water for each ·1 mm. from 680 to 800 mm. pressure. (The table is given in Landolt a. Börnstein's *Physikalisch-Chemische Tabellen* [Berlin, 1883], pp. 47–49.)

The *melting-point* of ice is slightly lowered by pressure. J. Thomson (*T. E.* 16) calculated that the m.p. would be lowered by *n* ·0075° for an increase of *n* atmospheres; W. Thomson (*P. M.* [3] 37, 123) confirmed this calculation by determining the m.p. of ice at 8·1 and 16·8 atmos. Mousson (*A. Ch.* [3] 56, 252) kept water liquid at −5° by greatly increasing pressure, and he found that at c. 13,000 atmos. pressure ice melted at −18°.

The *specific gravity* of water is greater at 4° than at any other temperature. Exner gives the temperature of maximum density as 3·945° (older determinations are tabulated by Exner, *W. A. B.* 68 (ii.), 463 [1873]). The following table, showing the density and volume of water from 0° to 100°, is given by Volkmann (*W.* 14, 260 [1881]); it is based on the determinations of Hagen, Matthiessen, Pierre, Kopp, and Jolly:

Temp. °	Density (*in vacuo*) i.e. wt. of 1 c.c. water in grams.	Volume of 1 gram water in c.c.
0	·999878	1·000122

100	·95856	1·04323

Rossetti (*P. Ergänsbd.* 5, 268 [1871]) gives he densities and volumes of water for each legree from −10° to 100°, referred both to water t 0° and to water at 4° as unity. The S.G. of ce is c. ·916 at 0° (water at 0° = 1); according o recent determinations by Zakrzevski (*W.* 47, 155 [1895]) the value is ·916660.

The *expansion* of water for various intervals f temperature has been measured by various bservers; putting $V_t = V_0\ (1 + at + bt^2 + ct^3)$, the ollowing values are given by Kopp (*P.* 72, 1 1847]; *cf.* Pierre, *P.* 86, 451; Weidner, *P.* 123, 300; Matthiessen, *P. M.* [4] 31, 149; Rossetti, *P. Ergänzbd.* 5, 258; Hirn, *A. Ch.* [4] 10, 32):

Temp.	*a*	*b*	*c*
0° to 25°	−·000061045	·0000077183	−·00000003734
25° to 50°	−·000065415	·0000077587	−·000000035408
50° to 75°	−·00005916	·0000031849	·0000000072848
75° to 100°	−·00008645	·0000031892	·0000000024487

For the expansion of water above 100° *v.* Mendeléeff (*A.* 119, 1).

As water freezes it expands by c. $\frac{1}{11}$ of its volume; one volume of water at 0° becoming 1·09082 volumes of ice at 0°. It expands when heated at temperatures below 0°; Zakrzevski (*W.* 47, 155) gives the co-efficient of expansion ·000077 (*v.* also Brunner, *P.* 64, 116; Struve, *P.* 66, 298; Marchand, *J. pr.* 35, 254).

The *compressibility* of water is small. Röntgen a. Schneider (*W.* 33, 644) give the absolute compressibility at 17·95° as ·0000462 per atmosphere of pressure (*v.* also Ramsay a. Young, *T.* 1892; and *cf.* Grassi, *A. Ch.* [3] 31, 437; and Rankine, *P. M.* [4] 1, 548; also Amaury a. Descamps, *C. R.* 68, 1564; and Cailletet, *C. R.* 75, 77).

A table showing the volume of 1 kilo. of *saturated water vapour* and the weight (in kilos.) of 1 c. metre of the vapour, at temperatures from 0° to 200°, is given by Zeuner (*v.* Landolt a. Börnstein's *Physikalisch-chemische Tabellen* [Berlin, 1883], p. 53; *cf.* Dieterici, *W.* 38, 1). According to Dieterici (*l.c.*) water vapour saturated at 0° behaves like a perfect gas.

The *vapour pressure* of water varies from 1·0288 mm. at −19° to 20926·4 mm. at 230°; for complete tables calculated from Regnault's determinations *v.* Landolt a. Börnstein's *Physikalisch-chemische Tabellen* [Berlin, 1883] pp. 40–46 (the vapour pressure is given for each 1° from −19° to 101°, and for each 1° from 101° to 230°). Ramsay a. Young (*T.* 1892) give a table of the vapour pressures of water up to 270°. In connection with the vapour pressures of water and ice, *v.* R. a. Y. (*T.* 1884. 470). For an expression representing the vapour pressure of water at any temperature up to 325°, *v.* Antoine (*C. R.* 113, 328).

The *spec. heat* of water increases as temperature rises; the quantity of heat required to raise 1 g. of water from $t°$ to $t° + 1$ is taken as unity in determinations of the spec. heats of other substances. The following table presents the data for S.H. of water at intervals of 10° from 0° to 230° (the memoirs by the different observers are: Regnault, *Acad.* 21, 729 [1847]; Jamin a. Amaury, *C. R.* 70, 661 [1870]; Bosscha, *P. Jubelbd.* 549 [1874]; von Münchhausen, *W.* 1,

592; 10, 284 [1877 and 1880]; Henrichsen, *W.* 8, 83 [1879]; Baumgartner, *W.* 8, 648 [1879]).

The following values for S.H. of water, from 0° to 35°, are given by Bartoli a. Stracciati (*A. Ch.* [6] 29, 285); the values in the column 'calculated' were obtained by using the formula:

$$\begin{aligned} \text{S.H.} = \; & 1{\cdot}006630 \\ & - {\cdot}000593962t \\ & + {\cdot}0000043838650t^2 \\ & + {\cdot}00000004255520t^3 \\ & - {\cdot}000000002819t^4 \end{aligned}$$

The unit is the quantity of heat given out by 1 gram water at 15° in cooling to 14°.

The S.H. of ice is considerably less than that of water; Regnault's determinations gave ·474 between −75° and 0°; the determinations of Person a. Desains gave ·504 between −20° and 0°; Ramsay a. Young (*T.* 1884. 475) give the value ·5 as the mean of various experiments. S.H. of water gas at 100° is given by Strecker (*W.* 17, 85) as ·37 referred to an equal weight of water = 1, and 1·36 referred to an equal volume of air = 1; the ratio $\frac{\text{S.H.p.}}{\text{S.H.v.}}$ given by S. is 1·4, Jaeger (*W.* 36, 165 [1889] gave the value 1·33 to this ratio, and Cohen (*W.* 37, 628 [1889]) gave the value 1·287 for the temperature interval 144° to 300°.

The *heat of vaporisation* of water—*i.e.* the quantity of heat required to convert 1 g. of water at 100° into steam at 100°—is 535·77 gram-units, according to Favre a. Silbermann (*A. Ch* [3] 37, 461). The following values are given for the heat required to convert 1 g. of water at t° completely into water vapour; 606·5 when $t=0°$, 637 when $t=100°$, 676·6 when $t=230°$ (Regnault, *Acad.* 21, 635); Dieterici (*W.* 38, 1) gives 596·8 when $t=0°$; Regnault (*l.c.*) gives the formula $\lambda = A + Bt$ for the total heat of vaporisation of water at different temperatures, and gives the values $A = 606{\cdot}5$, $B = {\cdot}305$.

According to Sakhrai (*C. J.* 61, 495 [1892]), 'the temperature of the steam escaping from a boiling salt solution is exactly the same as that of the solution.'

The *heat of fusion* of ice, *i.e.* the quantity of heat required to convert 1 g. of ice at t° into 1 g. of water at t° is given as follows by different observers (the values are in gram-units of heat):—79·24 and 79·06 when $t°=0$ (Regnault, *A. Ch.* [3] 8, 19); 79·25 when $t=0°$, 74·2 when $t=-10°$, 80·22 when t varies from −2° to −21° (Person, *A. Ch.* [3] 21, 295; 30, 73); 77·85 at −2·8°, 76·75 at −4·295°, 76·11 at −6·28°, 76·0 at −6·6° (Pettersson, *J. pr.* [2] 24, 129).

The *thermal conductivity* of water, from 10° to 18°, was determined by Winkelmann (*P.* 153, 481) to be ·154; Bottomley (*Pr.* 31, 300) obtained nearly the same value; this figure means that heat sufficient to raise ·154 mgm. water from 0° to 1° passes per second through a layer of water 1 mm. thick and 1 sq. mm. area, when the difference between the temperatures of the two surfaces of the layer is maintained at 1°. For *electrical conductivity* of water *v. Reactions*, No. 2.

The *refractive indices* of water at different temperatures, and for different lights of determinate wave-lengths, have been measured by many observers. The following values have been found for $\mu_{H\alpha}$: 1·33120 at 19·9°, 1·33091 at 23·7°, 1·33050 at 26° (Brühl, *B.* 24, 644). For detailed tabulation of the results obtained by Fraünhofer, van der Willingen, Baille, Damien, Landolt, Wüllner, and Rühlmann, *v.* Landolt a. Börnstein's *Physikalisch-Chemische Tabellen* [Berlin, 1883] 205; *cf.* also Perkin (*C. J.* 61, 293), who gives values for μ for the lines A C D and F, at 15° and 83·7°.

Observations have been made on the *absorption spectrum* of water and water-gas, but the matter has not been thoroughly investigated (*v.* Vogel, *P.* 156, 326; Jansen, *B. A.* 1866. 11).

Water crystallises, as ice, in rhombohedral forms; snow is generally found crystallised in six-sided stars derived from six-sided prisms.

Molecular weight of liquid water. Several observations have been made which tend to show that the molecular weight of liquid water is greater than 18. Paterno (*B.* 21, 3180), from measurements of the lowering of the freezing-point of water dissolved in acetic acid, concluded that the mol. w. might be 18, or might perhaps be 36. From the depression of the freezing-point of paratoluidine by water dissolved therein, Eykman (*Z. P. C.* 4, 510) concluded that the mol. w. of liquid water is probably 36, and this conclusion was strengthened by Walker's experiments on the connection between heats of fusion and solubility (*Z. P. C.* 5, 194). From measurements of the surface tension of water Ramsay and Shields (*C. J.* 63, 1089 [1893]) conclude that the mol. w. of liquid water is probably 72 at the ordinary temperature.

Reactions.—1. In 1847 Grove (*T.* 1847. 1) showed that water was decomposed into H and O by *heat.* Grove formed a little ball on the end of a Pt wire, by fusing the Pt, heated the globule of Pt to whiteness by an electric current, and plunged it into a little air-free water, nearly boiling, in a small basin, with a test tube full of air-free water arranged to collect any gas that might come off. Deville (*C. R.* 56, 195, 322 [1863]) found that H and O were given off in considerable quantities when molten Pt was plunged under water. D. noticed no decomposition when steam was passed through a Pt tube heated to bright redness, but by passing a current of an indifferent gas, such as CO_2, through the hot tube, and thus sweeping away the products of decomposition, H and O were obtained.—2. Water is scarcely decomposed by an *electric current.* Kohlrausch found the electrical conductivity of the purest water he could obtain by distillation *in vacuo* to be $2{\cdot}5 \times 10^{-6}$ in C.G.S. units, or c. 72 billionths of the conductivity of Hg (*P. M.* [5] 18, 542). By calculations based on this result, Ostwald concluded that in a litre of pure water the weight of water dissociated into H and OH ions, expressed in gram-molecules, is $\cdot 6 \times 10^{-6}$ (*Z. P. C.* 11, 521). By other methods of calculation, based on other data, Ostwald arrived at the value ·2 to $\cdot 9 \times 10^{-6}$ for what has been called the *dissociation constant* of water (*Z. P. C.* 11, 521); Wijs, by calculations based on the hydrolysis of methyl acetate, obtained the values $\cdot 1 \times 10^{-7}$ (*Z. P. C.* 11, 492), and $\cdot 14 \times 10^{-6}$ (*ibid.* 12, 514); Arrhenius obtained the value $\cdot 1125 \times 10^{-6}$ (*ibid.* 11, 827); and Bredig, the value $\cdot 6 \times 10^{-6}$ (*ibid.* 11, 829). Later experiments on the conductivity of water by Kohlrausch a. Heydweiller (*Z. P. C.* 14, 316 [1894]) with water that had been distilled *in vacuo* ten years ago, had then stood in a vessel filled with water, and been again distilled *in vacuo*, gave the following results:—conductivity (Hg = 1) ·014 at 0°, ·04 at 18°, ·058 at 25°, ·089 at 34°, ·176; all these to be multiplied by 10^{-10}. K. a. H. say that 1 mm. of this water at 0° had a resistance = that of 40 million kilometres of Cu wire of the same area. K. a. H. calculate that in 1 litre of the purest water at 18° there is ·00008 mgm. H as free ions, and ·000105 mgm. at 25°.—3. *Steam* is decomposed by *electric sparks*; for conditions and details of results *v.* Thomson (*Pr.* 53, 90).

The reactions of water are so many that an approximate classification of them into groups is all that can be attempted here.—4. Many *metals* react with water, at temperatures varying from the ordinary to a full red heat, forming oxides or hydroxides and giving off H. The following metals decompose cold water: Ba, Cs, Ca, (Ce ?), (La ?), Li, K, Rb, Na, Sr. Al, Fe, Pb, Mg, (? Mn), Mo, Ti react at c. 100°; and most of the other metals at temperatures from c. 100° to a full red heat.—5. Many *non-metals* react, generally slowly, with water, forming acids and giving off O. F rapidly decomposes water at the ordinary temperature; Cl reacts slowly at the ordinary temperature, and somewhat more rapidly at a red heat; Br reacts more slowly than Cl; I has probably a very slight (? any) action. S and P react slowly at 100°; Se is said not to decompose water at 160°. Carbon gives off H at a red heat. *Boron* acts like a metal, giving off H at a red heat.—6. Many *haloid compounds* react with water, giving oxyhaloid compounds or oxides, and haloid acids.—7. Some *metallic sulphides* react with steam to form oxides and H_2S. 8. A few of the *lower oxides* decompose water; *e.g.* $CrO.xH_2O$ at the ordinary temperature, and CO at c. 600°.—9. Water reacts with many *oxides* to form hydroxides which are either basic or acidic; in some cases hydrates are formed. Hydrates of various *salts* are also produced by combining the salts with water (*v.* Hydrates, vol. ii. p. 703; *cf.* Hydroxides, vol. ii. p. 733).—10. Water *dissolves* very many compounds of the most different properties (*v.* Solutions, vol. iv. p. 484).

Small quantities of water often bring about chemical changes that do not occur when the substances are perfectly dry; for instance, a mixture of dry CO and O is not exploded by sparks, but a trace of water suffices to start the change (*v.* Baker, *C. J.* 65, 611 [1894]).

The acidic and basic characters of water are so nearly balanced that the compound cannot be classed among either acids or basic bodies. The chemical relations of water to the compounds formed by reactions between it and other substances are determined chiefly by the chemical characters of the substances that react with it; thus the relations of HOH to $M_x(OH)_y$, formed by the interaction of water and metals, are those of an acid to its salts, whereas the relations of HOH to HX, formed by the interactions of water and non-metals, are those of a basic hydroxide to salts derived therefrom. The relations between both classes of derivatives of water and the parent compound are sometimes expressed by saying that the compounds belong to the *water type* (*v.* Types, vol. iv. p. 811). M. M. P. M.

WAX. A term applied to various natural solids more or less resembling bees'-wax. They are compound ethers, but differ from fats in yielding monovalent alcohols and not glycerin on saponification. They melt below 100°, are insol. water, sl. sol. or insol. alcohol, and sol. ether. They are not volatile.

Bees'-wax. [64°]. S.G. ·965. Consists of a portion (about 5 p.c.) soluble in alcohol (cerin) and a portion insoluble in alcohol (myricin). Myricin is myricyl palmitate (Brodie, *A.* 67, 180; 71, 144). Cerin is chiefly composed of cerotic acid; but it contains small quantities of melissic acid $C_{30}H_{60}O_2$ [90°], and an acid melting at 73° (Schalfejeff, *B.* 9, 278, 1688; Nafzger, *A.* 224, 246). There is also present one or more acids whose lead salts dissolve in ether and whose Ba salts dissolve in alcohol, and which therefore probably belong to the oleïc series. Myricin may be saponified by alcoholic potash, and the myricyl alcohol separated from potassium palmitate by extraction with ligroïn. Crude myricin yields CCl_4 and C_2Cl_6 when heated with I and excess of $SbCl_5$ at 400° (Hartmann, *B.* 24, 1022). Bees'-wax contains two hydrocarbons, one of which [60°] (c. 275° at 11 mm.) is probably *n*-heptaicosane $C_{27}H_{56}$, and the other [68°] (c. 360° at 11 mm.) *n*-hentriacontane $C_{31}H_{64}$ (Schwalb, *A.* 235, 106). According to Schwalb, the myricyl alcohol of bees'-wax has the formula $C_{31}H_{64}O$ [85°], and is converted by heating with soda-lime into an acid $C_{31}H_{62}O_2$ [89°], which forms a methyl ether [71°] and an ethyl ether [70°]. Among the products of saponification of bees'-wax, ceryl alcohol $C_{27}H_{56}O$ or $C_{26}H_{54}O$, and an alcohol $C_{25}H_{52}O$ or $C_{24}H_{50}O$ occur. The last-mentioned alcohol when heated with soda-lime gives an acid $C_{25}H_{50}O_2$ or $C_{24}H_{48}O_2$ [75·5°].

Carnaüba wax *v.* vol. i. p. 710.

Chinese wax, which is produced by an insect, is almost entirely composed of ceryl cerotate $(C_{27}H_{55})C_{27}H_{53}O_2$ (Brodie, *A.* 67, 199).

Cork wax *v.* Cerin.

Pine wax *v.* Ceropic acid.

Sugar-cane wax *v.* Cerosin.

Japan wax. [42°–55°]. Obtained in the East from *Rhus succedanea.* It appears to be really a fat, since palmitin is its chief component. It also contains the ether of a fatty acid of higher melting-point than stearic acid (Sthamer, *A.* 43, 343; Buri, *Ar. Ph.* [3] 14, 403).

Wax of Ficus gummiflua of Java contains an alcohol $C_{15}H_{30}O$ [73°], v. sol. ether, and a small quantity (5 p.c.) of isoceryl alcohol $C_{27}H_{56}O$, sl. sol. ether (Kessel, *B.* 11, 2112).

Myrtle wax. [49°]. Got by boiling the berries of *Myrica cerifera* of North America with water (Moore, *J.* 1862, 506). Consists of palmitic and some lauric acid and (20 p.c. of) palmitin.

Opium wax. Contains ceryl cerotate and ceryl palmitate (Hesse, *B.* 3, 637).

Tobacco wax. Contains $C_{70}H_{140}O_2$ [63°], insol. cold alcohol, sol. ether and a small quantity of $C_{60}H_{120}O_2$ [64·5°], sl. sol. cold ether (Kissling, *B.* 16, 2433).

Coca leaf wax (Hesse, *A.* 271, 214). The wax from Trujillo coca is palmityl-(β)-amyrin $C_{46}H_{80}O_2$ [75°] $[\alpha]_D = 54·5°$. On saponification it yields palmitic acid and (β)-amyrin $C_{30}H_{50}O$ [196°] $[\alpha]_D = 94·2°$, which yields an acetyl derivative [236°] and a benzoyl derivative [228°]. The wax from the broad-leaved coca of Peru and Bolivia melts at 70°; contains palmityl-(β)-amyrin and a ketone, (β)-cerotinone $C_{53}H_{106}O$ [66°], m. sol. alcohol, ether, and ligroïn. The wax from Java coca contains the same substances, and also some ceryl cerotate and ethers of myristic acid and of oxycerotic acid $C_{27}H_{54}O_3$ [82°], which is v. e. sol. hot alcohol and ligroïn, v. sl. sol. ether, and is converted by Ac_2O at 100° into cerotolic acid $C_{27}H_{52}O_2$ [70°].

WHEY-PROTEÏD *v.* Milk.

WINE OIL. *Light oil of wine.* An oil obtained in the preparation of ether by distilling alcohol with H_2SO_4. The ether is shaken with milk of lime and fractionally distilled, the successive fractions being ether, alcohol, and wet alcohol. Light oil of wine (·25 to ·5 p.c. of the alcohol etherified) rises to the surface when the last fraction (90°–120°) is allowed to stand. When dried over $CaCl_2$ it has S.G. $\frac{17·5}{}$ ·903. It contains $C_{10}H_{20}$ (157°), $EtOC_5H_{11}$ (112°), $Et.CO.C_5H_{11}$ (154°), and $CH_3.CO.C_6H_{13}$ (164°) (Hartwig, *J. pr.* [2] 23, 449).

Heavy oil of wine, which passes over when the temperature is raised after the preparation of ether, consists of Et_2SO_4 mixed with olefines (Claesson, *J. pr.* [2] 19, 259; Serullas, *A. Ch.* [2] 39, 152).

WINTERGREEN OIL contains methyl *o*-oxybenzoate.

WINTERENE $C_{15}H_{24}$. (260°–265°.) S.G. ·934. $[\alpha]_j$ 11·2° at 16°. A dextrorotatory sesquiterpene obtained by distilling winterbark (from *Drymis Winter-Forster*) with water (Arata a. Canzoneri, *G.* 18, 527). Coloured green by Br in $CHCl_3$.

WOOD *v.* Lignone.

WOOD GUM *v.* Xylan.

WOOD NAPHTHA *v.* Methyl alcohol.

√ **WOOD OIL.** *Gurjun Balsam.* Flows from incisions in the stem of *Dipterocarpus costatus.* It contains an essential oil, which gives a splendid violet colour when its solution in CS_2 (20 pts.) is treated with a drop of a cold mixture of HNO_3 and H_2SO_4. The same reaction is exhibited by the balsam itself, and also, in a more transient manner, by cod-liver oil and copaïba balsam (Flückiger, *Ph.* [3] 7, 2). The essential oil consists chiefly of a terpene (255°) (Werner, *J.* 1862, 461), which composes 65 p.c. of the balsam (Guibourt, *J.* 1876, 907). The resin contains a neutral substance, $C_{28}H_{46}O_2$, which crystallises from light petroleum in triclinic prisms [126°–130°]; it dissolves in conc. H_2SO_4, and is reppd. from the resulting reddish solution by adding water. It is not affected by potash-fusion (Flückiger, *Ar. Ph.* [3] 12, 58). A substance $C_{20}H_{30}O_2$ [129°] is described by Brix (*M.* 2, 516) as ppd. by adding water to an alcoholic extract of wood oil. It is neutral and insol. alkalis, and yields a diacetyl derivative [75°]. It is perhaps identical with the compound $C_{28}H_{46}O_2$. Wood oil also contains gurjunic acid $C_{22}H_{34}O_4$ [220°], which crystallises from alcohol, distils with decomposition at 260°, and forms Ag_2A''.

WOOD SPIRIT *v.* Methyl alcohol.

WORMSEED OIL. *Oleum Cinæ.* Obtained by steam-distillation from wormseed, the flower-buds of *Artemisia Vahliana, A. Sieberi,* and *A. inculta* (Trommsdorff, *Tr. N. J.* 3, 312; Völckel, *A.* 38, 110; 87, 312; Hirzel, *J.* 1854, 591; 1855, 655; Kraut a. Wahlforss, *A.* 128, 293; Faust a. Homeyer, *B.* 7, 1429; Hell a. Ritter, *B.* 17, 2609; Wallach a. Brass, *A.* 225, 291). It consists chiefly of cineol $C_{10}H_{18}O$. Wormseed (*A. Gallica*) also contains betaïne and choline (Jahns, *B.* 26, 1493).

WRIGHTINE $C_{11}H_{18}N$. [122°]. Occurs in the juice of *Wrightia antidysenterica* (Stenhouse, *Ph.* [2] 5, 493; Warnecke, *B.* 19, 60). Needles with bitter taste, sl. sol. water, v. sol. alcohol and ether. Cond. H_2SO_4 at 100° gives a dark-green colour, turned dark blue by adding water. Wrightine is probably identical with conessine (*q.v.*).

X

XANTHALINE $C_{37}H_{36}N_2O_9$. [206°]. Occurs in opium (T. a. H. Smith, *Ph.* [3] 23, 793). White crystalline powder, insol. water and alkalis, sl. sol. hot alcohol, m. sol. benzene, v. e. sol. chloroform. Weak base, forming yellow salts from which it is ppd. by hot water. Conc. H_2SO_4 forms a deep-orange solution, from which water ppts. the sulphate as yellow needles. Hot HNO_3 does not decompose it. Zinc and H_2SO_4 reduce it to hydroxanthaline $C_{37}H_{38}N_2O_9$, which forms white crystals [137°], nearly insol. water, v. sol. alcohol and benzene, and forms easily soluble crystalline salts. Hydroxanthaline is coloured deep-violet by H_2SO_4 (even free from HNO_3), the colour being destroyed by water, but reproduced by H_2SO_4.—$B'H_2Cl_2 4aq$: yellow needles. Gives off all its acid at 150°.

XANTHAMIDE *v. Ethyl ether* of (β)-THIOCARBAMIC ACID.

XANTHATES. The salts RS.CS.OEt where R is a metal; *v.* ETHYL DITHIOCARBONATE.

XANTHIC ACID *v.* ETHYL DITHIOCARBONATE.

XANTHINE $C_5H_4N_4O_2$ *i.e.*

$\left.\begin{array}{l}\mathrm{NH.CH{:}C.NH}\\ \mathrm{CO.NH.C{=}N}\end{array}\right\rangle\mathrm{CO}$. *Xanthic oxide.* Mol. w. 152. S. ·007 in the cold; ·08 at 100°. Occasionally found in urinary calculi (Marcet, *Essay on Calculi*, London, 1819; Liebig a. Wöhler, *A.* 26, 340; Lebon, *C. R.* 73, 47) and in urinary deposits (Bence Jones, *C. J.* 15, 78). Occurs in small quantity in the urine of man, in the pancreas, spleen, and liver of oxen, in the thymus gland of the calf, in muscle of mammalia and fishes (Scherer, *A.* 107, 314; 112, 257; Städeler, *A.* 111, 28; 116, 102; Dürr, *A.* 134, 45; Kossel, *H.* 6, 422), in some kinds of guano (Unger a. Phipson, *C. N.* 6, 16), and in yeast (Schindler, *H.* 13, 432). Occurs also in lupin seeds (Salomon, *J.* 1881, 1012; Schulze a. Barbieri, *J. pr.* [2] 27, 358), in pumpkin-seeds (E. Schulze, *J. pr.* [2] 32, 457), and in tea (Baginsky, *H.* 8, 396).

Formation.—1. By the action of nitrous acid on guanine (Strecker, *A.* 108, 141; 118, 151; 131, 121; Balke, *J. pr.* [2] 47, 542).—2. In small quantity by heating a mixture of HOAc and aqueous HCy (Gautier, *Bl.* [2] 42, 141).

Preparation.—1. Separates as a crystalline powder when $NaNO_2$ (8 g.) is added slowly to a solution of guanine (10 g.) in H_2SO_4 (20 g.) and water (150 g.) at 75° (Fischer, *A.* 215, 309).—2. The aqueous extract of sprouting lupin seeds is evaporated, the residue treated with alcohol, and the alcoholic filtrate evaporated. The residue is dissolved in water, and $AgNO_3$ and NH_3 added. The gelatinous pp. is dissolved in hot HNO_3 (S.G. 1·1), which yields on cooling a crystalline compound of hypoxanthine and silver nitrate, and on adding NH_3 to the filtrate silver-xanthine is ppd. (S. a. B.).—3. Urine is ppd. with baryta-water; the filtrate is evaporated to a small bulk and boiled with cupric acetate. The pp. is dissolved in warm nitric acid and ppd. with $AgNO_3$; the pp. is crystallised from hot diluted HNO_3, treated with ammoniacal $AgNO_3$, decomposed by H_2S, and the solution evaporated.—4. A solution containing xanthine is treated with Fehling's solution and hydroxylamine hydrochloride, and the ppd. copper compound decomposed by H_2S. The xanthine may be further purified by preparing its lead salt and decomposing this with H_2S (Balke, *J. pr.* [2] 47, 552).

Properties.—Small scales (by evaporation) or powder composed of minute globules, nearly insol. cold water, insol. alcohol and ether. V. e. sol. KOHAq and reppd. by CO_2 and other acids. Weak base. Does not form an acetate. A cold saturated aqueous solution of xanthine gives white pps. with $HgCl_2$ and $AgNO_3$, and a yellowish-green, flocculent pp. with hot cupric acetate. An ammoniacal solution of xanthine is ppd. by $HgCl_2$, $ZnCl_2$, $CdCl_2$, and $AgNO_3$. Xanthine reduces ammoniacal cupric chloride (Drechsel, *B.* 25, 2454). Xanthine evaporated with nitric acid leaves a yellow residue turned orange by KOH (but not by NH_3), the colour becoming violet-red on warming. Solid xanthine added to a mixture of bleaching-powder and NaOHAq on a watch-glass forms a dark-green spot, changing to brown and finally disappearing. Xanthine warmed with chlorine-water and a trace of HNO_3 as long as gases escape, and then evaporated to dryness, yields a residue which is coloured rose-red by gaseous NH_3 (Weidel, *A.* 158, 365; Kossel, *H.* 6, 426).

Reactions.—1. Decomposed above 150°, giving off HCy, NH_3, cyanogen, and CO_2.—2. $KClO_3$ and HClAq at 60° form urea and alloxan.—3. Conc. HClAq at 230° forms glycocoll, formic acid, NH_3, and CO_2 (E. Schmidt, *A.* 217, 311).—4. NaOH (2 mols.) and $Pb(OAc)_2$ form a lead salt which, if dried and heated with MeI at 130°, yields theobromine (Fischer).—5. Slowly attacked by pure HNO_3, the gas evolved consisting of nitrogen (1 vol.), CO_2 (4 vols.), and N_2O (11 vols.) (Franchimont, *R. T. C.* 6, 223).

Salts.—$B'HCl$. Nodular groups of silky needles.—$B'H_2SO_4$ aq. Scales, decomposed by water.—$B'BaH_2O_2$. Sl. sol. water.—$B'_2Cu_3O_2$. Formed by the action of Fehling's solution and hydroxylamine hydrochloride (Balke).—$B'Ag_2O$. Yellowish-white flocculent pp., got by adding $AgNO_3$ to an ammoniacal solution of xanthine. Blackens on boiling.—$NaC_5H_3N_4O_2$ aq. Minute needles.

Bromo-xanthine $C_5H_3BrN_4O_2$. Formed by heating xanthine with bromine at 100°, and also by the action of nitrous acid on bromoguanine (Fischer a. Reese, *A.* 221, 343). Crystalline powder, sol. conc. HClAq and H_2SO_4, but reppd. by water; sl. sol. hot water and hot alcohol; sol. alkalis.

Isoxanthine $C_5H_4N_4O_2$ *i.e.*

$\left.\begin{array}{l}\mathrm{NH.CO.C.NH}\\ \mathrm{CO.NH.C.CH}\end{array}\right\rangle\mathrm{N}$. Formed by reducing diazo-isonitroso-methyl-uracil $C_5H_5N_3O_3$ with $SnCl_2$ and HClAq (Behrend, *A.* 245, 223). Needles (containing ½aq); sl. sol. hot water. Dissolves in Ac_2O without change. On evaporation with HNO_3 it leaves a residue coloured orange by

KOHAq. Yields $C_5H_3BrN_4O_2$ aq, crystallising from water in six-sided tables.

Pseudo-xanthine $C_5H_4N_4O_2$. A product of the action of H_2SO_4 (2 pts.) on uric acid (1 pt.) at 120° (Schultzen a. Filehne, *B.* 1, 150). Formed also by the action of nitrous acid on adenine (Kossel, *H.* 10, 258). Powder, sl. sol. water, HClAq, and NH_3Aq, v. sol. KOHAq. Its aqueous solution is acid in reaction, and on evaporation with HNO_3 leaves a lemon-yellow residue, which is turned orange on warming with KOHAq.

The name **pseudo-xanthine** is also given by Gautier (*Bl.* [2] 48, 19) to a substance $C_4H_5N_5O$ occurring in muscular tissue. This is a yellow powder, which forms a very soluble hydrochloride. Its aqueous solution is ppd. by $HgCl_2$, $AgNO_3$, and ammoniacal $Pb(OAc)_2$, but not by $Pb(OAc)_2$. This pseudo-xanthine also gives an orange colour when the residue, after evaporation with HNO_3, is treated with potash.

Paraxanthine $C_7H_8N_4O_2$. [c. 284°]. Occurs in human urine (Salomon, *B.* 16, 195; 18, 3406; *H.* 13, 187; Thudichum, *H.* 11, 415; Kossel, *H.* 13, 302). Silky needles or monoclinic tables, insol. alcohol and ether, sl. sol. cold water, v. sol. hot water. Sol. NH_3Aq and HClAq. Poisonous, acting like caffeïne and theobromine. $AgNO_3$ added to its solution in HNO_3 or NH_3Aq gives a gelatinous or flocculent pp. Picric acid forms a yellow crystalline pp. when added to its solution in HClAq. Gives a red colour (like xanthine) when the residue after evaporation with chlorine-water is exposed to gaseous NH_3. Does not give an orange colour when KOHAq is added to the residue after evaporation with HNO_3. Conc. NaOHAq forms a crystalline salt. KOHAq does the same. A solution of paraxanthine is ppd. by $Cu(OAc)_2$, phosphotungstic acid, $HgCl_2$, and ammoniacal lead subacetate, but not by mercuric nitrate.

Heteroxanthine $C_6H_6N_4O_2$. Occurs in urine of men and dogs (Salomon, *B.* 18, 3407; *H.* 11, 412). Amorphous powder, v. sl. sol. cold water, sol. NH_3Aq, insol. alcohol and ether. Its solution in HClAq is not ppd. by picric acid. $AgNO_3$, $HgCl_2$, $Cu(OAc)_2$, and ammoniacal lead subacetate give pps. When evaporated with chlorine-water and HNO_3 it leaves a residue which is coloured red by gaseous NH_3, the colour changing to blue on addition of NaOHAq. NaOHAq forms a salt crystallising in tables, v. sol. water, sl. sol. NaOHAq. The hydrochloride forms sparingly soluble crystalline aggregates, which lose HCl on treatment with water.

Hypoxanthine *v.* vol. ii. p. 745.

XANTHININE $C_4H_5N_3O_2$. S. ·0025 in the cold; ·025 at 100°. Formed by heating ammonium thionurate at 200° (Finck, *A.* 132, 298). Got also by heating pseudo-uric acid with H_2SO_4 at 150° (Grimaux, *Bl.* [2] 31, 535). White powder, nearly insol. water, sol. NH_3Aq, forming a solution with blue fluorescence. Its solution gives a white pp. with $HgCl_2$ and a yellow pp. with $AgNO_3$. Not attacked by HNO_3. Sol. KOHAq and reppd. by CO_2. Sol. conc. H_2SO_4, forming a laminar sulphate, decomposed by water with separation of xanthinine.—$B'Ag_2O$. Bulky yellow pp., got by pouring an ammoniacal solution of xanthinine into excess of aqueous $AgNO_3$.

XANTHOCHELIDONIC ACID *v.* CHELIDONIC ACID.

XANTHOCREATININE *v.* CREATININE and LEUCOMAÏNES.

XANTHOGALLOL $C_{18}H_4Br_{14}O_6$ *i.e.*

$C_6H_2Br_4O\!\left\langle\begin{array}{l}O\cdot C_6HBr_3O\\O\cdot C_6HBr_3O\end{array}\right\rangle\!O$ (?). [122°]. Formed by adding pyrogallol (1 pt.) to bromine (10 pts.), leaving the mixture to stand for two hours, and then shaking with water and heating (Stenhouse a. Groves, *C. J.* 28, 1; *A.* 177, 191; 179, 237; Theurer, *A.* 245, 334). Tri-bromo-pyrogallol is an intermediate body in its preparation. Yellow laminæ (from CS_2 and ligroïn), v. sol. ether and CS_2, m. sol. ligroïn. Decomposed by boiling with water or alcohol. Very stable towards oxidising agents, even crystallising unaltered from conc. HNO_3. Not reduced by sodium-amalgam or by zinc and dilute H_2SO_4. Aniline in HOAc yields an anilide [205°], to which Theurer assigns the impossible formula $C_{18}H_4Br_{11}(NHPh)_4O_6$. *p*-Toluidine forms a corresponding *p*-toluide. Reacts with phenyl-hydrazine acetate.

Reactions.—1. NaOHAq forms hexa-bromo-benzene dihydride $C_6H_2Br_6$ [139°], sl. sol. alcohol, which crystallises in prisms, while the mother-liquor contains a sodium salt of an acid $C_5H_4Br_2O_3$ [124°], which forms BaA″, crystallising from dilute alcohol in large white plates (Theurer). By the action of dilute NaOHAq on xanthogallol, Hantzsch a. Schniter (*B.* 20, 2033) obtained $C_{18}H_4Br_{11}(OH)_3O_6$, which yields $Ba_3(C_{18}H_4Br_{11}O_9)_2$ and crystalline $C_{18}H_4Br_{11}Ac_3O_6$.—2. Na_2CO_3Aq converts xanthogallol in the cold into $C_{18}H_7Br_{11}O_9$, crystallising from benzene in needles [72°] and prisms [131°], yielding the crystalline derivatives $C_{18}H_7Br_{11}O_6 3NPhH_2$ and $C_{18}H_7Br_{11}O_6 3NH_2.C_6H_4Me$.—3. HBr passed into a cooled solution of xanthogallol in MeOH forms $C_{18}H_4Br_{11}O_3(OMe)_6$, crystallising from MeOH in prisms [113°], and converted by boiling dilute NaOHAq into an acid $C_6H_2Br_4O_2(OMe)_2$ [105°], and by MeOH and hydrochloric acid into $C_6HBr_4Cl(OMe)_4$ [77°]. The brominated acid $C_6H_2Br_4O_2(OMe)_2$ reacts with aniline, forming crystalline $C_6H_2Br_4O_2(OMe)_2NH_2Ph$. Conc. H_2SO_4 converts $C_6H_2Br_4O_2(OMe)_2$ into $C_6H_2Br_4O_3$ [65°].—4. Hydrochloric acid gas passed into a cooled solution of xanthogallol in MeOH forms $C_{18}H_4Br_{11}Cl_3O_3(OMe)_6$ [86°], which is insol. water, v. sol. alcohol, does not react with aniline, and is decomposed by dilute alkalis.—5. HCl passed into an alcoholic solution of xanthogallol forms $C_{18}H_4Br_{11}Cl_3O_3(OEt)_6$, crystallising from alcohol in colourless prisms [75°], converted by NaOHAq into a product [92°]. $C_{18}H_4Br_{11}Cl_3O_6$ [104°] is a bye-product in the action of alcohol and HCl on xanthogallol. It forms large yellow crystals, v. sol. alcohol.

XANTHOGENIC ACID *v.* ETHYL DITHIOCARBONATE.

XANTHOMETHYLIC ACID *v.* METHYL THIOCARBONATES.

XANTHONE is DIPHENYLENE KETONE OXIDE.

XANTHOPURPURIN is *m*-DI-OXY-ANTHRAQUINONE.

XANTHOQUINIC ACID *v.* OXY-QUINOLINE CARBOXYLIC ACID.

XANTHORHAMNIN $C_{48}H_{66}O_{29}$ (?). Obtained from Persian berries (the fruit of *Rhamnus infectoria*) by extracting with three times their weight of 85 p.c. alcohol; the yield being 12 p.c. (Liebermann a. Hörmann, *B.* 11, 952, 1618; *A.* 196, 307; *cf.* Kane, *P. M.* [3] 23, 3; Gellatly, *N. E. P. J.* 7, 252; *C. N.* 3, 196; Hlasiwetz, *A.* 111, 108; Bolley, *A.* 115, 55; *U. J.* 13, 328; Stein, *Z.* [2] 5, 183, 568; Behrend, *B.* 11, 1353). Yellow needles (containing 2aq), v. sol. water and alcohol, insol. ether. Has little tinctorial power. Reduces Fehling's solution and ammoniacal $AgNO_3$, forming a mirror. $FeCl_3$ gives a dark-brown pp. Ppd. by ammoniacal lead acetate. Boiling dilute H_2SO_4 splits it up into rhamnetin (2 mols.) and isodulcite (4 mols.).

Salts.—$C_{48}H_{62}K_4O_{29}$. Yellow powder, v. e. sol. water.—Pb_2A^{iv}. Yellow pp.

Acetyl derivatives $C_{48}H_{54}Ac_{12}O_{29}$ (Schützenberger, *Z.* [2] 4, 668).—$C_{48}H_{49}Ac_{17}O_{29}$. Powder, v. e. sol. alcohol (Liebermann a. Bergami, *B.* 20, 2245).

XANTHOROCCELIN *v.* PICRO-ROCCELIN.

XANTHORRHŒA RESIN is ACAROID RESIN.

XANTHOXYLIN $C_{10}H_{12}O_4$. [80°]. Occurs, together with xanthoxylene $C_{10}H_{16}$ (162°) in the essential oil from japan-pepper (*Xanthoxylon piperitum*) (Stenhouse, *Ph.* [2] 13, 423; 17, 19; *A.* 104, 237). Silky monoclinic crystals, insol. water, v. sol. alcohol and ether. Its alcoholic solution is not ppd. by $AgNO_3$ or lead acetate, even on addition of NH_3Aq.

XENYLAMINE *v. p*-AMIDO-DIPHENYL.

XENYLENE-DIAMINE *v. p-p*-DI-AMIDO-DIPHENYL.

XERONIC ACID *v.* DI-ETHYL-MALEÏC ACID.

XYLAN $C_6H_{10}O_5$. *Tree gum. Wood gum.* S. 2 at 100°. $[\alpha]_D = -69{\cdot}6°$ (Tollens); $-84°$ (Thomsen). Obtained from the bark of trees (T. Thomsen, *J. pr.* [2] 19, 146; Poumarède a. Figuier, *A.* 64, 388). Obtained, to the extent of 1·73 p.c., by extracting jute with dilute (5 p.c.) NaOHAq; and got also by extracting beech-wood or pine-wood sawdust with 5 p.c. NaOHAq (Tollens, *A.* 254, 307, 320, 324, 326; *Bl.* [3] 1, 1102; Winterstein, *H.* 17, 381). Obtained also by extracting wheat-straw, first with 2 p.c. NH_3Aq, and then with 5 p.c. NaOHAq (Tollens, *A.* 260, 291). The alkaline extract is ppd. with alcohol and HCl.

Properties.—Porous mass, insol. cold, sol. hot, water; sol. NaOHAq. The hot aqueous solution becomes opalescent on cooling. Insol. alcohol, but the aqueous solution is not ppd. by alcohol unless an acid or the salt of an alkali is added. Insol. NH_3Aq, lime- and baryta-water. Its aqueous solution is lævorotatory. Gives furfuraldehyde when distilled with H_2SO_4 or HCl, and xylose when boiled with dilute H_2SO_4. Gives no colour with iodine. HNO_3 oxidises xylan to saccharic acid, but gives no mucic acid.

***o*-XYLENE** C_8H_{10} *i.e.* $C_6H_4Me_2$ [1:2]. *Di-methyl-benzene.* Mol. w. 106. [−28°] (Colson, *A. Ch.* [6] 6, 128). (142°). S.G. $\frac{0}{0}$ ·8932 (Pinette, *A.* 243, 50); ^{21} ·876 (Gladstone, *C. J.* 59, 290). μ_A 1·4928, μ_H 1·5328. C.E. (0°–10°) ·00098. S.V. 139·9 (Schiff); 137·6 (Pinette). H.C. 1,084,274 [$C,O_2 = 94{,}000$; $H_2,O = 69{,}000$] (Stohmann, *J. pr.* [2] 35, 41). M.M. 13·31 (Schönrock, *Z. P. C.* 11, 758. *Critical temperature*: 358° (Altschul, *Z. P. C.* 11, 590). Occurs in coal-tar. The S.G. of crude xylene varies between ·857 and ·866; it contains 70 to 87 p.c. *m*-xylene, 3 to 10 p.c. *p*-xylene, 2 to 15 p.c. *o*-xylene, and 3 to 10 p.c. fatty hydrocarbons (Levinstein, *B.* 17, 444; *cf.* Fittig, *A.* 148, 10). If 100 c.c. of the mixture are boiled for 45 minutes with 40 c.c. of HNO_3 (S.G. 1·42) diluted with 60 c.c. of water, the *p*- and *o*-xylene are oxidised, leaving the *m*-xylene and fatty hydrocarbons. If the residual hydrocarbons, after washing with NaOHAq followed by steam distillation, be shaken for 30 minutes with 1½ volumes of H_2SO_4, the *m*-xylene will be sulphonated and dissolved, while the fatty hydrocarbons remain. If 100 c.c. of crude xylene be shaken with 120 c.c. of H_2SO_4, the *o*- and *m*-xylene dissolve, leaving the *p*-xylene and fatty hydrocarbons. On crystallising the sodium salts of the dissolved sulphonic acids, sodium *o*-xylene sulphonate separates first, and may be converted into *o*-xylene by heating in a sealed tube with HClAq at 190° (Jacobsen, *B.* 10, 1009), or by heating with diluted sulphuric acid. Nölting, Witt, and Forel (*B.* 18, 2668) found 25 p.c. of *p*-xylene in commercial xylene. According to Nölting and Palmer (*B.* 24, 1955), crude xylene may contain 10 p.c. of ethyl-benzene. When a mixture of *o*-xylene and ethyl-benzene is treated with Br (20 pts.) and I, tetra-bromo-xylene is formed, together with a less highly brominated ethyl-benzene (Crafts, *C. R.* 114, 1110).

Formation.—1. By distilling its carboxylic acids with lime.—2. From *o*-bromo-toluene, MeI, and Na (Jannasch a. Hübner, *A.* 170, 117; Reymann, *Bl.* [2] 26, 532).—3. By heating cantharidin with P_2S_5 (Piccard, *B.* 12, 580).—4. By passing MeI through a mixture of toluene and $AlCl_3$ at 85° (Jacobsen, *B.* 14, 2628).

Properties.—Oil, solidifying in a freezing-mixture at −28°. Unlike *m*- and *p*- xylene it does not yield a solid nitro- derivative with a cold mixture of H_2SO_4 and HNO_3. It is completely oxidised by chromic acid mixture.

Reactions.—1. Dilute HNO_3 forms *o*-toluic acid.—2. Boiling aqueous $KMnO_4$ oxidises it to phthalic acid.—3. PCl_5 at 200° reacts, forming $C_6H_4(CCl_3).CHCl_2$ (Colson a. Gautier, *Bl.* [2] 45, 507).—4. *Bromine* in the dark forms bromo-*o*-xylene $C_6H_3Me_2Br$ [1:2:4]. In direct sunshine the products are $C_6H_4Me.CH_2Br$ and $C_6H_4(CH_2Br)_2$ (Schramm, *B.* 18, 1278).—5. $AlCl_3$ and gaseous HCl at 100° yield benzene, *m*- and a little *p*-xylene, ψ-cumene and mesitylene (Hesse a. Töhl, *A.* 270, 168).

***m*-Xylene** $C_6H_4Me_2$ [1:3]. V.D. 3·68 (calc. 3·67) (Schiff, *A.* 220, 92). (139°). S.G. $\frac{0}{0}$ ·8812 (Pinette, *A.* 243, 50); $\frac{12\cdot8}{4}$ ·8715 (S.); $\frac{20}{4}$ ·8655 (Brühl, *A.* 235, 13); $^{22\cdot5}$ ·864 (Gladstone, *C. J.* 59, 290). C.E. (0°–10°) ·00096. μ_α 1·495 (B.); μ_A 1·4876, μ_H 1·5277. S.V. 139·8. H.C. 1,084,168 (Stohmann, *J. pr.* [2] 35, 41). M.M. 12·73 at 20°–30° (Schönrock, *Z. P. C.* 11, 758). *Critical temperature*: 346° (A.). Occurs in coal-tar (*v. o*-XYLENE).

Formation.—1. From *m*-iodo-toluene, MeI, and Na (Wroblewsky, *A.* 192, 200).—2. From (1,3,4)-xylidine and amyl nitrite (Staedel a. Holz, *B.* 18, 2919).—3. From toluene, MeCl, and $AlCl_3$ (Friedel a. Crafts, *A. Ch.* [6] 1, 461; Ador a. Rilliet, *B.* 11, 1627).—4. By distilling mesitylenic and xylylic acids with lime (Fittig, *A.* 148, 10; 156, 236).

Properties.—Liquid. Not attacked by dilute HNO_3. Conc. HNO_3 on warming forms tri-nitro-xylene [176°], sl. sol. alcohol.

Reactions.—1. Oxidised by *chromic acid mixture* to isophthalic acid.—2. PCl_5 at 200° forms a hexachloride (Colson a. Gautier, *Bl.* [2] 45, 508).—3. *Bromine* in the dark forms $C_6H_3Me_2Br$ [1:3:4], while in direct sunshine $C_6H_4Me(CH_2Br)$ and $C_6H_4(CH_2Br)_2$ are produced (Schramm, *B.* 18, 1277; *M.* 8, 305).—4. $AlCl_3$ and gaseous HCl at 100° form benzene, mesitylene, and some *p*-xylene and ψ-cumene (Heise a. Töhl, *A.* 270, 168). On boiling with $AlCl_3$ the products are benzene, toluene, a little *p*-xylene, ψ-cumene, mesitylene, and durene (Anschütz, *A.* 235, 182).—5. On heating with MeI and I at 250° it yields ψ-cumene, mesitylene, and $C_{10}H_{14}$ (Rayman a. Preis, *A.* 223, 320).—6. *Ethyl-malonyl chloride* at 60° in presence of $AlCl_3$ forms the ketone $C_{13}H_{14}O_2$ [63°] (Béhal a. Auger, *Bl.* [3] 3, 122).—7. *Benzoyl peroxide* forms dixylylene $C_{16}H_{18}$ (265°), S.G. $\frac{22}{}$ ·9984 (Lippmann, *M.* 7, 528).—8. CrO_2Cl_2 added to its solution in CS_2 ppts. chocolate brown $C_6H_4Me_2 2CrO_2Cl_2$, which is converted by water into *m*-toluic aldehyde and at 200° yields $C_6H_4Me.CH(CrO_2Cl)_2$ (Étard, *A. Ch.* [5] 22, 244).—9. CH_2Cl_2 and $AlCl_3$ form tetra-methyl-anthracene [163°] (Friedel a. Crafts, *A. Ch.* [6] 11, 268).—10. PH_4I forms C_8H_{14} on heating (Baeyer, *Z.* [2] 4, 455). HIAq and P at 280° form *m*-xylene hexahydride.

***p*-Xylene** $C_6H_4Me_2$ [1:4]. [13°] (Reissert, *B.* 23, 2242); [15°] (Jannasch). (138°). S.G. $\frac{0}{0}$ ·8801 (R.); $\frac{23\cdot7}{}$ ·860 (Gladstone, *C. J.* 59, 290). C.E. (0°–10°) ·00098 (Pinette, *A.* 243, 51). μ_A 1·4854. μ_H 1·5253. S.V. 140 (Schiff). H.C. 1,084,274 (Stohmann, *J. pr.* [2] 35, 41). M.M. 12·79 at 20°–30° (Schönrock, *Z. P. C.* 11, 753). *Critical temperature*: 344°. Occurs in coal-tar (*v. supra*) and in Galician petroleum (Pawlewski, *B.* 18, 1915). Formed by the action of MeI and sodium on *p*-bromo-toluene (Fittig, *A.* 136, 303; Jannasch, *A.* 171, 79) and on *p*-di-bromo-benzene (V. Meyer, *B.* 3, 753). Monoclinic prisms; $a:b:c = 2\cdot32:1:2\cdot34$; $\beta = 69\cdot5°$ (Baeyer, *A.* 245, 141).

Reactions.—1. Dilute HNO_3 forms *p*-toluic acid.—2. *Chromic acid mixture* yields terephthalic acid.—3. PCl_5 at 190° gives $C_6H_4(CH_2Cl)_2$ and at 200° $C_6H_4(CCl_3)_2$ (Colson a. Gautier, *Bl.* [2] 45, 6, 507).—4. *Bromine* in the dark forms $C_6H_3BrMe_2$, while in direct sunshine the products are $C_6H_4Me.CH_2Br$ and $C_6H_4(CH_2Br)_2$ (Schramm, *B.* 18, 1276).—5. $AlCl_3$ and HCl at 100° act in the same way as with o-xylene.

References.—Bromo-, Bromo-nitro-, Chloro-, Dichloro-nitro, Di-iodo-, Nitro-, and Oxy-xylenes.

XYLENE-AZO- compounds *v.* Azo- compounds.

XYLENE CARBOXYLIC ACID *v.* Di-methyl-benzoic acid and Mesitylenic acid.

***m*-XYLENE DICARBOXYLIC ACID** $C_{10}H_{10}O_4$ *i.e.* $C_6H_2Me_2(CO_2H)_2$ [1:3:4:6]. *Dimethyl-iso-phthalic acid.*

(α)-*Cumidic acid.* Mol. w. 194. [above 320°]. Formed by heating di-bromo-*m*-xylene dissolved in ether under pressure with $ClCO_2Et$ and sodium-amalgam. Formed also, together with (β)-cumidic acid, by oxidation of durene with dilute HNO_3 or of durylic acid with $KMnO_4$ (Schnapauff, *B.* 19, 2508). Minute prisms (from water) or plates (by sublimation).—BaA″ 1½aq: crystals, v. sol. water. Yields *m*-xylene on distilling with lime.

Methyl ether Me_2A''. [76°]. Crystals.

***m*-Xylene dicarboxylic acid** $C_6H_2Me_2(CO_2H)_2$ [1:3:4:5]. *Dimethyl-phthalic acid. Isocumidic acid.* [280°]. Formed by oxidation of (β)- and (γ)-isodurylic acid (Jacobsen, *B.* 15, 1857). Small crystals. May be sublimed. Yields *m*-xylene on distillation with lime. The Ca salt crystallises in small plates. The Ba salt is amorphous.

***p*-Xylene dicarboxylic acid** $C_6H_2Me_2(CO_2H)_2$ [1:4:2:5]. *Di-methyl-terephthalic acid.* (β)-*Cumidic acid.* Formed, together with (α)-cumidic acid, by oxidation of *s*-durene with dilute HNO_3 or of durylic acid with $KMnO_4$ (S.). Minute six-sided prisms (from alcohol). Sublimes in small plates without melting. Nearly insol. hot water. Yields *p*-xylene on distilling with lime.—BaA″ 2½aq: tables, v. sol. water.

Methyl ether Me_2A''. [114°]. (c. 297° cor.).

Xylene dicarboxylic acid $C_6H_3Me(CO_2H)CH_2.CO_2H$ [3:2:1]. [178°]. Formed by oxidation of $C_6H_3Me(CO.Et)CH_2.CO_2H$ (Béhal a. Auger, *C. R.* 109, 972). Gives off CO_2 on fusion.

Xylene di-ω-carboxylic acid *v.* Phenylene-diacetic acid.

Reference.—Oxy-xylene carboxylic acid.

XYLENE GLYCOL *v.* Di-oxy-xylene.

***o*-XYLENE DIHYDRIDE** *v.* Cantharene.

***m*-Xylene dihydride** C_8H_{12}. (133°). S.G. $\frac{22}{}$ ·828. V.D. 3·74 (calc. 3·88). μ_D 1·4675. Formed, together with a polymeride $C_{16}H_{24}$ (280°–285°) S.G. $\frac{20}{}$ ·832, by heating the ketone $C_8H_{14}O$ with $ZnCl_2$. The ketone itself is obtained by distilling the anhydride $C_{10}H_{14}O_4$ which is got by the action of Ac_2O on cineolic acid, formed by oxidation of eucalyptol (Wallach, *A.* 258, 327). Liquid, smelling like xylene. Yields on nitration $C_6H_3Me_2(NO_2)$ [1:3:4].

***p*-Xylene dihydride**

$CMe\langle{}^{CH.CH_2}_{CH_2.CH}\rangle CMe$. (134°) at 720 mm. Formed by heating di-methyl-quinite dibromide $C_8H_{14}Br_2$ with quinoline (Baeyer, *B.* 25, 2122). Smells like turpentine. Forms a crystalline compound with HBr.

***m*-Xylene tetrahydride** $C_6H_8Me_2$. (119°). S.G. $\frac{0}{}$ ·814; $\frac{14}{}$ ·794.

Formation.—1. By heating oxycamphoric anhydride $C_{10}H_{14}O_4$ with water at 180° or with HI at 150° (Wreden, *A.* 163, 336).—2. By heating camphoric acid with syrupy phosphoric acid at 200°.—3. By distilling camphoric acid with $ZnCl_2$ (Ballo, *A.* 197, 322).—4 By heating camphoric acid with HIAq at 200° (Wreden, *A.* 187, 171).

Properties.—Oil. Oxidised by chromic acid mixture to acetic, *m*-toluic, isophthalic, and terephthalic acids. HNO_3 forms tri-nitro-*m*-xylene.

Xylene tetrahydride C_8H_{14}. (131°). S.G. $\frac{22}{}$ ·816. Occurs among the products of the distillation of colophony (Renard, *A. Ch.* [6] 1, 236). Slightly dextrorotatory liquid. Yields oily di- and tri- bromo- derivatives. Sulphuric acid forms an oily polymeride $C_{16}H_{28}$, which is oxidised by fuming HNO_3 to succinic and oxalic acids. Absorbs oxygen. Does not reduce ammoniacal $AgNO_3$. In ethereal solution it combines with Br, forming $C_8H_{14}Br_2$.

m-Xylene tetrahydride (?) C_8H_{14}. (120°). *Octonaphthylene.* Formed by the action of moist Ag_2O on $C_8H_{15}I$, which is got by the action of CaI_2 at 60° on $C_8H_{15}Cl$ (175°), a product of the chlorination of octonaphthene (Jakowkin, *J. R.* 16, ii. 294). Oil, smelling like turpentine. Combines with Br (2 atoms). An isomeric octonaphthylene (123°–129°) is got by distilling $C_8H_{15}Cl$ obtained by chlorination of iso-octonaphthene (Putochin, *J. R.* 16, ii. 295).

m-Xylene hexahydride C_8H_{16} *i.e.* $C_6H_{10}Me_2$ [1:3]. *Octonaphthene.* (118°). S.G. $\frac{0}{0}$ ·7814 (Lossen, *A.* 225, 110); $\frac{20}{0}$ ·7706 (A.). C.E. (0°–26°) ·001072. V.D. 3·87. S.V. 164·8. $\mu_D = 1·419$ at 22° (Wallach, *B.* 25, 923). Occurs in Baku petroleum (Beilstein a. Kurbatoff, *B.* 13, 1820; Markownikoff a. Spady, *B.* 20, 1850), and among the products of the distillation of colophony (Renard, *A. Ch.* [6] 1, 229). Formed by heating heptanaphthene carboxylic acid with HIAq and P (Aschan, *B.* 24, 2718). Prepared by heating camphoric acid or *m*-xylene with HIAq at 200° (Wreden, *A.* 187, 157). Liquid. Not oxidised by aqueous $KMnO_4$. H_2SO_4 and HNO_3 form tri-nitro-*m*-xylene. Sulphur at 220° forms *m*-xylene.

Isomeride C_8H_{16}. *Iso-octonaphthene.* (122°). S.G. $\frac{0}{0}$ ·7767 $\frac{17.5}{0}$ ·7637. Occurs in Caucasian petroleum (Putochin, *J. R.* 16, ii. 295). Liquid.

p-Xylene hexahydride $C_6H_{10}Me_2$[1:4]. (138° cor.). V.D. 4·01 (obs.). S.G. $\frac{4}{4}$ ·7956. Formed by heating bromo-camphor with $ZnCl_2$ (R. Schiff, *B.* 13, 1407; *G.* 10, 320). Liquid, yielding tri-nitro-*p*-xylene [137°] on nitration.

m-XYLENE PHOSPHINIC ACID

Chloride $C_6H_3Me_2.PCl_2$ [1:3:4]. (257°). Got from mercuric dixylyl $Hg(C_6H_3Me_2\ [4:1:3])_2$ and PCl_3 at 235° (Weller, *B.* 20, 1720). Liquid, converted by water into the acid $C_6H_3Me_2P(OH)_2$. Chlorine forms the compound $C_6H_3Me_2.PCl_4$, which is converted by water into $C_6H_3Me_2PO(OH)_2$ [194°].

m-Xylene-phosphinic acid $C_6H_3Me_2P(OH)_2$ [98°] (Michaelis, *A.* 212, 237). Formed by the action of water on the chloride. Needles (from alcohol). Probably a mixture.

Chloride $C_6H_3Me_2.PCl_2$ (256°). S.G. ^{12} 1·24. Formed from *m*-xylene, PCl_3, and $AlCl_3$ (Weller, *B.* 20, 1720). It is a mixture of the preceding body and the 1,3,5 isomeride. Readily absorbs chlorine, forming $C_6H_3Me_2PCl_4$, whence SO_2 forms $C_6H_3Me_2.POCl_2$ (280°–300°).

p-Xylene phosphinic acid $C_6H_3Me_2P(OH)_2$. *p-Xylene phosphinous acid.* Formed by treating the chloride with hot water (Weller, *B.* 21, 1494). Crystallises with difficulty.

Chloride $C_6H_3Me_2PCl_2$. [–30°]. (254°). S.G. $\frac{15}{15}$ 1·25. Formed by heating *p*-xylene (150 g.) with $AlCl_3$ (30 g.) and PCl_3 (200 g.) for 36 hours with inverted condenser (Michaelis a. Paneck, *A.* 212, 236). Strongly refracting liquid.

m-XYLENE *s*-PHOSPHONIC ACID $C_6H_3Me_2PO(OH)_2$. *m-Xylene (α)-phosphinic acid.* [194°]. S. 1·5 at 20°; 6·9 at 100°. Formed by boiling the chloride $C_6H_3Me_2PCl_4$ (*v. supra*) with water (Weller, *B.* 20, 1721). Needles, v. e. sol. alcohol. Decomposed into *m*-xylene and phosphoric acid on heating with alkalis. Br added to dilute solutions forms bromo- and di-bromo-*m*-xylene. Yields two nitro- derivatives [182°] and [100°].

Salts. — BaA″aq. Plates. — $CdH_2A''_2$aq. Plates, more sol. cold than hot water. — $NiH_2A''_2$aq.—Ag_2A'': white pp.

m-Xylene *s*-phosphonic acid $C_6H_3Me_2.PO(OH)_2$. *m-Xylene (β)-phosphinic acid.* [161°]. S. 1·8 at 15°; 117·3 at 100°. Prepared by boiling with water the mixture of chlorides $C_6H_3Me_2.POCl_2$ (280°–300°) which is got by the action of SO_2 on the mixture of tetrachlorides $C_6H_3Me_2.PCl_4$ formed by combination of chlorine with the mixture of chlorides $C_6H_3Me_2PCl_2$ obtained by heating *m*-xylene with PCl_3 and $AlCl_3$ (W.). Plates or needles, v. e. sol. alcohol and ether. Decomposed by alkalis into *m*-xylene and phosphoric acid.

p-Xylene phosphonic acid $C_6H_3Me_2.PO(OH)_2$. [180°]. Formed by the action of water on $C_6H_3Me_2.PCl_4$ [c. 60°] which is got by passing Cl through the product of the action of PCl_3 on *p*-xylene in presence of $AlCl_3$ (Weller, *B.* 21, 1494). Needles, m. sol. water, v. sol. alcohol, sl. sol. ether. Conc. HNO_3 forms the compound $C_6H_2(NO_2)Me_2PO(OH)_2$ [224°]. $KMnO_4$ yields $C_6H_3Me(CO_2H).PO_3H_2$ [278°].

Salts.—KHA″.—BaA″. Pearly plates, more sol. cold than hot water.

Chloride $C_6H_3Me_2.POCl_2$. (281°). S.G. $\frac{18}{18}$ 1·31. Oil. Formed by the action of SO_2 on $C_6H_3Me_2.PCl_4$.

Reference.—Nitro-xylene phosphonic acid.

XYLENE PHTHALOYLIC ACID *v.* Phenyl xylyl ketone carboxylic acid.

o-XYLENE SULPHINIC ACID $C_8H_{10}SO_2$ *i.e.* $C_6H_3Me_2.SO_2H$ [1:2:4]. [83°]. Formed by the action of zinc-dust on *o*-xylene sulphochloride (Jacobsen, *B.* 10, 1011). Plates (from water).

m-Xylene sulphinic acid $C_6H_3Me_2(SO_2H)$ [1:3:4]. [c. 50°]. Formed by reducing the sulphonic chloride $C_6H_3Me_2.SO_2Cl$ (Jacobsen; *cf.* Lindoff a. Otto, *A.* 146, 233). Crystalline.

p-Xylene sulphinic acid $C_6H_3Me_2(SO_2H)$ [1:4:2]. [85°]. Groups of needles (Jacobsen, *B.* 11, 22).

o-XYLENE SULPHONIC ACID $C_8H_{10}SO_3$ *i.e.* $C_6H_3Me_2(SO_3H)$ [1:2:4]. Formed by warming *o*-xylene with H_2SO_4 (Jacobsen, *B.* 10, 1011; 11, 22). Tables (containing 2aq) (from dilute H_2SO_4).—NaA′ 5aq.—BaA'_2 2aq. S. 5·8 at 0°; 33·6 at 100°.

Chloride $C_6H_3Me_2.SO_2Cl$. [52°]. Prisms.

Amide $C_6H_3Me_2.SO_2NH_2$. [144°]. Yields two acids $C_6H_3Me(CO_2H).SO_2NH_2$ on oxidation by $KMnO_4$.

o-Xylene *c*-sulphonic acid $C_6H_3Me_2.SO_3H$ [1:2:3]. Formed by the action of sodium-amalgam on $C_6H_2Me_2Cl(SO_3H)$ [1:2:6:3] (Krüger, *B.* 18, 1760).

Amide $C_6H_3Me_2.SO_2NH_2$. Granules.

m-Xylene *c*-sulphonic acid $C_6H_3Me_2(SO_3H)$ [1:3:2]. *m-Xylene (β)-sulphonic acid.* Formed, together with a larger quantity of the (1,3,4)-isomeride, by dissolving *m*-xylene in fuming H_2SO_4 (Jacobsen, *A.* 184, 188; *B.* 11, 18). It remains in the acid liquor after pp. the (1,3,4)-isomeride by the proper quantity of water. Potash-fusion yields *p*-xylenol [74·5°] (Jacobsen, *B.* 21, 2828). Its K salt heated with sodium formate forms an acid $C_9H_{10}O_2$ [99°].—KA'.—BaA'$_2$: minute needles.—CuA'$_2$aq.

Chloride $C_6H_3Me_2.SO_2Cl$. Oil.

Amide $C_6H_3Me_2.SO_2NH_2$. [96°]. Needles.

***m*-Xylene sulphonic acid** $C_6H_3Me_2(SO_3H)$ [1:3:4]. *m-Xylene (a)-sulphonic acid.* Formed as above. Long flat prisms (containing 2aq). Its K salt heated with sodium formate yields xylylic acid.—NaA'.—BaA'$_2$. Small plates.—ZnA'$_2$ 9aq.—CuA'$_2$ 6aq.

Chloride $C_6H_3Me_2.SO_2Cl$. [34°].

Amide [137°]. Needles (from water). BzCl at 160° forms $C_6H_3Me_2.SO_2NHBz$ [151°] Mahon, *Am.* 4, 194), which yields crystalline Ba$(C_{15}H_{14}NSO_3)_2$aq and BaA'$_2$, sl. sol. water.

***p*-Xylene sulphonic acid** $C_6H_3Me_2(SO_3H)$ [1:4:2]. Formed by sulphonating *p*-xylene (Beilstein a. Wahlforss, *A.* 133, 38; Fittig a. Glinzer, *A.* 136, 305; Jacobsen, *B.* 10, 1009; 11, 22; Remsen a. Emerson, *Am.* 8, 265). Plates or prisms (containing 2aq). Oxidised by alkaline KMnO$_4$ to sulpho-terephthalic and two sulpho-*p*-toluic acids.—NaA'aq. [148°]. Trimetric plates; *a*:*b*:*c* = 1·077:1:1·498 (Moody a. Nicholson, *C. J.* 57, 978).—KA'aq.—BaA'$_2$. S. 2·27 at 0°; 5·53 at 100°.—CuA'$_2$ 8aq. Light-blue triclinic prisms.—ZnA'$_2$ 10aq.

Chloride $C_6H_3Me_2.SO_2Cl$. [26°]. Prisms.

Amide [148°]. Needles, m. sol. hot water.

***o*-Xylene disulphonic acid** $C_6H_2Me_2(SO_3H)_2$. Formed by heating (1,2,4)-xylene sulphonic acid with ClSO$_3$H at 150° (Pfannenstill, *J. pr.* [2] 46, 155).—K$_2$A''aq.—BaA''3aq.—PbA''3aq. Prisms.

Chloride $C_6H_2Me_2(SO_2Cl)_2$. [79°]. Prisms.

Amide $C_6H_2Me_2(SO_2NH_2)_2$. [239°].

***m*-Xylene disulphonic acid** $C_6H_2Me_2(SO_3H)_2$ [1:3:4:2]. Formed by heating *m*-xylene with fuming H$_2$SO$_4$ at 150° (Wischin, *B.* 23, 2113), and by heating (1,3,4)-xylene sulphonic acid with SO$_3$ at 150° (P.). Deliquescent needles, converted by potash-fusion into $C_6H_2Me_2(OH)_2$ [146°].—(NH$_4$)$_2$A''.—NaHA'' 3aq.—K$_2$A'' 2aq.—BaA''3aq. Needles, v. sol. water.—PbA'' 3aq.—CuA''. Gummy mass.

Ethyl ether Et$_2$A''. Plates.

Chloride $C_6H_2Me_2(SO_2Cl)_2$. [129°]. Converted by PCl$_5$ at 180° (2,4,1,3)-di-chloro-xylene (220°).

Amide $C_8H_{12}N_2S_2O_4$ [249°]. Needles. Oxidised by KMnO$_4$ to $C_6H_2\left(\left\langle{}^{CO}_{SO}\right\rangle NH\right)_2$ [225°].

Ethylamide $C_6H_2Me_2(SO_2NHEt)_2$. [135°].

***m*-Xylene disulphonic acid** $C_6H_2Me_2(SO_3H)_2$ [1:3:2:6?]. Formed in small quantity, together with the preceding isomeride, by heating (1,3,2)-xylene sulphonic acid with ClSO$_3$H at 150° (Pfannenstill, *J. pr.* [2] 46, 154). Needles.

Chloride $C_6H_2Me_2(SO_2Cl)_2$. Oil.

Amide. [210°]. More sol. water than its isomeride.

***p*-Xylene disulphonic acid** $C_6H_2Me_2(SO_3H)_2$ [1:4:2:6?]. Formed by heating (1,4,2) $C_6H_3Me_2(SO_2Cl)$ with fuming H$_2$SO$_4$ (Holmes, *Am.* 13, 372; Pfannenstill, *J. pr.* [2] 46, 156). Needles, v. e. sol. water.—BaA'' 3aq.—CaA'' 4aq.—MgA'' 7aq.—PbA'' 3aq.—Ag$_2$A''aq.

Chloride $C_6H_2Me_2(SO_2Cl)_2$. [75°].

Amide $C_6H_2Me_2(SO_2NH_2)_2$. [295°].

References.—BROMO-, BROMO-NITRO-, NITRO-, and NITRO-AMIDO-, XYLENE SULPHONIC ACID.

XYLENE THIOSULPHONIC ACID. *Xylyl ether* $C_8H_9.SO_2S.C_8H_9$. *Xylyl disulphoxide.* Formed by heating xylene sulphinic acid with water at 150°–160° (Otto a. Lindoff, *A.* 146, 239). Oil, v. sol. alcohol and ether.

XYLENIC ALCOHOL is TOLYL-CARBINOL.

XYLENIC DIBROMIDE *v.* DI-ω-BROMO-XYLENE.

XYLENIC GLYCOL *v.* DI-ω-OXY-XYLENE.

***o*-XYLENOL** $C_8H_{10}O$ *i.e.* $C_6H_3Me_2.OH$ [1:2:4]. Mol. w. 122. [62°]. (225° i.V.). H.F.p. 61,566 (Stohmann, *J. pr.* [2] 34, 316). Obtained by potash-fusion from the sulphonic acid (Jacobsen, *B.* 11, 28), and by the diazo-reaction from (1,2,4)-xylidine (Jacobsen, *B.* 17, 161). Long needles (from water). SiCl$_4$ yields Si(OC$_8$H$_9$)$_4$, crystallising in prisms (350°–360° at 120 mm.) (Hertkorn, *B.* 18, 1691). Ammoniacal ZnBr$_2$ at 300° from xylidine and dixylylamine.—NaOC$_8$H$_9$. Flat needles, v. sl. sol. NaOHAq.

Benzoyl derivative [57°]. H.F. 77,768 (Stohmann, *J. pr.* [2] 36, 8).

***o*-Xylenol** $C_6H_3Me_2(OH)$ [1:2:3]. [75°]. (218° i.V.). Occurs in coal-tar (Schulze, *B.* 20, 410). Formed by the action of nitrous acid on *c-o*-xylidine (Töhl, *B.* 18, 2562; Nölting a. Forel, *B.* 18, 2673). Slender needles. Its aqueous solution gives a blue colour with FeCl$_3$.

***c-m*-Xylenol** $C_6H_3Me_2(OH)$ [1:3:2]. [49°]. Obtained from the crude xylidine, or by the action of HCl on *p*-oxy-mesitylenic acid (Nölting; Jacobsen, *B.* 21, 2829). *p*-Xylenol is got instead of *m*-xylenol by potash-fusion from (1,3,2)-xylene sulphonic acid (Jacobsen, *B.* 11, 26; 21, 2828).

***m*-Xylenol** $C_6H_3Me_2(OH)$ [1:3:4]. [26°] (Jacobsen, *B.* 18, 3463); [[illegible]8°] (Staedel a. Hölz, *B.* 18, 2919). (211·5° i.V.). S.G. $\frac{0}{4}$ 1·0362. H.F.p. 59,501 (Stohmann, *J. pr.* [2] 34, 316).

Formation.—1. From *m*-xylene sulphonic acid by potash-fusion (Jacobsen, *B.* 11, 24, 375; *cf.* Wroblewsky, *Bl.* [2] 10, 286; Wurtz, *J.* 1868, 459).—2. By heating oxy-mesitylenic acid with conc. HClAq at 200° (Jacobsen, *B.* 11, 2052).—3. By reduction of nitro-*m*-xylene and treatment of the resulting xylidine with nitrous acid (Harmsen, *B.* 13, 1558; S. a. S.; Hodgkinson a. Limpach, *C. J.* 63, 104).

Properties.—Needles, v. sl. sol. water, miscible with alcohol and ether. Volatile with steam. FeCl$_3$ colours its aqueous solution blue and its alcoholic solution green, being changed to bright blue on dilution with water. Yields the corresponding xylidine and di-xylyl-amine when heated with ZnBr$_2$, ammonia, and NH$_4$Br at 315° (Müller, *B.* 20, 1041). Potash-fusion forms (4,1,3)-oxy-toluic acid. Yields oily PO(OC$_8$H$_9$)$_3$ (Kreysler, *B.* 18, 1703). SiCl$_4$ forms Si(OC$_8$H$_9$)$_4$ (455°) (Hertkorn, *B.* 18, 1690).

Salt.—NaOC$_8$H$_9$. V. sol. water and conc. NaOHAq (unlike Na salts of other xylenols).

Methyl ether MeOC$_8$H$_9$ (192° i.V.) (J.); (186°) (S.). H.F.p. 46,336 (Stohmann, *J. pr.* [2] 35, 24).

Acetyl derivative C$_8$H$_9$OAc. (226° i.V.).

***s*-Xylenol** $C_6H_3Me_2(OH)$ [1:3:5]. [64°] (T.); [68°] (N. a. F.) (220°). Occurs in coal-tar (Schulze, *B.* 20, 410). Formed by the action of nitrous acid on *s*-xylidine (Thöl, *B.* 18, 362; Nölting a. Forel, *B.* 18, 2679). Slender needles (from water). Not coloured by $FeCl_3$.—$NaOC_8H_9$. Plates, sl. sol. NaOHAq.

p-**Xylenol** $C_6H_3Me_2(OH)$ [1:4:2]. [74·5°]. (211·5° i.V.). H.F.p. 61,362 (Stohmann, *J. pr.* [2] 34, 316). S.G. ^{21} ·971. Formed by potash-fusion from *m*- and from *p*-xylene sulphonic acid and from oxy-mesitylenic acid (Wurtz, *A.* 147, 378; Jacobsen, *B.* 11, 26). Formed also from *p*-xylidine by diazotisation followed by boiling with water (Nölting, Witt, a. Forel, *B.* 18, 2665). Long flat needles (from dilute alcohol). Volatile with steam. Its aqueous solution is not coloured by $FeCl_3$.

Potash-fusion gives (3,4,1)-oxy-toluic and oxy-terephthalic acids. KNO_2 and HOAc yield a nitroso- derivative $C_6H_2Me_2(OH)(NO)$[1:4:3:6] [163°], which is the oxim of *p*-xyloquinone (Oliveri, *G.* 12, 162; Goldschmidt a. Schmid, *B.* 18, 568).

Salt.—$NaOC_8H_9$. Large plates, sl. sol. cold NaOHAq.

Methyl ether $MeOC_8H_9$. (194° i.V.). Oil.

Ethyl ether $EtOC_8H_9$. (199°) (S.); (205°) (N. W. a. F.). Oil. H.F.p. 54,150.

Acetyl derivative C_8H_9OAc. (237° i.V.). S.G. $\frac{15}{4}$ 1·0264. Oil, not solid at −20°.

Xylenol. (220°). Occurs in beechwood-tar (Marasse, *A.* 152, 75; Tiemann a. Mendelssohn, *B.* 10, 57). Oil. Yields C_8H_9OMe (220°). On boiling with aqueous $KMnO_4$ it yields an acid which is converted by potash-fusion into *u*-oxy-isophthalic acid [300°].

References.—BROMO- and NITRO- XYLENOLS.

XYLENOLIC ACID *v.* OXY-DI-METHYL-BENZOIC ACID.

o-**XYLENOL SULPHONIC ACID** $C_8H_{10}SO_4$ *i.e.* $C_6H_2Me_2(OH).SO_3H$. Formed by sulphonation of (1,2,4)-xylenol (Jacobsen, *B.* 11, 24). $FeCl_3$ gives a violet colour in neutral solutions.—NaA′. Slender prisms or small laminæ.—BaA'_2. Nodular groups of minute laminæ, sl. sol. cold water.

m-**Xylenol (α)-sulphonic acid.** Formed, together with the (β)-isomeride, by dissolving (1,3,4)-xylenol in H_2SO_4 (J.). $FeCl_3$ gives a violet-blue colour.—NaA′. Tables.—KA′. Plates.—BaA'_2. Leaflets.

m-**Xylenol (β)-sulphonic acid**
$C_6H_2Me_2(OH).SO_3H$ [1:3:4:2] (Jacobsen, *A.* 195, 283). Formed as above. Coloured violet-blue by $FeCl_3$. Converted by potash-fusion into (2,5,1)-oxy-toluic acid. — NaA′ 4aq. Laminæ. —BaA'_2. Minute needles, less soluble than the Ba salt of the (α)-acid. By sulphonating (1,3,4)-xylenol by $ClSO_3H$, Hodgkinson (*C. J.* 63, 110) obtained a xylenol sulphonic acid yielding BaA'_2aq.

m-**Xylenol sulphonic acid**
$C_6H_2Me_2(OH).SO_3H$ [1:3:6:4]. Formed from $C_6H_2Me_2(NH_2).SO_3H$ by the diazo-reaction (Sartig, *A.* 230, 336). Slender needles, v. sol. water and alcohol. The acid and its salts give with $FeCl_3$ a bluish-violet colour turned green by alcohol.—KA′.—BaA'_2 aq. Needles, v. e. sol. water.—PbA'_2 2aq.

Ethyl derivative $C_6H_2Me_2(OEt).SO_3H$. Formed by heating diazo-*m*-xylene sulphonic acid with alcohol under pressure. Minute tables, v. sol. water and alcohol.—BaA'_2 3aq. Minute plates, v. sol. water.

p-**Xylenol sulphonic acid.** Formed by dissolving *p*-xylenol in warm H_2SO_4. Hydrated leaflets.—NaA′5aq. Tables.—BaA'_2. Minute needles.

Reference.—NITRO-XYLENOL SULPHONIC ACID.

XYLENYL-AMIDOXIM *v.* DI-METHYL-BENZOIC ACID.

XYLENYL ALCOHOL *v.* DI-OXY-XYLENE.

XYLENYL CHLORIDE *v.* TETRA-ω-CHLORO-XYLENE.

XYLETIC ACID is OXY-DI-METHYL-BENZOIC ACID.

XYLIC ACID is DI-METHYL-BENZOIC ACID.

XYLIDIC ACID is TOLUENE DICARBOXYLIC ACID.

c-o-**XYLIDINE** $C_6H_3Me_2(NH_2)$ [1:2:3].—*Di-methyl-phenyl-amine. Amido-xylene.* Mol. w. 121. (223° i.V.) at 739 mm. S.G. ^{15} ·991. Obtained by reducing di-bromo-*o*-xylidine $C_6HMe_2Br_2(NH_2)$ [1:2:4:5:3] with sodium-amalgam in the cold (Töhl, *B.* 18, 2562). Got also by heating (1,2,4)-xylenol with NH_4Br and ammonio-zinc bromide at 300° (Müller, *B.* 20, 1039). Prepared from *o*-xylene by nitration and reduction (Nölting a. Forel, *B.* 18, 2671; Wroblewski, *B.* 18, 2904). Oil. When oxidised by $K_2Cr_2O_7$ and H_2SO_4 it yields a small quantity of *o*-xyloquinone [55°]. Converted by the diazo-reaction into *o*-xylenol [73°]. H_2SO_4 and HNO_3 give (4,1,2,3)-nitro-xylidine [114°] and (6,1,2,3)-nitro-xylidine [65°] (Nölting a. Stoecklin, *B.* 24, 567). —Salts: B′HClaq. Plates. Begins to sublime at 100°.—$B'HNO_3$. Needles.—$B'_2H_2SO_4$. Large plates, sl. sol. water.

Acetyl derivative $C_6H_3Me_2NHAc$. [134°] (N. a. F.); [131°] (T.; W.). Slender needles.

i-o-**Xylidine** $C_6H_3Me_2(NH_2)$ [1:2:4]. [49°]. (226°). S.G. $^{17\cdot5}$ 1·0755. Prepared from *o*-xylene by nitration and reduction (Jacobsen, *B.* 17, 159). Got also by heating *m*-toluidine hydrochloride with MeOH at 300° (Limpach, *B.* 21, 643). Monoclinic crystals, not coloured by exposure to light and air. Gives no colour with bleaching powder. Its solutions colour pine-wood yellow. On nitration it yields (6,1,2,4)-nitro-xylidine [137°] and an isomeride [80°] (N. a. S.). Yields a saffranine on oxidation together with di-amido-di-phenyl-amine (Nietzki, *B.* 19, 3163).—Salt: B′HCl aq. Prisms, v. sol. water. Yields ψ-cumidine when heated with MeOH at 310° (N. a. F.).

Acetyl derivative $C_6H_3Me_2(NHAc)$. [99°].

c-m-**Xylidine** $C_6H_3Me_2(NH_2)$ [1:3:2]. (β)-*Xylidine* (214° i.V.) at 739 mm. (N. a. F.). S.G. ^{20} ·9942 (W.). Formed by distilling *p*-amido-mesitylenic acid with lime (Schmitz, *A.* 193, 179) and by reducing *c*-nitro-*m*-xylene (Grevingk, *B.* 17, 2430). Obtained from commercial xylidine by crystallisation of the sulphate; the last mother-liquor depositing crystals which are converted into the acetyl derivative by distillation with HOAc. The acetyl derivative is saponified by treatment with dilute (25 p.c.) H_2SO_4 (Nölting a. Pick, *B.* 21, 3150; *cf.* Wróblewsky, *B.* 12, 1226). Gives *m*-xyloquinone [73°] on oxidation (Nölting a. Forel, *B.* 18, 2676). Yields (4,1,3,2)-nitro-xylidine [82°] on nitration (Nölting a. Stoecklin, *Bl.* [3] 5, 381).—Salts: B′HCl.—B′HCl ½aq. S. 9·7 at 18°. Monoclinic plates. Yields mesidine on heating with MeOH at 310°.—$B'HNO_3$. S. 8·2. Needles.—$B'_2H_2SO_4$. Very soluble needles. —$B'H_2SO_4$ 2½aq. S. 60.

Acetyl derivative [174°] (G.); [176·5°] (N. a. F.). Needles.

Benzoyl derivative [140°]. Needles. Yields benzoyl-nitro-xylidine [178°] on nitration (Hübner, *A.* 208, 318).

***s-m*-Xylidine** $C_6H_3Me_2(NH_2)$ [1:3:5]. (222° i.V.). S.G. $\frac{15}{15}$ ·972. Formed by reduction of *s*-nitro-*m*-xylene [71°] (Thöl, *B.* 18, 362; Nölting a. Forel, *B.* 18, 2678). On oxidation by $K_2Cr_2O_7$ and H_2SO_4 it gives *m*-xyloquinone [73°]. By boiling the diazo-compound with water xylenol [68°] is formed. $ClCO_2Et$ forms $C_6H_3Me_2NH.CO_2Et$ [77·5°] (Frentzel, *C. C.* 1888, 1361).—B'HCl. MeOH at 250°–300° yields isocumidine $C_6H_2Me_3(NH_2)$ [5:4:3:1] (Limpach, *B.* 21, 643).—$B'H_2SO_4$aq.—$B'HNO_3$. S. 4·66 at 13°.

Acetyl derivative [140·5°] (N. a. F.); [138°] (T.); [144·5°] (W.). Colourless plates (from alcohol or ether).

***i-m*-Xylidine** $C_6H_3Me_2(NH_2)$ [1:3:4]. (*a*)-*Xylidine.* (215°) at 745 mm. (G.). S.G. $\frac{15}{15}$ ·9184 (H.). S.V. 148·3.

Formation.—1. By reducing *i*-nitro-*m*-xylene (Deumelandt, *A.* 144, 273; Tavildaroff, *B.* 2, 553; Wroblewsky, *A.* 192, 215; 207, 91; Grevingk, *B.* 17, 2430; Wallach, *A.* 258, 331). It may be isolated from commercial xylidine by conversion into hydrochloride and several crystallisations from water; the yield being about 40 p.c. (Nölting a. Forel, *B.* 18, 2677).—2. By heating *o*- and *p*-toluidine hydrochloride with MeOH at 300° (Hofmann, *B.* 9, 1295; Limpach, *B.* 21, 640).—3. By distilling (4,3,1,5)-amido-mesitylenic acid with lime (Schmitz, *A.* 193, 177).—4. By heating *i-m*-xylenol with ammonium-zinc bromide and NH_4Br (Müller, *B.* 20, 1039).

Reactions.—1. When dissolved in H_2SO_4 (10 pts.) it yields $C_6H_2Me_2(NH_2)(NO_2)$ [1:3:4:6] [123°] on nitration (Nölting a. Collin, *B.* 17, 265).—2. The hydrochloride heated with MeOH at 310° yields mesidine.—3. $ClCO_2Et$ forms $C_6H_3Me_2.NH.CO_2Et$ [57°] (Frentzel, *C. C.* 1888, 1361).—4. When mixed with di-amido-di-phenylamine it yields a saffranine on oxidation (Nietzki, *B.* 19, 3163).—5. When *m*-xylidine (4 pts.) is heated with S (1 pt.) at 190° it gives off H_2S and forms a base $C_{16}H_{16}N_2S$ [107°] (283° at 14 mm.) which crystallises from alcohol in yellowish-white prisms and yields $C_{16}H_{15}AcN_2S$ [227°] (Anschütz a. Schultz, *B.* 22, 582). By further heating with sulphur a homologue of primuline is formed.—6. *Œnanthol* forms oily $C_{15}H_{25}NO$ (Leeds, *B.* 16, 288).—7. *Acrolein* yields $C_{11}H_{13}N$, a reddish-yellow mass which on distillation yields cryptidine $C_{11}H_{11}N$ (270°) (Leeds, *A. C. J.* 5, 1).

Salts.—B'HCl. Monoclinic prisms.—B'HCl ½aq. Plates (Staedel a. Hölz, *B.* 18, 2919).—$B'_2H_2PtCl_6$.—B'HBr.—Trimetric plates.—$B'HNO_3$.—$B'_2H_2SO_4$ 4½aq. Cubes. Loses xylidine on evaporation of its solution (Nölting a. Pick, *Bl.* [2] 50, 606).—$B'H_3PO_4$. Only phosphate formed (Lewy, *B.* 19, 2728)—$B'H_2C_2O_4$. S. 3·32 at 18°.—B'_2ZnCl_2 (Lachovitch, *M.* 9, 514).—$B'HgH_2(SO_3)_2$aq.—$B'_2Cu_2H_2(SO_3)_2$ (Denigès, *C. R.* 112, 870).

Formyl derivative $C_6H_3Me_2NH.CHO$. [111°] (G.); [114°] (G. a. M.). Got by heating the base (12 g.) with formic acid (5 g.) at 150° (Gasiorowski a. Merz, *B.* 18, 1011; Gudemann, *B.* 21, 2549). Crystals (from water). Converted by P_2S_5 at 100° into the thioformyl derivative [105°].

Mono-acetyl derivative $C_6H_3Me_2(NHAc)$. [129°]. Needles or plates (from dilute alcohol). P_2S_5 forms the compound $C_6H_3Me_2NH.CSMe$ [95°] (Jacobsen a. Ney, *B.* 22, 907).

Di-acetyl derivative $C_6H_3Me_2NAc_2$. [60°]. Formed, together with the mono-acetyl derivative, by boiling the base with Ac_2O (Wallach, *A.* 258, 301).

Benzoyl derivative $C_6H_3Me_2NHBz$. [192°]. Needles (Hübner, *A.* 208, 318). Converted by HNO_3 into the nitro-benzoyl derivative [184°] which is reduced by tin and HOAc to $C_6H_2Me_2{<}\genfrac{}{}{0pt}{}{NH}{N}{>}CPh$ [195°].

Phthalyl derivative [158°]. Prisms (from alcohol).

***p*-Xylidine** $C_6H_3Me_2(NH_2)$ [1:4:2]. [15·5°] (Michael, *B.* 26, 39). (215° i.V.) at 739 mm. (N. a. F.); (213·5° uncor.) (M.); (220°) (S.). S.G. $\frac{15}{15}$ ·980. Obtained from *m*-xylene by nitration and reduction (Schaumann, *B.* 11, 1537; Nölting a. Forel, *B.* 18, 2664; 19, 2680). Occurs to the extent of about 25 p.c. in commercial xylidine, from which it may be isolated by dissolving in warm H_2SO_4 and pouring into hot water. The sparingly soluble *m*-xylidine sulphonic acid crystallises out, and the mother-liquor, after successive treatment with $CaCO_3$ and Na_2CO_3, yields on evaporation sparingly soluble, pearly plates of sodium *p*-xylidine sulphonate, which on distillation with lime give *p*-xylidine almost without loss. May also be got from crude xylidine by means of its benzylidine derivative.

Reactions.—1. Oxidised by $K_2Cr_2O_7$ and H_2SO_4 to *p*-xyloquinone [123°], the yield being 70 p.c.—2. Converted by the diazo-reaction into *p*-xylenol [75°] (210°).—3. On heating with *sulphur* it yields $C_{16}H_{16}N_2S$ [144°], which crystallises from alcohol in yellowish needles, and yields an acetyl derivative [212°] (Anschütz a. Schultz, *B.* 22, 585).—4. The hydrochloride heated with MeOH at 290° under pressure forms ψ-cumidine (Limpach, *B.* 21, 646).—5. *Benzoic aldehyde* forms $C_6H_3Me_2.N{:}CHPh$ [102°] (Pflug, *A.* 255, 168). The same body [96°] is got by adding benzoic aldehyde to an alcoholic solution of thionyl-*p*-xylidine (Michaelis, *A.* 274, 237).

Salts.—B'HCl aq. Leaflets, subliming at 125°–130° in needles.—$B'HNO_3$. Needles.—$B'H_2SO_4$. Plates, sl. sol. water.—$B'_2H_2C_2O_4$.

Formyl derivative $C_9H_{11}NO$. [112°]. Needles (Pflug, *A.* 255, 168).

Acetyl derivative $C_6H_3Me_2NHAc$. [139°]. Prisms. Yields on nitration acetyl-nitro-*p*-xylidine [192°].

Bromo-acetyl derivative $C_6H_3Me_2.NH.CO.CH_2Br$. [145°]. Formed from bromo-acetyl bromide and *p*-xylidine in benzene (Abenius, *J. pr.* [2] 40, 435). Needles (from dilute alcohol). Boiling alcoholic potash converts it into an azine and the compound $C_6H_3Me_2NH.CO.CH_2.OEt$ [50°].

Oxalyl derivative $(C_6H_3Me_2NH)_2C_2O_2$. Formed by heating the oxalate at 130°. Needles, subliming at 125°. An oxalyl-xylidine [204°] was obtained by Genz (*B.* 3, 227) from crude, commercial xylidine.

Benzoyl derivative $C_6H_3Me_2NHBz$. [140°]. Needles.

References.—Bromo-, Chloro-, and Nitro-xylidine.

XYLIDINE SULPHONIC ACID *v.* Amido-xylene sulphonic acid and Bromo- and Nitro-xylidine sulphonic acids.

XYLIDINIC ACID *v.* Toluene dicarboxylic acid.

XYLINDEÏN. C, 65·5 p.c.; H, 4·7 p.c.; N, 1·0 p.c. A green colouring matter in green decayed wood (Rommier, *C. R.* 66, 108; Liebermann, *B.* 7, 1102). Extracted by phenol and ppd. by alcohol or ether. Four-sided blue plates, with coppery lustre. H_2SO_4 forms a green solution. Rideal (*C. N.* 53, 277) finds that the blue substance in decayed birch-wood is soluble in chloroform, while the blue resin obtained from coniferin by successive treatment with H_2SO_4 and water is insol. chloroform.

XYLITONE $C_{12}H_{18}O$. *Xylite oil.* (252°) (Pinner, *B.* 15, 580; 16, 1729); (c. 240°) (Claisen a. Ehrhardt, *B.* 22, 1013). S.G. ·935. A product of the action of HCl on acetone (P.). Formed also by the action of NaOEt on mesityl oxide in ether, and in the preparation of acetyl-acetone by the action of boiling EtOAc and NaOAc on acetone (C. a. E.). Oil, easily resinified by strong acids.

Dixylitone $C_{12}H_{20}O_2$. (310°–320°). A product of the action of HCl on acetone (Pinner).

XYLOHYDROQUINONE *v.* Hydroxyloquinone.

XYLOÏC ACID *v.* Di-methyl-benzoic acid.

XYLONIC ACID $C_5H_{10}O_6$. $[\alpha]_D = 17 \cdot 48°$. Formed by oxidising xylose with bromine (Tollens, *A.* 260, 367). Dextrorotatory. Its Ca, Zn, and Ag salts are amorphous.—SrA'_2. $[\alpha]_D = +12 \cdot 14°$.

XYLONITRILE *v.* *Nitrile* of Di-methyl-benzoic acid.

o-**XYLOQUINONE** $C_8H_8O_2$ *i.e.* $C_6H_2Me_2O_2$[1:2:3:6]. [55°]. Formed by oxidation of *c*-*o*-xylidine by $K_2Cr_2O_7$ and H_2SO_4, the yield being about 10 p.c. (Nölting a. Forel, *B.* 18, 2673). Yellow needles (by sublimation), v. sl. sol. water, m. sol. alcohol and ether.

m-**Xyloquinone** $C_6H_2Me_2O_2$ [1:3:2:5]. [73°]. Formed by oxidation either of *c*-*m*- or *s*-*m*-xylidine with $K_2Cr_2O_7$ and H_2SO_4 (Nölting a. Forel, *B.* 18, 2679). Got also by oxidation of mesidine (Nölting a. Baumann, *B.* 18, 1151). Yellow needles.

p-**Xyloquinone** $C_6H_2Me_2O_2$ [1:4:2:5]. *Phlorone. Metaphlorone.* Mol. w. 136. [124°].

Formation.—1. Occurs, together with toluquinone and other bodies, among the products of the action of MnO_2 and H_2SO_4 on coal-tar and beechwood-tar (Rommier a. Bouilhon, *C. R.* 55, 214; Gorup-Besanez a. von Rad, *Z.* [2] 4, 560; Carstanjen, *J. pr.* [2] 23, 425).—2. By oxidation of *p*-xylylene-diamine (Nietzki, *B.* 13, 472; *A.* 215, 168).—3. By oxidation of ψ-cumenol (Carstanjen, *J. pr.* [2] 23, 430).—4. By oxidation of ψ-cumidine by CrO_3 (Nölting a. Th. Baumann, *B.* 18, 1151; Sutkowski, *B.* 20, 977). 5. By distilling xylidine (213°) with H_2SO_4 and MnO_2; the yield being 5 p.c. (C.).—6. By oxidation of *p*-xylidine with $K_2Cr_2O_7$ and H_2SO_4, the yield being over 70 p.c. (Nölting, Witt, a. Forel, *B.* 18, 2667).—7. By heating diacetyl with dilute NaOHAq (Van Pechmann, *B.* 21, 1420).

Preparation.—1. Commercial xylene (130°–140°) is heated with H_2SO_4 at 100° for six days; the product poured into water; neutralised by $CaCO_3$; treated with K_2CO_3; and the K salts of the sulphonic acids fused with potash. The product is dissolved in water, acidified, and extracted with ether; and the mixture of xylenols so obtained is dissolved in warm H_2SO_4, and then diluted with water and distilled with MnO_2. Crystals of *p*-xyloquinone appear in the condenser and receiver (Carstanjen, *J. pr.* [2] 23, 427).—2. 'Yellow carbolic acid' or 'creosote,' the mother-liquor from which phenol has crystallised, is dissolved in H_2SO_4, diluted with water, and then distilled with MnO_2. The solid found in the receiver is crystallised from alcohol when the first crop of crystals is xyloquinone (E. Carstanjen, *J. pr.* [2] 23, 423).

Properties.—Long yellow needles (from benzene), sl. sol. water and cold alcohol, v. sol. ether. May be sublimed. Volatile with steam.

Reactions.—1. Distilled with *zinc-dust* gives a hydrocarbon that oxidises to terephthalic acid.—2. Reduced by aqueous SO_2 to hydroxyloquinone.—3. Conc. HCl converts it into a mixture of mono- and di-chloro-hydro-xyloquinones, $C_6HClMe_2(OH)_2$ [147°] and $C_6Cl_2Me_2(OH)_2$ [175°].

Mono-oxim $C_6H_2Me_2O(NOH)$. *Nitroso-p-xylenol.* [168°]. Formed by heating *p*-xyloquinone (2 pts.) with an alcoholic solution of hydroxylamine hydrochloride (1 pt.) (Goldschmidt a. Schmid, *B.* 18, 568; Sutkowski, *B.* 20, 978). Obtained also by adding KNO_2 and excess of HOAc to an alkaline solution of *p*-xylenol (Oliveri, *G.* 12, 162). Yellowish needles (from alcohol), v. sol. alcohol, ether, and benzene, insol. cold water. Alkalis form a deep orange-red solution. Reduced by $SnCl_2$ to amido-*p*-xylenol. Oxidised by alkaline K_3FeCy_6 to nitro-*p*-xylenol.

Di-oxim $C_6H_2Me_2(NOH)_2$. [272°]. Formed by boiling the quinone (1 mol.) with an alcoholic solution of hydroxylamine hydrochloride (2 mols.) (Sutkowski, *B.* 20, 977). V. sl. sol. alcohol, acetic acid, and benzene, insol. water. Dissolves in alkalis with a yellow colour. By tin and HCl it is reduced to xylylene-*p*-diamine. Its *di-acetyl derivative* $C_6H_2Me_2(NOAc)_2$ crystallises from acetic acid in small yellow prisms, [170°], v. sol. alcohol and benzene.

References.—Di-bromo- and Chloro-xyloquinone.

XYLORCIN *v.* Di-oxy-xylene.

XYLOSE *v.* p. 538.

XYLOSTEÏN. A glucoside in the berries of *Bonicera Xylosteum* (Hübschmann, *J.* 1856, 691; Enz, *C. C.* 1856, 393). Crystalline, insol. water, sol. alcohol and ether.

XYLOYL-BENZOIC ACID *v.* Phenyl xylyl ketone carboxylic acid.

XYLOYL-FORMIC ACID *v.* Xylyl-glyoxylic acid.

pp-**DIXYLYL** $C_{16}H_{18}$ *i.e.* [4:1:3] $C_6H_3Me_2.C_6H_3Me_2$ [3:4:1]. [125°]. Prepared by distilling mercury di-*p*-xylyl (Jacobsen, *B.* 14, 2112). Long needles (from alcohol).

Dixylyl. (290°–295°). Formed from bromo-*m* (?)-xylene and Na (Fittig, *A.* 147, 38). Liquid.

Di-xylyl (so-called). (295°) (Oliveri, *G.* 12, 158). Is got by warming *commercial* xylene with H_2SO_4, but never from xylene which has been made from xylene sulphonic acid. Hence it is probably not a benzene derivative (Armstrong, *C. J.* 45, 150). It is a colourless, fluorescent liquid, smelling like copaiba balsam.

XYLYL-ACETAMIDE *v. Acetyl derivative* of XYLIDINE and *Amide* of XYLYL-ACETIC ACID.

XYLYL-ACETIC ACID [1:3:4] $C_6H_3Me_2.CH_2.CO_2H$. [102°]. Formed from its amide, which is got by the action of yellow ammonium sulphide on xylyl methyl ketone (Willgerodt, *B.* 21, 534). Slender needles.

Amide $C_8H_9.CH_2.CO.NH_2$. [183°].

Reference.—OXY-XYLYL-ACETIC ACID.

XYLYL ALCOHOL is TOLYL-CARBINOL.

XYLYL-AMIDO-ACETIC ACID $C_{10}H_{13}NO_2$ *i.e.* [1:3:4] $C_6H_3Me_2.NH.CH_2.CO_2H$. [134°]. Formed by boiling *m*-xylidine (2 mols.) with water and chloro-acetic acid (1 mol.) (Ehrlich, *B.* 16, 205). Prisms (from dilute alcohol). Insol. water, v. sol. acids.

Xylide $C_8H_9.NH.CH_2.CO.NHC_8H_9$. [128°]. Formed by boiling xylidine (2 mols.) with chloro-acetic ether (1 mol.). Thick needles (from alcohol), insol. water and HClAq.

XYLYL-AMIDO-CROTONIC ETHER [1:3:4] $C_6H_3Me_2.NH.CMe:CH.CO_2Et$. Formed from *m*-xylidine and acetoacetic ether (Conrad a. Limpach, *B.* 21, 526). Decomposed on heating into (*Py.* 1, 3; *B.* 2, 4)-oxy-tri-methyl-quinoline, di-xylyl-urea, and alcohol.

XYLYL-AMIDO-ETHYL-PHTHALIMIDE [1:3:4] $C_6H_3Me_2.NH.C_2H_4.N:C_8H_4O_2$. [123°]. Formed by heating bromo-ethyl-phthalimide with *m*-xylidine at 140° (Newman, *B.* 21, 2197). Small needles, v. e. sol. benzene, sl. sol. cold alcohol.

DI-*m*-XYLYL-DI-AMIDO-DIAZTHIOLE $C_{18}H_{20}N_4S$ *i.e.* $S<\begin{matrix}C(NHC_8H_9):N\\C(NHC_8H_9):N\end{matrix}$. [79°]. Formed by oxidising (1,3,4)-xylyl-thio-urea with aqueous H_2O_2 (Hector, *B.* 23, 368). Insol. water. Forms a very soluble hydrochloride.—$B'_2H_2PtCl_6$. Decomposes at 214°–217°.—B'_2AgNO_3. Explodes on heating. Blackened by sunlight.—$B'C_6H_3N_3O_7$. [218°]. Yellow crystals, v. sol. alcohol. Cyanogen passed into its alcoholic solution forms $C_{18}H_{20}N_4SCy_2$ [103°].

Acetyl derivative $C_{18}H_{19}AcN_4S$. Needles.

Benzoyl derivative $C_{18}H_{19}BzN_4S$. [212°].

Nitrosamine $C_{18}H_{19}(NO)N_4S$. [146°].

XYLYLAMINE *v.* XYLIDINE and METHYL-BENZYL-AMINE.

Di-*o*-xylyl-amine $(C_8H_9)_2NH$. (330°–345°). Formed, together with xylidine, by heating (1,2,4)-xylenol with ammonio-zinc bromide and NH_4Br at 300° (Müller, *B.* 20, 1039). Liquid, solidified at a very low temperature.

Di-*m*-xylyl-amine. (305°–310°). Formed in like manner from *m*-xylidine. Oil.

Di-xylyl-amine. [162°]. Formed, together with a liquid isomeride, by heating xylidine with its hydrochloride (Girard a. Vogt).

XYLYL-BENZYL-AMINE $C_{15}H_{17}N$ *i.e.* $C_6H_3Me_2.NH.CH_2Ph$. (c. 205° at 15 mm.). Formed by heating *m*-xylidine with benzyl chloride at 160° (Joblin-Goffinet, *Bl.* [3] 6, 21). Yellowish oil, sol. alcohol and benzene.

***p*-Xylyl-benzyl-amine** [1:4:2]$C_6H_3Me_2.NH.CH_2Ph$. (322°) (Pflug, *A.* 255, 168).

***o*-XYLYL BENZYL KETONE** $C_{16}H_{16}O$ *i.e.* $C_6H_3Me_2.CO.CH_2Ph$. [95°]. (210°–220° at 25 mm.). Formed from *o*-xylene, phenyl-acetic chloride, and $AlCl_3$ (Wege, *B.* 24, 3540). Plates, sol. alcohol, v. sol. ether. Yields a crystalline oxim. NaOEt and benzyl chloride yield $C_6H_3Me_2.CO.CH(CH_2Ph)Ph$ [75°].

***m*-Xylyl benzyl ketone** [1:3:4] $C_6H_3Me_2.CO.CH_2Ph$. (350°). Formed, together with a smaller quantity of an isomeride [93°], by the action of $AlCl_3$ on a mixture of *m*-xylene and phenyl-acetic chloride (Söllscher, *B.* 15, 1681). Yields $C_6H_3Me(CO_2H)_2$ [3:4:1] on oxidation. NaOEt and benzyl chloride form oily $C_8H_9.CO.CHPh.CH_2Ph$ (365°–375°).

***p*-Xylyl benzyl ketone** $C_8H_9.CO.CH_2Ph$. (220°–230° at 26 mm.). Formed in like manner from *p*-xylene (Wege). Yields an oxim [99°] and a phenyl-hydrazide [96°]. NaOEt and benzyl chloride yield $C_8H_9.CO.CHPh.CH_2Ph$ [60·5°].

***m*-XYLYL-BENZYL-THIO-UREA** $C_8H_9NH.CS.NHCH_2Ph$. [85°]. Formed from benzyl-thiocarbimide and *m*-xylidine in alcohol (Dixon, *C. J.* 59, 558). Monoclinic prisms, v. sol. boiling alcohol and chloroform.

XYLYL BROMIDE *v.* BROMO-XYLENE.

XYLYL-*tert*-BUTANE $C_6H_3Me_2.CMe_3$. (201°). Formed from *m*-xylene, isobutyl bromide, and $AlCl_3$ (Baur, *B.* 24, 2840). Got also from isobutyl alcohol, *m*-xylene, and H_2SO_4 or $ZnCl_2$ (Nölting, *B.* 25, 791). Oil, yields mesitylenic and trimesic acids on oxidation.

XYLYL-BUTYL ALCOHOL [2:4:1] $C_6H_3Me_2.CHPr.OH$. (above 270°). Got by reducing xylyl propyl ketone with zinc-dust and KOHAq, or with sodium-amalgam (Claus, *J. pr.* [2] 46, 474). Oil, v. sol. alcohol and ether.

Tri-xylyl-butyl alcohol $(C_8H_9)_3C.CMe_2.OH$. (above 300°). Formed from -xylene, tri-chloro-*tert*-butyl alcohol, and $AlCl_3$ (Willgerodt a. Genieser, *J. pr.* [2] 37, 361). Oil, smelling like mushrooms.

***m*-XYLYL-*n*-BUTYRIC ACID** [1:3:4]$C_6H_3Me_2.CH_2.CH_2.CH_2.CO_2H$. [70°]. Formed by saponifying the amide (Claus, *J. pr.* [2] 46, 476). Needles, v. sol. hot water. May be sublimed.—BaA'_2 4aq.—CaA'_2 4aq. Prisms, v. sol. water and alcohol.

Amide $C_6H_3Me_2.C_3H_6.CO.NH_2$. [124°]. Got by heating xylyl propyl ketone with S and ammonium sulphide in sealed tubes at 250°. Flat silky needles. May be sublimed.

***p*-Xylyl-*n*-butyric acid** [1:4:2]$C_6H_3Me_2.CH_2.CH_2.CH_2.CO_2H$. [70°]. Needles, sl. sol. cold water.—BaA'_2 4aq.—CaA'_2 4aq. Needles, sol. water and alcohol.

Amide $C_8H_9.C_3H_6.CO.NH_2$. [125°]. Formed from *p*-xylyl propyl ketone (C.). Flat needles, v. sol. hot water.

***m*-Xylyl-isobutyric acid** [1:3:4] $C_6H_3Me_2.CH_2.CHMe.CO_2H$. [70°]. Flat pearly needles, sol. hot water, alcohol, and ether. May be sublimed.

Amide $C_8H_9.C_3H_6.CO.NH_2$. [120°]. Got by heating xylyl isopropyl ketone with S and ammonium sulphide at 235° (Claus, *J. pr.* [2] 46, 483). Needles, sol. hot water.

XYLYL-CARBAMIC ACID [1:3:4] $C_6H_3Me_2.NH.CO_2H$. *Ethyl ether* EtA′. [58°]. Formed from *m*-xylidine and chloroformic ether (Hofmann, *B.* 3, 657; Frentzel, *C. C.* 1888, 1361). Needles.

Xylyl-carbamic acid [1:3:5] $C_6H_3Me_2.NH.CO_2H$. *Ethyl ether* EtA′. [77·5°] (Frentzel).

DI-*p*-XYLYL-CARBINOL ([2:5:1] $C_6H_3Me_2)_2CH.OH$. [131°]. Formed by reducing di-*p*-xylyl ketone with zinc-dust and KOH (Elbs, *J. pr.* [2] 35, 484; *B.* 19, 408). White needles (from alcohol), nearly insol. Aq.

XYLYL CYANATE [1:3:4] $C_6H_3Me_2.N:CO$. (205°) (Frentzel, *C. C.* 1888, 1361).

Xylyl cyanate [1:3:5] $C_6H_3Me_2.N:CO$. (208·5°).

XYLYL CYANURATE [1:3:4] $(C_6H_3Me_2)_3N_3C_3O_3$. [162°] (Frentzel, *C. C.* 1888, 1861).

XYLYLENE ALCOHOL *v.* Di-oxy-xylene.

XYLYLENE-DI-ALLYL-DI-THIO-DI-UREA $(CH_3)_2C_6H_2(NH.CS.NH.C_3H_5)_2$ [1:4:2:6]. [112·5°]. Made from *p*-xylylene diamine and allyl thiocarbimide (Lellmann, *A.* 228, 252). Needles (from alcohol). Not decomposed on melting.

***m*-XYLYLENE-*m*-DIAMINE** $C_6H_2(CH_3)_2(NH_2)_2$ [1:3:4:6]. *m-Di-amido-m-xylene* [105°]. Formed by reduction of nitro-xylidine [123°] or of di-nitro-xylene [93°] (Fittig, *A.* 147, 18; Grevingk, *B.* 17, 2426; Witt, *B.* 21, 2419). White crystals. Sublimable. Does not yield a eurhodine on boiling with nitroso-dimethyl-aniline, NaOAc, and HOAc. — B″2HCl. — $B''H_2SnCl_4$.—$B''H_2SO_4$. Crystalline, v. sol. Aq.

***m*-Xylylene-*o*-diamine** $C_6H_2Me_2(NH_2)_2$ [1:3:5:6] [78·5°]. Formed by reduction of [2:4:1] $C_6H_3Me_2.N_2.C_6H_2Me_2.NH_2$ [1:3:5:6] (Nölting a. Forel, *B.* 18, 2683) and also by the action of tin and HClAq on di-bromo-di-nitro-*m*-xylene [191°] (Jacobsen, *B.* 21, 2821), and on (5,1,3,6)-nitro-xylidine (Hofmann, *B.* 9, 1298). Plates (from water), sl. sol. cold benzene, sol. ether.

***m*-Xylylene-*m*-diamine** $C_6H_2Me_2(NH_2)_2$ [1:3:4:2]. [64°]. Formed by reduction of nitro-xylidine [78°] or of di-nitro-*m*-xylene [82°] (Grevingk, *B.* 17, 2426). White needles. Gives a Bismarck brown with nitrous acid and a chrysoïdine with diazobenzene.

***p*-Xylylene-*o*-diamine** $C_6H_2Me_2(NH_2)_2$ [1:4:2:3]. [75°]. Formed by reduction of *c*-di-nitro-*p*-xylene (Lellmann, *A.* 228, 251; Nölting, *B.* 19, 145). White needles (by sublimation). Gives a deep-red colour with $FeCl_3$.

***p*-Xylylene-*m*-diamine** $C_6H_2Me_2(NH_2)_2$ [1:4:2:6]. [102°]. Formed by reducing (2,6,1,4)-di-nitro-xylene (L.; N.). Needles (by sublimation). Behaves like a *m*-diamine.

***p*-Xylylene-*p*-diamine** $C_6H_2Me_2(NH_2)_2$ [1:4:2:5]. [142°] (S.); [147°] (N. a. F.); [150°] (N.). *Formation.*—1. By reduction of xylene-azoxylidine (amido-azo-xylene) [2:5:1] $C_6H_3Me_2.N_2.C_6H_2Me_2.NH_2$ [1:2:5:4] by zinc and HClAq (Nietzki, *B.* 13, 471; Nölting a. Forel, *B.* 18, 2685).—2. By reduction of nitro-*p*-xylidine [142°] (Nölting, Witt, a. Forel, *B.* 18, 2666; von Kostanecki, *B.* 19, 2318; Marckwald, *B.* 23, 1021).—3. By reduction of the di-oxim of *p*-xyloquinone $C_6H_2Me_2(NOH)_2$ with tin and HCl (Sutkowski, *B.* 20, 979).

Properties.— Colourless needles, sol. hot water and alcohol, m. sol. benzene and ether. Yields xyloquinone [123°] on oxidation. Not oxidised by exposure to air. May be sublimed.

Salts.—B″2HCl. Colourless leaflets. — $B''H_2SO_4$. Crystalline meal.

***o*-Xylylene *exo*-diamine** [1:2] $C_6H_4(CH_2.NH_2)_2$. Formed by heating the phthalimide $C_6H_4(CH_2.N:C_2O_2:C_6H_4)_2$ with conc. HClAq at 200° (Strassmann, *B.* 21, 579). Alkaline liquid, smelling strongly like ammonia. Absorbs CO_2. Gives with $FeCl_3$ a pp. of yellowish-red needles.—B″2HCl.—$B''2HAuCl_4$. Yellow plates.—$B''2C_6H_3N_3O_7$. Yellow needles, decomposing above 170° without melting.

Acetyl derivative $C_8H_{10}Ac_2N_2$. [146°].

Benzoyl derivative $C_8H_{10}Bz_2N_2$. [168°].

***m*-Xylylene-*exo*-diamine** [1:3] $C_6H_4(CH_2.NH_2)_2$. (247°). Formed by the action of conc. hydrochloric acid at 220° on the $C_6H_4(CH_2.N:C_8H_4O_2)_2$ [237°], which is got by heating potassium phthalimide with di-ω-bromo-*m*-xylene (Brömme, *B.* 21, 2705). Liquid, sol. water, miscible with alcohol and ether. Absorbs CO_2. — B″2HCl. Needles (from water). — $B''2H_2PtCl_6$.—$B''C_6H_3N_3O_7$. Yellow spangles, decomposing at 187°.

Acetyl derivative $C_6H_4(CH_2.NHAc)_2$. [119°]. Crystalline mass, v. sol. hot water.

Reference.—Nitro-xylylene-diamine.

XYLYLENE-BENZENYL-AMIDINE *v.* Benzenyl-xylylene-diamine.

XYLYLENE BROMIDE *v.* Di-bromo-xylene.

XYLYLENE-CHLORO-MALONIC ETHER *v.* Chloro-xylylene-malonic ether.

Xylylene-*exo*-di-chloro-malonic ether *v.* Di-chloro-phenylene-di-methyl-di-malonic ether.

XYLYLENE-ETHENYL-AMIDINE $C_{10}H_{12}N_2$ *i.e.* $CMe\left<{NH \atop N}\right>C_6H_2Me_2$. Formed by reducing $C_6H_2Me_2(NO_2)(NHAc)$ [1:3:5:4] with tin and HCl (Hobrecker, *B.* 5, 922). Resinous mass.—B′HCl. Large needles.—$B'_2H_2PtCl_6$.—$B'HNO_3$ Long needles.

XYLYLENE IODIDE *v.* Di-iodo-xylene.

XYLYLENE-DI-MALONIC ACID *v.* Phenylene-di-methyl-di-malonic acid.

***o*-XYLYLENE SULPHIDE** C_8H_8S *i.e.*  $C_6H_4\left<{CH_2 \atop CH_2}\right>S$. [c. 0°]. Formed by heating di-ω-bromo-*o*-xylene with K_2S (Leser, *B.* 17, 1824; Hjelt, *B.* 22, 2904). Oil, smelling like mercaptan. Very unstable, quickly turning into a black resin.—B'_2HgCl_2. Long needles.

Methylo-iodide B′MeI. [155°].

Di-xylylene disulphide [1:3:4:5] $C_6H_2Me_2:S_2:C_6H_2Me_2$ [5:4:3:1]. [118°]. Formed by heating xylylene-diazosulphide at 200°–250° (Jacobsen a. Ney, *B.* 22, 911). Conc. H_2SO_4 forms a blue liquid, remaining blue on dilution.

***u*-DI-XYLYL-ETHANE** $C_{18}H_{22}$ *i.e.* $CH_3.CH(C_8H_9)_2$. (314°). S.G. $\frac{20}{4}$ ·966. Formed from ethylidene chloride, *m*-xylene, and $AlCl_3$ (Anschütz, *B.* 18, 665; *A.* 235, 326). Oil.

Reference.—Chloro-di-xylyl-ethane.

DI-XYLYL-ETHYLENE $C_{18}H_{20}$ *i.e.* $C_6H_3Me_2.CH:CH.C_6H_3Me_2$. *Tetra-methyl-stilbene.* [106°]. (325°–340°). Formed by distilling

$C_6H_3Me_2.CH_2.CH_2Cl$, which is got from di-chloro-di-ethyl oxide, *m*-xylene, and H_2SO_4 (Hepp, *B.* 7, 1416). Spangles (from alcohol), sol. ether and CS_2. Unites with bromine. Oxidised by dilute HNO_3 to (1,3,4)-di-methyl-benzoic acid [122°].

Di-xylyl-ethylene $C_6H_3Me_2.CH{:}CH.C_6H_3Me_2$. [157°]. Formed in like manner from *p*-xylene. Plates (from alcohol). Less soluble than the preceding isomeride.

Tetra-xylyl-ethylene $(C_6H_3Me_2)_2C{:}C(C_6H_3Me_2)_2$. [245°]. Formed from xylene, $CHCl_3$, and $AlCl_3$ (Schwarz, *B.* 14, 1528). Yellow plates.

***m*-XYLYL-ETHYLENE-DIAMINE** $C_6H_3Me_2NH.C_2H_4.NH_2$. (274°). Formed from *m*-xylyl-amido-ethyl-phthalimide and HCl (Newman, *B.* 24, 2197).—B'HCl. [173°].—$B'_2H_2PtCl_6$.—$B'C_6H_3N_3O_7$. [141°]. Reddish-yellow needles, v. e. sol. alcohol.

DI-*m*-XYLYL-ETHYLENE DIKETONE $C_2H_4(CO.C_6H_3Me_2\,[4{:}3{:}1])_2$. [129°]. Formed from *m*-xylene, succinyl chloride, $AlCl_3$ and CS_2 (Claus, *B.* 20, 1375). Needles, insol. water, v. sol. alcohol and ether. Dilute HNO_3 oxidises it to (1,3,4)-di-methyl-benzoic acid.

Oxim $C_2H_4(C(NOH).C_8H_9)_2$. [140°].

Phenyl-hydrazide $C_2H_4(C(N_2HPh).C_8H_9)_2$. [189°]. Crystals.

Di-*p*-xylyl ethylene diketone $C_2H_4(CO.C_6H_3Me_2\,[2{:}4{:}1])_2$. [123°]. Formed from *p*-xylene, succinyl chloride, $AlCl_3$, and CS_2 (Claus). Needles.

***m*-XYLYL ETHYL KETONE** [1:3:4] $C_6H_3Me_2.CO.C_2H_5$. (239°). Light oil, with aromatic odour, not solid at −10° (Claus, *J. pr.* [2] 43, 140). Yields (1,3,4)-di-methyl-benzoic acid on oxidation.

Phenyl-hydrazide [126°]. Plates, v. sol. hot water, alcohol, and ether.

***p*-Xylyl ethyl ketone** [4:1:2] $C_6H_3Me_2.CO.C_2H_5$. (238° uncor.). Formed from *p*-xylene, $AlCl_3$, and propionyl chloride (Claus a. Fickert, *B.* 19, 3182). Oil. Oxidised by $KMnO_4$ to $C_6H_3Me_2.CO.CH_2.CO_2H$ [132°] and some (4,1,2)-di-methyl-benzoic acid.

***m*-XYLYL ETHYL KETONE CARBOXYLIC ACID** [4:2:1] $C_6H_3Me_2.CO.CH_2.CH_2.CO_2H$.

Di-methyl-benzoyl-propionic acid. [108°]. Formed from *m*-xylene, succinyl chloride, $AlCl_3$, and CS_2 (Claus, *B.* 20, 1376). Needles, v. sol. hot water, insol. cold.—NH_4A'.—KA' 4aq. V. sol. water.—NaA' 4aq. Needles.—BaA'_2 3aq. Needles.—PbA'_2: white pp.—AgA': white crystalline pp.

***p*-Xylyl ethyl ketone carboxylic acid** [4:1:2] $C_6H_3Me_2.CO.CH_2.CH_2.CO_2H$. [84°]. Formed from *p*-xylene in like manner (C.). Colourless needles.

XYLYL-DI-ETHYL-PHOSPHINE $C_6H_3Me_2.PEt_2$. (260°). Formed by the action of $ZnEt_2$ on $C_6H_3Me_2.PCl_2$ (Czimatis, *B.* 15, 2016). Thick, colourless oil. Yields B'MeI [90°], $B'_2Me_2PtCl_6$ [202°], and B'EtI [136°].

$C_8H_9N\left<\begin{array}{l}CH{:}CH\\CH{:}N\end{array}\right.$

$C_8H_9N\left<\begin{array}{l}CH=CH\\C(SH){:}N\end{array}\right.$

***m*-XYLYL-GLYOXALINE** $C_8H_9N\left<\begin{array}{l}CH{:}CH\\CH{:}N\end{array}\right.$ [82°]. (279°). Formed by the action of HNO_3 on $C_8H_9N\left<\begin{array}{l}CH=CH\\C(SH){:}N\end{array}\right.$ [192°], which is got by the action of HCl on the product of the action of amido-acetal on *m*-xylyl-thio-urea (Marckwald, *B.* 25, 2368). Sl. sol. water.—*Aurochloride* [165°].—*Picrate.* [159°]. Yellow needles, m. sol. chloroform.

***o*-XYLYL-GLYOXYLIC ACID** [4:3:1] $C_6H_3Me_2.CO.CO_2H$. [92°]. Formed by oxidising *o*-xylyl methyl ketone with alkaline K_3FeCy_6 (Buchka a. Irish, *B.* 20, 1766).—BaA'_2.

***m*-Xylyl-glyoxylic acid** [4:2:1] $C_6H_3Me_2.CO.CO_2H$. [54°]. Formed by oxidising *m*-xylyl methyl ketone with $KMnO_4$ (Claus, *B.* 19, 231; *J. pr.* [2] 43, 142). Flat prisms. Yields (4,2,1) di-methyl-benzoic acid on boiling with dilute HNO_3. Gives rise to $C_8H_9.CH(OH).CO_2H$ [119°] on reduction.—CaA'_2 2aq. Needles.—BaA'_2 2aq.—AgA'. Needles, sol. hot water.

***p*-Xylyl-glyoxylic acid** [5:2:1] $C_6H_3Me_2.CO.CO_2H$. [70°–80°]. Formed by oxidation of *p*-xylyl methyl ketone by aqueous $KMnO_4$ (Claus a. Wollner, *B.* 18, 1859). Crystalline, v. sol. alcohol, ether, and HOAc, v. sl. sol. water. Splits up above 200° into CO_2 and di-methyl-benzoic aldehyde. Oxidised by HNO_3 to $C_6H_3Me_2.CO_2H$. Ac_2O and NaOAc yield di-methyl-cinnamic acid.—BaA'_2 6aq: small felted needles.—CaA'_2 3aq.—AgA': crystalline pp.

Ethyl ether EtA'. Oil.

XYLYL GLYOXYLIC ALDEHYDE [1:3:4] $C_6H_3Me_2.CO.CHO$. *Oxim* [95°]. Formed from xylyl methyl ketone, NaOEt, and $C_5H_{11}NO_2$ (Söderbaum, *B.* 25, 3463). Needles (from benzene-ligroïn). Acetic anhydride gives the acetyl derivatives of the *syn*-oxim $C_8H_9.CO.CH{:}NOAc$ [54°] decomposed by alkalis with formation of $C_6H_3Me_2.CO_2H$ [126°] and by hot Ac_2O yielding $C_6H_3Me_2.CO.CN$ [47°]. AcCl converts the oxim into $C_6H_3Me_2.C(OH)_2.CH{:}NOAc$ [142°], whence cold NaOH forms $C_6H_3Me_2.CH(OH).CO_2H$ [103°], while NaOHAq at 50° forms 'xylyl formoin' $C_8H_9.CO.CH(OH).CO.CO.C_8H_9$ [155°].

DI-XYLYL-GUANIDINE $HN{:}C(NH.C_8H_9\,[1{:}2{:}4])_2$. [158°]. Formed by the action of PbO and alcoholic ammonia on di-xylyl-thio-urea (Hofmann, *B.* 9, 1295). Needles, (from alcohol).

XYLYL-HYDRAZINE [4:2:1] $C_6H_3Me_2NH.NH_2$. [85°]. Formed from xylidine by diazotisation followed by reduction with Na_2SO_3, the resulting $C_8H_9.N_2H_2.SO_3Na$ ½aq being then treated with zinc-dust and HOAc (Klauber, *M.* 11, 282). Pale-yellow needles, v. sl. sol. water, v. sol. alcohol. Reduces Fehling's solution on warming. On heating with aceto-acetic ether it yields a crystalline body [203°] reduced in alcoholic solution by Na to oxy-xylyl-methyl-pyrazole.

Salt.—C'HCl 2aq. [183°]. Small needles.

Di-*o*-xylyl-hydrazine [3:2:1] $C_6H_3Me_2NH.NHC_6H_3Me_2$ [1:2:3]. [141°]. *c-Hydrazo-o-xylene.* Got by heating nitro-*o*-xylene (20 g.) with NaOH (20 g.), alcohol (100 c.c.) and zinc-dust (25 g.), and reducing the product with alcoholic ammonium sulphide (Nölting a. Stricker, *Bl.* [2] 50, 613). White needles, sol. alcohol and ether. Easily oxidised by air.

***u*-Di-*o*-xylyl-hydrazine** $N_2H_2(C_6H_3Me_2[1{:}3{:}4])_2$. [107°]. Formed by reducing nitro-*o*-xylene with sodium-amalgam (N. a. S.). Yellowish white needles, sol. alcohol.

Di-*m*-xylyl-hydrazine $N_2H_2(C_6H_3Me_2[1:3:5])_2$. [125°]. Obtained from *s*-nitro-*m*-xylene (N. a. S.). Needles, easily oxidised by air.

***u*-Di-*m*-xylyl-hydrazine** $N_2H_2(C_6H_3Me_2[1:2:4])_2$. [122°]. Got by warming nitro-*m*-xylene (30 g.) with NaOH (30 g.), zinc-dust (40 g.), and alcohol (250 c.c.) and treating the xylene-azo-xylene so obtained with alcoholic ammonia and H_2S (N. a. S.). White needles, sol. alcohol and ether.

Di-*p*-xylyl-hydrazine $N_2H_2(C_6N_3Me_2[1:2:5])_2$. [145°]. Formed from nitro-*p*-xylene (N. a. S.). Needles, not affected by air.

XYLYLIC ACID *v.* Di-methyl-benzoic acid.

α-Xylylic acid *v.* Tolyl-acetic acid.

***p*-XYLYLIDENE-DI-IMINE** $C_6H_4(CH:NH)_2$ [1:4]. Formed by the action of alcoholic NH_3 or dry NH_3 gas upon terephthalic aldehyde (Oppenheimer, *B.* 19, 576). Glassy brittle crystals. V. sl. sol. alcohol and ether.

DI-XYLYL-KETONE $CO(C_6H_3Me_2)_2$. (c. 340°). Obtained from (*m*?)-xylene, $COCl_2$, and $AlCl_3$ (Ador a. Rilliet, *B.* 11, 399). Liquid, not solid at −60°. Split up by long boiling into H_2O and $C_{17}H_{16}$.

Di-*p*-xylyl ketone [2:5:1] $C_6H_3Me_2.CO.C_6H_3Me_2$ [1:2:5]. (327° uncor.). Formed from *p*-xylene, CS_2, and $COCl_2$ in closed vessels; the yield being 55 p.c. (Elbs, *J. pr.* [2] 35, 481). Oil. Quickly decomposed by distillation into H_2O and (*B.* 2, 1′,4′)-tri-methyl-anthracene [227°]. Reduced by zinc-dust and alcoholic KOH to di-*p*-xylyl-carbinol [131°].

Di-xylyl-tetraketone $C_8H_9.CO.CO.CO.CO.C_6H_3Me_2$ [4:3:1]. [180°]. Formed by the action of cold HNO_3 (S.G. 1·4) on $C_8H_9.CO.CH(OH).CO.CO.C_8H_9$ (Söderbaum, *B.* 25, 3475). Scarlet needles (from CS_2). On dissolving in HOAc and ppg. by water it yields a dihydrate [100°] $C_{20}H_{22}O_6$.

XYLYL MERCAPTAN $C_6H_3Me_2.SH$. (214°). S.G. ^{15} 1·036. Got by treating xylene sulphonic chloride with Zn and dilute H_2SO_4 (Yssell, *Z.* 1865, 360), and also by heating xylyl ethyl xanthate with alcoholic potash (Leuckart, *J. pr.* [2] 41, 192). Liquid. — $Hg(S.C_8H_9)_2$. — $Pb(S.C_8H_9)_2$. Yellow powder.

TRI-*p*-XYLYL-METHANE $CH\{C_6H_3Me_2\}_3$. [188°]. (above 360°). From di-*p*-xylyl-carbinol, *p*-xylene, and P_2O_5 by boiling for four hours (Elbs, *J. pr.* [2] 35, 484). Crystalline grains (from alcohol), v. sol. ether and benzene.

***o*-XYLYL METHYL KETONE** [4:3:1] $C_6H_3Me_2.CO.CH_3$. (246°). Formed from *o*-xylene, AcCl, and $AlCl_3$ (Claus, *B.* 18, 1856; 19, 232; *J. pr.* 1890, 410). Oil, smelling like coumarin (Armstrong a. Kipping, *C. J.* 63, 81). Yields (4,3,1)-di-methyl-benzoic acid on oxidation. Conc. HClAq forms $C_{20}H_{22}O$ [114°]. P_2O_5 gives a body melting at 165°. Zinc-dust reduces the ketone to $C_8H_9.CH(OH).CH_3$ (257°).

Oxim $C_8H_9.C(NOH).CH_3$. [85°]. Prisms (from dilute alcohol), converted by AcCl into $C_8H_9.C(NOAc).CH_3$ [72°].

Phenyl-hydrazide. Colourless prisms.

***m*-Xylyl methyl ketone** [4:2:1] $C_6H_3Me_2.CO.CH_3$. (228°). Formed from *m*-xylene, AcCl, and $AlCl_3$ (Claus, *B.* 19, 230). Obtained also by boiling *m*-xylene with HOA $ZnCl_2$, and $POCl_3$ (Frey, *J. pr.* [2] 43, 120). Oi smelling like peppermint. Not condensed b HClAq. Yields $C_{10}H_9Br_3O$ [69°]. Reduction b HI yields $C_6H_3Me_2.CH_2.CH_3$ (184°) (Claus, *J. p* [2] 45, 830). HNO_3 gives $C_{20}H_{18}N_2O_4$ [108 (Claus, *J. pr.* [2] 41, 492).

***p*-Xylyl methyl ketone** [5:2:1] $C_6H_3Me_2.CO.CH_3$. (225° uncor.). S.G ^{15} ·9962. V.D. 4·93. Formed from *p*-xylen AcCl, and $AlCl_3$ (Claus a. Wollner, *B.* 18, 1856 Oil, v. sol. alcohol and ether. Oxidised by sol aqueous $KMnO_4$ to *p*-xylyl-glyoxylic acid. Dilut HNO_3 forms di-methyl-benzoic and methyl phthalic acids.

Oxim $C_8H_9.C(NOH).CH_3$. [58°].

XYLYL METHYL KETONE CARBOXYLI ACID *v.* Methyl-benzoyl-acetic acid.

XYLYL-DI-METHYL-PHOSPHINE $C_6H_3Me_2.PMe_2$. (230°). Formed from ZnMe and $C_6H_3Me_2.PCl_2$ (Czimatis, *B.* 15, 2016). Oil. Unites with CS_2, forming a compound [115°].

XYLYL-METHYL-THIOHYDANTOÏN

[1:3:4] $C_6H_3Me_2.N\left<\begin{matrix}CO.CH_2\\CS.NH\end{matrix}\right.$. [165°]. Formed from xylyl-thiocarbimide and alanine (Marckwald, *B.* 24, 3282). Needles, v. sol. alcohol.

XYLYL PENTADECYL KETONE $C_6H_3Me_2.CO.C_{15}H_{31}$. [37°]. (269° at 15 mm.). Formed from *m*-xylene, palmityl chloride, and $AlCl_3$ (Krafft, *B.* 21, 2269). Small plates, yielding di-methyl-benzoic acid [126°] on oxidation.

XYLYL PHENYLAMYL KETONE $C_6H_3Me_2.CO.CHPh.C_4H_9$. [91·5°]. Formed by Friedel and Craft's method (Wege, *B.* 24, 3541).

XYLYL-PHENYL- *v.* Phenyl-xylyl-.

TRI-XYLYL PHOSPHATE $PO(OC_6H_3Me_2)_3$. The *o*- and *p*- compounds are formed by heating *o*- and *p*-xylenol with $POCl_3$ (Kreysler, *B.* 18, 1702). They are oils, v. sol. ether, alcohol, and benzene.

***m*-XYLYL-PHTHALIDE**

$C_6H_4\left<\begin{matrix}CH(C_6H_3Me_2)\\CO\end{matrix}\right>O$. [84°]. Got by heating $C_6H_3Me_2.CO.C_6H_4.CO_2H$ with zinc and HCl (Gresly, *A.* 234, 237). Needles (from alcohol), sl. sol. benzene.

XYLYL-PROPIONIC ACID [1:3:4] $C_6H_3Me_2.CH_2.CH_2.CO_2H$. [105°]. Formed by saponifying the amide. Silky needles, v. sol. hot water.—BaA'_2 6aq. Plates, m. sol. water.—CaA'_2 4aq.—AgA'. White powder.

Amide $C_6H_3Me_2.C_2H_4.CO.NH_2$. [107°]. Got by heating the oxim of *m*-xylyl ethyl ketone with yellow ammonium sulphide under pressure (Claus, *J. pr.* [2] 46, 477). Needles, sol. hot water.

***m*-XYLYL PROPYL KETONE** $C_{12}H_{16}O$ i.e. [4:2:1] $C_6H_3Me_2.CO.Pr$. (251°). Formed from *m*-xylene, butyryl chloride and $AlCl_3$ (Claus, (*J. pr.* [2] 46, 474). Oil, v. sol. alcohol and ether. Yields *m*-xylyl-glyoxylic acid [54°] on oxidation with $KMnO_4$.

Oxim. Crystals, v. e. sol. alcohol.

***p*-Xylyl propyl ketone** [5:2:1] $C_6H_3Me_2.CO.Pr$. (249°). Formed in like manner from *p*-xylene. Light oil.

Oxim [47°]. Colourless needles.

***o*-Xylyl isopropyl ketone** [4:3:1] $C_6H_3Me_2.CO.Pr$. (258°). Oil, smelling like turpentine (Claus, *J. pr.* [2] 46, 484). Yields di-methyl-benzoic acid [163°] on oxidation.

Oxim [68°]. Large prisms.

***m*-Xylyl isopropyl ketone** [4:2:1] $C_6H_3Me_2.CO.Pr$. (245°). Oil, yielding *m*-xylyl-glyoxylic acid on oxidation by $KMnO_4$.

Oxim [97°]. Prisms (from alcohol).

Phenyl-hydrazide [129°]. Crystals.

***p*-Xylyl isopropyl ketone** [5:2:1] $C_6H_3Me_2.CO.Pr$. (240°). Formed from *p*-xylene, isobutyryl chloride, and $AlCl_3$ (Claus, *J. pr.* [2] 46, 484). Oil, smelling like mushrooms.

Oxim [76°]. Plates and prisms.

TETRA-*o*-XYLYL SILICATE $Si(OC_6H_3Me_2)_4$. (c. 460°). Formed by heating *o*-xylenol with $SiCl_4$, the yield being 85 p.c. of the theoretical amount (Hertkorn, *B.* 18, 1691). Large prisms.

Tetra-*m*-xylyl silicate $Si(OC_6H_3Me_2)_4$. (453°–457°). Formed, in like manner, from *m*-xylenol. Oil.

***m*-XYLYL THIOCARBIMIDE** C_9H_9NS *i.e.* [4:2:1] $C_6H_3Me_2.N:CS$. Formed from di-xylyl-thio-urea and P_2O_5 (Hofmann, *B.* 9, 1295). Crystals. Converted by PhOEt and $AlCl_3$ into $C_8H_9NH.CS.C_6H_4.OEt$ [140°] (Gattermann, *B.* 25, 3530).

XYLYL ETHYL DITHIOCARBONATE $CS(OEt).SC_6H_3Me_2$. Formed from potassium xanthate and *m*-diazo-xylene chloride (Leuckart, *J. pr.* [2] 41, 192). Oil, converted by heating with alcoholic potash into xylyl mercaptan (214°).

DI-XYLYL-THIO-UREA $CS(NH.C_6H_3Me_2[1:2:4])_2$. [153°]. Formed by digesting xylidine with CS_2 as long as H_2S escapes (Hofmann, *B.* 9, 1295). Crystals (from alcohol).

XYLYL-UREA $NH_2.CO.NHC_6H_3Me_2[1:2:4]$. [186°]. Formed from crude xylidine sulphate and potassium cyanate (Genz, *B.* 8, 226). Needles (from alcohol).

***s*-Xylyl urea** $NH_2.CO.NH.C_6H_3Me_2[1:3:5]$. [162°] (Frentzel, *C. C.* 1888, 1361).

Di-*s*-xylyl-urea $CO(NHC_6H_3Me_2[1:3:5])_2$. [275°] (F.); [251°] (G. a. C.). Formed from *s*-xylidine and $COCl_2$ (F.). Formed also from *m*-xylyl cyanate and xylidine (Gattermann a. Cantzler, *B.* 25, 1089). Needles.

Di-*m*-xylyl-urea $CO(NH.C_6H_3Me_2[1:2:4])_2$. [263°]. A product of the distillation of *m*-xylyl-amido-crotonic acid (Conrad a. Limpach, *B.* 21, 527). Sublimes when melting.

Di-xylyl-urea $CO(NHC_6H_3Me_2)_2$. Formed by heating urea (1 pt.) with crude xylidine (8 pts.). Felted needles (from hot alcohol), not melted at 250° (Genz, *B.* 3, 226).

Reference.—METHYL-BENZYL-UREA.

Y

YTTERBIUM. Yb. At. w. c. 173. This name is given to the metal, not yet isolated, of an earth separated by Marignac, in 1878, from crude erbia obtained from *gadolinite* or *euxenite*. The claim of ytterbia to rank as a definite homogeneous compound is not yet satisfactorily established.

The discovery of a new earth in a mineral from Ytterby in Sweden was announced in 1788 by Gadolin; in 1797 Eckeberg confirmed the discovery. The new earth was named *yttria*, and the mineral from which it was obtained was called *gadolinite*. Researches into the nature of yttria were conducted by Berzelius in 1819 (*v. Lehrbuch* [5th ed.] 2), Mosander in 1839 and 1843 (*J. pr.* 30, 27), Scheerer in 1842, Clève and others. In 1878 Marignac made a careful examination of erbia (*A. Ch.* [5] 14, 247); he fractionally decomposed erbium nitrate by heat, and obtained an earth which he called *ytterbia*. The erbia used by Marignac was pink, and gave, in solution, an absorption spectrum; the new earth was white and showed no absorption spectrum. Nilson (*B.* 12, 554; 13, 1439 [1879–80]) prepared ytterbia, but found a reacting weight for the earth different from that assigned to it by Marignac. By repeated fractional decomposition by heat of the nitrate of ytterbium, Nilson separated another earth which he called scandia (*cf.* SCANDIUM, this vol., p. 431). Nilson (*B.* 13, 1430) in 1879 made a fuller examination of ytterbia, and determined the at. w. of the metal of this earth, and the properties of several salts of the metal. In this memoir Nilson asserted that *erbia* was separable into seven distinct earths: erbia proper, scandia, terbia, thulia, ytterbia, yttria, and Soret's X (afterwards called holmia). (*cf.* ERBIUM, vol. ii. p. 456; and METALS, RARE, vol. iii. p. 245).

Occurrence.—Along with erbia, scandia, yttria, &c., in very small quantities in a few rare Scandinavian minerals, chiefly in *gadolinite* and *euxenite*. Nilson (*l.c.*) obtained c. 20 g. ytterbia from 6–7 kilos. of the crude earths prepared from c. 15 kilos. gadolinite.

Preparation of ytterbia.—Nilson (*B.* 13, 1430) mixed finely powdered *euxenite* or *gadolinite*, c. 400 g. at a time, with four times its weight of $KHSO_4$, fused over a powerful burner, pulverised the fused mass, and thoroughly exhausted with cold water; he ppd. the aqueous solution by ammonia, washed the ppd. hydrated oxides, and dissolved in HNO_3Aq; after boiling the solution for some time, and filtering, he ppd. by oxalic acid, washed the pp., dried it, and heated strongly until it was decomposed. The crude earths thus obtained were freed from K_2CO_3 by boiling with water, and were then dissolved in HNO_3Aq; the solution was evaporated to dryness, and the residue was fused until red vapours began to come off. The reddish-yellow, opaque solid was then treated with boiling water, whereby a reddish-yellow pp. was formed, which was filtered off by means of a suction-pump. (This pp. contained oxide of Th, along with oxides of Ce, Fe, and U.) The reddish filtrate was evaporated to dryness, and the solid nitrates thus obtained were partly decomposed by heating, the soluble (undecomposed) portion removed by solution in water, the residue dissolved in HNO_3Aq, the solution evaporated to dryness, the residue partly decomposed by heating, the undecomposed nitrates were removed by washing with water, the residue was dissolved in HNO_3Aq, and so on. After thirty repetitions of this process a solution was obtained that showed merely a trace of red colour after thirty-five repetitions the solution was quite colourless, and showed only two faint absorption bands, one in the green and the other in the red; after forty repetitions a solution was obtained which gave only the red band; and when the process of partial decomposition by heat had been repeated sixty-eight times a solution in HNO_3Aq was obtained which showed no trace of an absorption spectrum. This solution was saturated with H_2S, the small yellowish-brown pp. of PtS_2 was filtered off, the filtrate was ppd. by pure oxalic acid, the pp. was washed, dried, and decomposed by heating strongly, and pure ytterbia was thus obtained. For a modification of this method of separating ytterbia from accompanying earths *v.* Auer von Welsbach (*M.* 4, 630).

Atomic weight of ytterbium.—The metal has not been isolated; the at. w. was determined by Nilson (*B.* 13, 1433) by dissolving pure Yb_2O_3 (*v. supra*) in HNO_3Aq, adding a suitable quantity of H_2SO_4Aq, evaporating on a water-bath to drive off HNO_3, then on a sand-bath, and finally over a flame until all free H_2SO_4 was removed, weighing the $Yb_2(SO_4)_3$ thus obtained, and analysing it. Nilson dissolved pure Yb_2O_3 in HNO_3Aq, evaporated to dryness, partially decomposed the nitrate by heat, treated with water, &c., as described *supra*, and in this way obtained seven fractions, each of which was converted into sulphate. The results are presented in the following table:—

Weight of Yb_2O_3 taken	Weight of sulphate formed	Pctge. composition of sulphate		Atomic w. of Yb.
		Yb_2O_3	SO_3	
1·0063	1·6186	62·171	37·829	173·21
1·0139	1·6314	62·149	37·851	173·03
·8509	1·3690	62·155	37·845	173·08
·7371	1·1861	62·145	37·855	173·00
1·0005	1·6099	62·147	37·853	173·01
·8090	1·3022	62·126	37·874	172·84
1·0059	1·6189	62·134	37·866	172·91
Mean		62·147	37·853	173·01

Chemical relations of ytterbium.—If Yb is really a homogeneous substance, it must be placed in Series 10 of Group III. in the periodic classification of the elements. This group contains the following elements:—

Even series—

2	4	6	8	10	12
B (11)	Sc (44)	Y (89)	La (139)	Yb (173)	—

Odd series—

3	5	7	9	11
Al (27)	Ga (70)	In (114)	—	Tl (204)

A comparison of the position of Yb with the positions of elements placed in Series 10 (*v.* table on p. 811 of vol. iii.) shows that Yb ought to be decidedly more metallic than B, and somewhat more metallic than Al, Ga, or In; the data, however, are too meagre to allow a detailed comparison to be made. Little is known of the properties of compounds of Yb; but what is known broadly confirms the conclusions drawn from the position of the element in the periodic scheme of classification (*cf.* EARTHS, METALS OF THE, vol. ii. p. 424).

Ytterbium oxide Yb_2O_3. (*Ytterbia.*) A very heavy, white, infusible powder; slowly acted on by acids when cold or gently warmed, but readily dissolved by dilute acid solutions when boiling. Solutions in acids are colourless, and show no absorption spectra. The emission spectrum of a solution in HClAq, obtained by help of the spark, shows several lines, the most conspicuous of which have the wave-lengths 6221, 5556, 5476, 5352, and 5334 (*v.* Lecoq de Boisbaudran, *C. R.* 88, 1342). S.G. 9·175. S.H. (0°–100°) ·0646 (Nilson, *l.c.*).

Hydrated ytterbium oxide. A white, gelatinous, but heavy pp. obtained by adding NH_3Aq to a solution of a salt of Yb; shrinks much when dried, and absorbs CO_2 from the air. Easily soluble in acids (Nilson, *l.c.*).

Ytterbium salts. Nilson (*l.c.*) prepared an oxalate, an acid selenite, and a sulphate; and Marignac (*C. R.* 87, 578) prepared a formate.

Ytterbium oxalate $Yb_2(C_2O_4)_3.10aq$. A white, microscopically crystalline powder; insoluble in water, scarcely soluble in dilute acids; unchanged in air; gives up part of its water at 100°. Prepared by adding oxalic acid to a warm solution of the sulphate.

Ytterbium selenite $Yb_2O_3.4SeO_2.5aq$. Obtained by adding Na_2SeO_3Aq to a solution of $Yb_2(SO_4)_3$, washing the ppd. normal selenite, dissolving in water containing a large excess of H_2SeO_3, evaporating nearly to dryness, and washing the residue with water. A white crystalline salt, insoluble in water. Loses $4H_2O$ at 100°.

Ytterbium sulphate $Yb_2(SO_4)_3$. Prepared by dissolving Yb_2O_3 in HNO_3Aq, adding H_2SO_4Aq, evaporating on a water-bath to drive off HNO_3, then on a sand-bath, and finally over a flame at low redness till all H_2SO_4 is removed. An opaque, white solid. Dissolves in water when a large quantity is added at once; if a little is added much heat is produced, the salt combines with the water, and then dissolves very slowly when more water is added. Decomposed at a red heat, fully at a white heat. S.G. 3·793. S.H. ·1039 at 0° to 100°.

A *hydrated sulphate* $Yb_2(SO_4)_3.8aq$ was obtained by Nilson in large, white, lustrous prisms by evaporating a solution of $Yb_2(SO_4)_3$ in water at a gentle heat.

M. M. P. M.

YTTRIUM. Y. At. w. c. 89·6. The name yttrium is given to the metal of an earth obtained from a few rare Swedish minerals. The separation of a new earth from a mineral found at Ytterby, in Sweden, was made by Gadolin in 1788. The existence of the new earth was confirmed in 1797 by Eckeberg, and the earth was called by him *yttria*. Subsequent researches carried on by Berzelius, Mosander, Scheerer, Berlin, Delafontaine, Popp, Bahr a, Bunsen, Marignac, and others showed that the yttria of Gadolin and Eckeberg was a mixture of many oxides (*cf.* ERBIUM, vol. ii. p. 456; SCANDIUM, vol.

iv. p. 401; Ytterbium, this vol. p. 879; and v. *infra*, *Homogeneity of Yttria*).

Occurrence.—About 30 to 35 p.c. of yttria, in combination with SiO_2, is found in the exceedingly rare Swedish mineral *gadolinite*; some specimens of *orthite* also contain yttria, and the earth has also been found, in combination with Nb_2O_5 and Ta_2O_5, in specimens of *euxenite*. The oxides that generally accompany yttria in these rare minerals are ceria, didymia, erbia, lanthana, lime, magnesia, soda, and oxide of iron.

Preparation of yttria.—The crude oxides of yttrium, erbium, &c., are separated from *gadolinite* by the method of Bahr a. Bunsen described under Erbium (vol. ii. p. 457). Marignac (*A. Ch.* [5] 14, 247) converted the oxides into nitrates, heated the nitrates in a Pt basin until red fumes came off freely; treated the residue with water, and separated the solution, which contained much Yt nitrate, from insoluble basic nitrates of Er, &c. He then evaporated the solution to dryness, heated again until partial decomposition was effected, again treated with water, poured off the solution, evaporated it to dryness, partially decomposed the solid nitrates by heat, and so on. After some hundred repetitions of these processes, approximately pure yttria was obtained. Auer von Welsbach (*M.* 4, 630) separated approximately pure yttria from the crude earths obtained from *gadolinite* by a long-continued series of operations based on the facts (1) that yttrium nitrate is less readily decomposed to basic salts than erbium nitrate when a fairly conc. solution of these nitrates is heated with the oxides of the metals made into a paste with water, and (2) that basic yttrium nitrates dissolve in a solution of the normal nitrates of Y and Er more readily than basic erbium nitrates.

References.—Gadolin (*Crell's Annal.* 1796 [1] 313); Eckeberg (*Scher. J.* 3, 187); Klaproth (*Scher. J.* 5, 531); Vauquelin (*Scher. J.* 5, 552); Berzelius (*Scher. J.* 16, 250, 404; and *Lehrbuch* [5th ed.], 2, 177); Berlin (*P.* 43, 105); Scheerer (*P.* 56, 483); Mosander (*P. M.* 23, 251); Popp (*A.* 131, 179); Delafontaine (*Ar. Sc.* [2] 21, 97; 22, 30; 25, 112; 51, 48; 61, 273); Bahr (*A.* 135, 376); Bahr a. Bunsen (*A.* 137, 1); Cleve a. Höglund (*Bl.* [2] 18, 193, 279); Cleve (*Bl.* [2] 21, 344).

Preparation of yttrium.—The metal has not been obtained pure. Wöhler in 1828 (*P.* 13, 580) obtained impure yttrium by reducing the chloride by sodium. In 1864 Popp (*A.* 131, 179) dissolved yttria in HClAq, added NH_4ClAq, evaporated, separated and dried the double chloride of yttrium and ammonium thus formed, mixed this with Na, the double salt and the Na being arranged in alternate layers, heated the mixture in a closed crucible till action began and then allowed the reaction to proceed; washed the fused mass with water, separated unreduced yttria by levigation, washed the dark-grey powder that remained with water, and then with alcohol, and dried it over H_2SO_4. In 1890 Winkler (*B.* 23, 787) obtained a black powder that decomposed water by heating yttria and finely-divided Mg in the ratio Y_2O_3:3Mg (*cf.* Yttria, p. 882). Popp describes yttrium as a dark-grey powder resembling *ferrum redactum*, decomposing cold water slowly and hot water rapidly, easily dissolved by dilute acids, including acetic acid, decomposing boiling KOHAq, and NH_4ClAq at the ordinary temperature, with evolution of H and NH_3; the metal burns brilliantly when heated on Pt foil; when heated in O it burns with a very dazzling light.

An examination of the emission spectrum of yttrium was made by Thalén: the most prominent lines observed had the wave-lengths 6191, 6131, 5987, 5971, 5662, 5496, 5402, 5205, 5200, 5088, 4900, 4881, 4854, 4374, and 4309 (*Kongl. Sv. Vetens. Acad. Handl.* 12).

The atomic weight of yttrium was determined by Berzelius, Delafontaine, Popp, Bunsen a. Bahr (*v. supra*, *References*) by analyses of the sulphate, or by transforming yttria into the sulphate; the values varied from 92·2 to 102·3. In 1873 Cleve a. Höglund (*v. B.* 6, 1467) made more accurate determinations by analysing purer specimens of $Yt_2(SO_4)_3$, and obtained the value 89·6.

Chemical relations of yttrium.—Assuming yttrium to be a homogeneous element with at. w. c. 89, it must be placed in Series 6 of Group III. in the periodic arrangement of the elements. This group contains the earth metals; yttrium is preceded in the even series family by B and Sc, and is succeeded by La and Yb. A consideration of the position given to Y in the periodic classification shows that the element ought to closely resemble the other metals of the earths. Too little is known of the properties of many of the earth metals to allow of a detailed comparison of them one with another. A general account of the relations of these metals will be found in Earths, metals of the (vol. ii. p. 424).

The homogeneity of yttria.—The properties described as belonging to yttria before 1885 were the properties of a mixture of at least five, and perhaps six, different bodies, according to Crookes (*C. N.* 54, 13, 155). Crookes subjected 'yttria' to a prolonged process of fractionation by ammonia (for a description of this method *v.* Earths, vol. ii. p. 423), and he then examined the phosphorescence spectra of various fractions. Crookes concludes that yttrium is a compound, or perhaps a very intimate mixture, of simpler bodies. For details of the phosphorescence spectra of the substances obtained by fractionating 'yttria' *v.* Metals, rare (vol. iii. p. 248). By thirty-two fractionations of 'yttria' by ppn. with NH_3Aq, followed by twenty-six fractionations by ppn. with oxalic acid, Lecoq de Boisbaudran (*C. R.* 103, 649 [1887]) obtained a white specimen of yttria which gave no phosphorescence spectrum when mixed with lime, and which, when converted into chloride, gave a spark spectrum, showing only the lines of yttrium.

Yttrium, bromide of, $YBr_3.9H_2O$. Colourless, very deliquescent tablets; obtained by dissolving Y_2O_3 in HBrAq and concentrating (Cleve, *Bl.* [2] 18, 193). The anhydrous salt is obtained by Duboin (*C. R.* 107, 99, 248) by heating Y_2O_3 to redness on a support of gas-carbon in a current of CO and Br vapour. Very soluble in water or alcohol; insoluble in ether.

Yttrium, chloride of, $YCl_3.6H_2O$. Obtained by dissolving yttria in HClAq, evaporating to dryness on a water-bath, dissolving in alcohol, and evaporating over H_2SO_4 (Cleve, *l.c.*). Crystallises in large, colourless, very deliquescent, rhombic prisms (C., *l.c.*). The anhydrous compound is formed by heating yttria to redness on a support of gas-carbon in a slow stream of CO and Cl (Duboin, *l.c.*). By evaporating a solution of yttria in HClAq with addition of NH_4Cl a *double compound* of YCl_3 and NH_4Cl is obtained; double compounds with KCl and NaCl are formed by fusing the constituent chlorides together. Popp (*A.* 131, 179) described the double compound $YCl_3.3HgCl_2.9H_2O$. Cleve (*Bl.* [2] 31, 195) described $YCl_3.SnCl_4.8H_2O$.

Yttrium, fluoride of, $2YF_3.H_2O$. Obtained as a gelatinous pp. by adding HFAq, or solution of an alkali fluoride, to solution of a salt of yttrium (Cleve, *Bl.* [2] 18, 193).

Yttrium, iodide of, (?YI_3). Deliquescent crystals, soluble in alcohol; obtained by evaporating a solution of yttria in HIAq (Berlin, *P.* 43, 105; no analyses given).

Yttrium, oxides of. Besides yttria, Y_2O_3, there probably exists another oxide containing more oxygen.

YTTRIA Y_2O_3. (*Yttrium sesquioxide.*) A *hydrate*, probably $Y_2O_3.6H_2O$ (Popp, *l.c.*), is obtained, as a gelatinous pp. closely resembling hydrated alumina, by ppg. the solution of a salt of yttrium by ammonia. The oxide is formed by strongly heating this hydrate; also by decomposing by heat the carbonate, nitrate, or oxalate of yttrium in presence of air. Yttria is described as a heavy, white or almost white powder, S.G. 5·078 (Cleve, *l.c.*); 5·046 (Nilson a. Pettersson, *B.* 13, 1459). S.H. (0°–100°) ·1026 (N. a. P., *l.c.*). By heating amorphous yttria with $CaCl_2$ for some hours, and washing with warm water, Duboin (*C. R.* 107, 99, 243) obtained highly refractive crystals of Y_2O_3, scarcely acted on by acids or by fused Na_2CO_3. Yttria is a markedly basic oxide; it absorbs CO_2 from the air, and decomposes solutions of ammonium salts, giving off NH_3. Yttria is insoluble in water; it dissolves slowly in cold HClAq, HNO_3Aq, or H_2SO_4Aq, but more rapidly on warming. By heating a mixture of yttria and finely-powdered Mg, in the ratio Y_2O_3:3Mg, Winkler (*B.* 23, 787) obtained a black powder which slowly gave off H from cold water, rapidly from hot water, and dissolved in dilute HClAq, with violent evolution of H.

YTTRIUM PEROXIDE. By adding H_2O_2Aq and NH_3Aq to a solution of sulphate or nitrate of yttrium, Cleve (*Bl.* [2] 43, 53) obtained a white gelatinous pp. to which he gave the composition Y_4O_9; but this formula cannot be regarded as final.

Yttrium, salts of. The salts which are formed by replacing the H of acids by yttrium belong to the form Y_2X_3, where X = $2ClO_3$, $2NO_3$, SO_3, SO_4, CO_3, $\frac{2}{3}PO_4$, &c. Almost all the yttrium salts of oxyacids that have been prepared are normal salts; a basic nitrate, and an acid orthophosphate and selenate, are known. Many of the salts are obtained by dissolving yttria in acids and evaporating; those salts which are insoluble, or but slightly soluble, in water are formed by ppn. from the nitrate or sulphate. The salts formed by ppn. are the *arsenate*, *borate*, *carbonate*, *chromate*, *iodate* and *periodate*, *oxalate*, *phosphates*, *selenite* and *sulphite*; besides these salts, the following salts of oxyacids are known, and are soluble in water: *bromate*, *chlorate* and *perchlorate*, *nitrate*, *selenate*, *sulphate*, *thiosulphate* and *tungstate*. A few *double salts* are known; the principal are $Y_2(CO_3)_3.M_2CO_3.xH_2O$,
$Y_2(C_2O_4)_3.3M_2C_2O_4.xH_2O$, and
$Y_2(SO_4)_3.mM_2SO_4.xH_2O$, where M = an alkali metal. Duboin (*C. R.* 107, 99, 243) obtained a *silicate* $Y_2O_3.SiO_2$ by very strongly heating a mixture of 3 pts. yttria with 30 pts. $CaCl_2$, and washing with water. The yttrium salts of oxyacids have been examined, chiefly by Cleve (*Bl.* [2] 18, 193, 289; 21, 344; *v.* also Berlin, *P.* 43, 105; Högbom, *Bl.* [2] 42, 2; Popp, *A.* 131, 179).

Yttrium, sulphide of. No compound of yttrium and sulphur has been isolated with certainty. Addition of $(NH_4)_2SAq$ or NH_4HSAq to a solution of a salt of yttrium ppts. hydrated oxide. By fusing yttria, S, and an alkali carbonate, and washing the fused mass with water, a yellowish-green solid is obtained that is insoluble in water, but is partly decomposed thereby to hydrated oxide and H_2S; this solid dissolves in acids, giving off H_2S. The same solid seems to be obtained by strongly heating yttria in H laden with CS_2. No compound of yttrium and S was obtained by heating yttria with Na_2S_5. By heating YCl_3 in a stream of H_2S, HCl is given off, and a yellow powder remains, which is decomposed by water, with evolution of much H_2S (*v.* Popp, *A.* 131, 179). According to Popp (*l.c.*), the composition of this substance is Y_2S_3.

By passing dry H_2S over a mixture of YCl_3 with excess of NaCl, heated to c. 1000° in a boat of gas-carbon, Duboin (*C. R.* 107, 99, 243) obtained a greenish, crystalline solid, which when washed with water left transparent, greenish lamellæ of the *double compound* $Y_2S_3.Na_2S$.

M. M. P. M.

ZANZALOÏN *v.* ALOÏN.

ZEORIN $C_{13}H_{22}O$. [231°]. Occurs in the ethereal extract from *Zeora sordida* (Paterno, *G.* 7, 281, 508). Small pyramids with hexagonal base (from ether-alcohol), v. sl. sol. alcohol and ether, insol. water. Neutral. Not attacked by alkalis or dilute acids.

ZINC. Zn. At. w. c. 65·3 (*v. infra*). Mol. w. c. 65·3 at c. 1400°; probably the same in solution in Hg (*v. infra*). Melts at 419° (determined by air thermometer; V. Meyer a. Riddle, *B.* 26, 2443); at 417·57° (determined by platinum thermometer, Callendar a. Griffiths, *C. N.* 63, 1); for older determinations, giving m.p. from 340° to 450°, *v.* Carnelley's *Melting- and Boiling-point Tables* (1, 14). Boils between 930° and 954° (Deville a. Troost, *C. R.* 90, 773); at 930° (Violle, *C. R.* 94, 720; *cf.* Troost, *C. R.* 94, 788). S.G. c. 6·9 to 7·2 (*v.* Schiff, *A.* 107, 59; Kalischer, *B.* 14, 2750; Quincke, *P.* 135, 642; Spring, *B.* 16, 2724). V.D. 34·8 at c. 1400° (Mensching a. V. Meyer, *B.* 19, 3295). S.H. (0° to 100°) ·0935 (Bunsen, *P.* 141, 1); (19° to 47°) ·0932 (Kopp, *T.* 155, 71; *cf.* Schüller a. Wartha, *B.* 8, 1016). C.E.; if length of bar at $0^\circ = l^\circ$, then length at $t^\circ = (1+\beta t)$; if volume at $0^\circ = V_0$, then volume at $t^\circ = (1+3\beta t)$; $\beta =$ ·00002976 from 0° to 100° (Matthiessen, *P. M.* [4] 32, 472). Heat of fusion for 1 kilo = 28,130 (Person, *A. Ch.* [3] 24, 129). T.C. (Ag = 100) 28·1 (Wiedemann, *P. M.* [4] 19, 243). E.C. (Hg at 0° = 1) 16·1 at 0°, 16·92 at 100° (Bénoit, *P. M.* [4] 45, 314); 14·83 at 15° (Kirchoff a. Hausemann, *W.* 13, 406). Chief lines in emission spectrum 6360, 6100, 4924, 4911, 4809, 4722, 4679 (Huggins, *T.* 154, 139; *cf.* Thálen, *Détermin. des Longueurs d'Onde des Raies Métalliques* [Upsala, 1868]; and Ames, *P. M.* [5] 30, 33); for wave-lengths of lines of high refrangibility *v.* Hartley a. Adeney (*T.* 1884 [1]. 97). Zinc crystallises in tabular hexagonal plates, $a : c = 1·356425$ (Williams a. Burton, *Am.* 11, 219; *cf.* Stolba, *J. pr.* 89, 122; 96, 178; Sharples, *Am. S.* [3] 7, 223; Nöggerath, *P.* 39, 324; Nicklès, *A. Ch.* [3] 22, 37; G. Rose, *B. B.* 1852. 26; *P.* 107, 448; Storer, *P. Am. A.* 6; Cooke, *Am. S.* 31, 191). The metal is probably dimorphous. H.C. [Zn,O] = 85,430 (Thomsen, *Th.* 3, 275). Refraction equivalent = 9·8 (Gladstone, *Pr.* 18, 49).

Historical.—That copper acquired a reddish colour, and that its properties were modified, by melting with certain ores, was known to the ancients and the alchemists; the ore with which copper was generally melted to form brass was called *cadmia fossilis*. The fact that a lustrous solid could be obtained by heating *cadmia fossilis* seems to have been known to the ancient writers on mineralogy. According to Kopp (*Geschichte der Chemie*, 4, 116), the earliest use of the word *zinc* is found in a writing of the fifteenth century attributed to Basil Valentine. Paracelsus, in the sixteenth century, speaks of zinc as a definite metal-like substance, and assigns it to the class of bastard or semi-metals. The name 'zinc' was applied during the seventeenth and eighteenth centuries alike to zinc ores and to the metal-like substance obtained from these ores. Boyle speaks of zinc, and also uses the word *spelter*, or *splauter*, a term of Indian origin according to Kopp. Tolerably pure zinc seems to have been obtained from zinc ores about 1720, probably by Henckel (*v.* Percy's *Metallurgy*, 1, 520).

Occurrence. — Zinc is found in small quantities; Becker (*J. M.* 1857, 698) and Phipon (*C. R.* 55, 218) noticed the occurrence of native zinc in Victoria. Considerable quantities of compounds of zinc occur in many places; the commonest ores are *calamine* (carbonate), *siliceous calamine* (silicate), *blende* (sulphide), and *red zinc ore* (oxide); aluminate, arsenate, phosphate, and sulphate of zinc are also found, but in smaller quantities. Small quantities of Cd compounds occur in most zinc ores. The ash of a plant that grows on the waste heaps of the zinc works in Rhenish Prussia (*Viola calaminaria*) is said to contain compounds of zinc (Braun; *P.* 92, 175). Zinc compounds have been found in some springs (*v.* Hillebrand, *U. S. Geolog. Survey Bull.* No. 113 [1898]). Traces of zinc compounds have been found, according to Lechartier a. Bellamy (*C. R.* 84, 687), in the human liver, in calves' liver, in beef, hens' eggs, wheat, barley, maize, beans, and vetches.

Formation.—Zinc ore, generally carbonate or sulphide, is roasted in reverberatory calciners; the roasted ore is mixed with half its weight of powdered charcoal, coke, or anthracite, and heated in crucibles or retorts arranged so that the reduced metal distils from the impurities; the metal is condensed and collected in suitable vessels, and CO passes off. For details and descriptions of the different forms of apparatus *v.* DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 1042.

Preparation.—Commercial zinc generally contains from ·5 to 3·3 p.c. lead, with c. ·2 to ·5 p.c. iron and cadmium, and small traces of arsenic.

Pure zinc was prepared by Reynolds a. Ramsay (*C. J.* 51, 854 [1887]) by dissolving zinc sold as free from common impurities in dilute H_2SO_4Aq, evaporating, crystallising the sulphate several times, electrolysing a solution of this salt, the metal being deposited on an electrode of Pt wire, dissolving the metal in dilute HClAq, ppg. ZnO_2H_2 by NH_3Aq, dissolving the pp. in excess of NH_3Aq, and ppg. ZnS by H_2S; the ZnS was dissolved in HClAq, and again ppd. from an ammoniacal solution by H_2S; the pp. was well washed, dissolved in pure dilute H_2SO_4Aq, and the sulphate obtained on crystallisation was re-crystallised several times; an aqueous solution of this sulphate was then electrolysed, using a Pt wire as electrode, and the metal was melted in a tube of hard glass from which the air had been exhausted. By distilling this metal *in vacuo* in a tube of hard glass, very pure zinc was obtained. Pullinger (*C. J.* 57, 816 [1890]) distilled zinc sold as 'chemically pure' in a hard glass tube, bent slightly towards the closed end, placed in a combustion furnace, the open end being connected with a good water-pump. By melting the distilled zinc in a tube of hard glass with a small bulb blown on the end, the part of the tube between the bulb and the wider portion containing the zinc being capillary, and the open end being connected with a water-pump, he obtained the zinc in perfectly bright, smooth, lustrous spheres free from hollows; the pump was stopped while the zinc was molten, and the increased pressure caused the molten metal to filter through the capillary tube into the bulb. For the preparation of pure zinc by electrolysis of an ammoniacal solution of the sulphate, *v.* Myers (*C. R.* 74, 195).

Stolba (*C. C.* 1884. 419) says that zinc can be obtained free from As and nearly free from iron by the combined interaction of S and water vapour. He mixes burnt gypsum with one-fourth its weight of S powder, moulds the moistened mixture into spheres about 5 cm. diameter, and sinks these to the bottom of a crucible containing molten zinc; vapours of

H_2S and S are given off, and the molten metal is thereby briskly agitated. When the reaction is completed, the little balls are taken out, the upper crust is removed, and the operation is repeated if necessary.

Zinc-dust is obtained either in the distillation of the metal, or, in not such fine division, by crushing and powdering the metal in an iron mortar at a temperature somewhat below the m.p. of zinc. The ZnO_2H_2 always present in specimens of zinc-dust may be removed by digesting with NH_4ClAq and then with NH_3Aq, and drying on a porous tile *in vacuo* (Carnegie, *C. J.* 53, 471).

Properties.—Zinc is a white metal, with a slight shade of blue; it is very lustrous when polished. Commercial zinc is brittle at the ordinary temperature, but it becomes malleable between 100° and 150°; at 210° it again becomes brittle, and at that temperature it can be finely powdered in a mortar. Pure zinc is said to be malleable at the ordinary temperature. Commercial zinc that has been heated to 100°-150° retains its malleability when it cools. Kahlischer (*B.* 14, 2747) noticed that rolled zinc ceased to give a ringing sound when struck after it was heated to c. 160°-300°, that it could then be bent easily, and that when bent it emitted a sound like the 'cry' of tin; he found that the zinc became crystalline, and the crystalline structure was more decided the higher the temperature; the S.G. was very slightly increased, and the electrical resistance was reduced by c. 3 p.c. Zinc is a softer metal than copper; its hardness is increased by rolling. The tensile strength of zinc varies much with the mode of preparation. Zinc crystallises easily, especially when pure; the form is that of hexagonal plates (for references *v. supra*, beginning of this article). Zinc melts at c. 420°, and boils somewhat below 1000° (*v. supra*). Molten zinc expands somewhat during solidification. The metal can be distilled at a full red heat; the vapour takes fire in the air, and burns with formation of ZnO and the production of a bright white light. Zinc exposed to the ordinary air becomes very gradually covered with a thin film of a basic carbonate which protects the mass of the metal from further corrosion; in pure dry air zinc is unchanged. Zinc dissolves in dilute acids, generally with evolution of H (*v. infra, Reactions with sulphuric and nitric acids*); it also dissolves in solutions of caustic potash or soda. When impure zinc is amalgamated it resists the action of acids. Zinc is not acted on by mineral lubricating oils; some of the commoner animal oils attack it slightly (*v.* Redwood, *C. S. I.* 5, 362). Zinc ppts. most of the other metals from their solutions; if a piece of impure zinc is dissolved in an acid, most of the metallic impurities (As, Cd, Cu, Pb, &c.) remain undissolved as long as undissolved zinc is present. Zinc combines directly with O, S, Se, Te, the halogens, and P; it forms alloys with many metals. Pure zinc does not decompose boiling water, but the commercial metal reacts and gives off H. Zinc-dust usually contains some ZnO_2H_2; it is said also to contain H, produced by the interaction of Zn and ZnO_2H_2 (*v.* Greville Williams, *C. N.* 52, 205, 268).

Atomic and molecular weights of zinc. In **1809 Gay-Lussac (*Mém. S. d'A.*, 2, 174)** determined the weight of ZnO obtained by dissolving a determinate weight of zinc in nitric acid, evaporating to dryness, and strongly heating the residue; Berzelius in 1811 repeated the experiment of Gay-Lussac (*G. A.* 37, 400; *v.* also *P.* 8, 184); and in 1843 Erdmann made similar experiments (*v. Berzelius' Lehrbuch*, 3, 1219). The values obtained for the at. w. of zinc were 65·39 (G.-L.), 65·41 (B.), and 64·94 and 64·88 (E.). In 1844 Favre decomposed ZnC_2O_4 by heating in air, and determined the weights of ZnO and CO_2 produced; the value 65·88 was thus obtained for the at. w. of zinc. In the same year Favre obtained the value 65·78 by dissolving zinc in dilute H_2SO_4Aq, burning the H given off by passing it over hot CuO, and weighing the water thus produced (*A. Ch.* [3] 10, 163). In 1884 Marignac determined the Cl and the Zn in $ZnCl_2.2KCl$, and obtained the value 65·18 for the at. w. of zinc (*A. Ch.* [6] 1, 309; *v.* also Baubigny, *C. R.* 97, 908 [1883]). By dissolving zinc in dilute H_2SO_4Aq and measuring the H given off, van der Plaats concluded that the at. w. of zinc is 65·18 (*C. R.* 100, 52 [1885]). Reynolds a. Ramsay, in 1887, by measuring the H given off by the interaction between very pure zinc and H_2SO_4Aq, obtained the value 65·48 (*C. J.* 51, 854). By oxidising zinc to ZnO, by HNO_3Aq, in 1888, Morse a. Burton obtained the value 65·1 (*Am.* 10, 311). In 1889 Gladstone a. Hibbert (*C. J.* 55, 443) determined the ratio of zinc dissolved to silver deposited by one and the same electric current; taking the at. w. of silver as 107·66 (the value adopted in this *Dictionary*) the at. w. of zinc was found to be 65·29.

In 1886 Mensching a. V. Meyer (*B.* 19, 3295) found the V.D. of zinc at c. 1400° to be 34·3, a number which shows that the gaseous molecule of zinc is monatomic. Ramsay, in 1889, determined the lowering of the vapour pressure of Hg produced by dissolving zinc therein (*C. J.* 55, 521); assuming that equal volumes of dilute solutions contain equal numbers of molecules, and that the molecular weight of liquid Hg is 200, Ramsay's results indicate that the molecules of zinc in dilute solutions of this metal in Hg are monatomic. The experiments of Heycock a. Neville (*C. J.* 57, 376 [1890], and 61, 888 [1892]) on the lowering of the freezing-points of Bi, Cd, Pb, Sn, and Na by solution of zinc in these metals tend to confirm the conclusion that the molecule of zinc in dilute solutions in these metals is monatomic.

Chemical relations of zinc. Zinc is the second odd-series member of Group II. in the periodic classification of the elements. Zinc is preceded in the odd series of this group by Mg and is followed by Cd, —, and Hg; the members of the even series of Group II. are Be, Ca, Sr, Ba, —, —. Zinc is the second member of series 5; it is preceded in this series by Cu, and is succeeded by Ga, Ge, As, Se, and Br. The general chemical character of zinc is that of a metal; its oxide ZnO is basic, its chloride $ZnCl_2$ is volatilisable without decomposition. No acids are known containing zinc, and the molecule of the element is monatomic. The fact that compounds of ZnO and K_2O are obtained by dissolving ZnO_2H_2 in KOHAq and adding alcohol shows that the hydroxide of the metal has feebly marked acidic properties, and the isolation of a number of oxychlorides and basic carbonates, nitrates, and sulphates illustrates the fact that zinc is less positive than Mg, which is the first member of the zinc family of Group II. For a general account of the properties of the family of which zinc forms a member *v.* MAGNESIUM GROUP OF ELEMENTS, vol. iii. p. 163. The atom of zinc is divalent in the gaseous molecules of its compounds.

Reactions and Combinations.—1. Zinc is unchanged in pure dry *air*; in ordinary air the surface layers are slowly converted into a basic carbonate, which protects the metal beneath. Heated strongly in air or *oxygen*, zinc burns to ZnO.—2. Heating zinc in *bromine*, *chlorine*, or *iodine* produces $ZnBr_2$, $ZnCl_2$, or ZnI_2.—3. When zinc is heated in *phosphorus* vapour, phosphide of zinc (*q. v.*, p. 890) is formed.—4. By heating zinc with *selenion* vapour, a compound of Zn and Se is formed (*v.* ZINC SELENIDE, p. 890).—5. Zinc combines with *tellurium* when the elements are heated together (*v.* ZINC TELLURIDE, p. 891).—6. *Sulphur* and zinc combine when a mixture of these elements is very strongly compressed (Spring, *B.* 16, 1000).—7. Zinc decomposes *water* at a red heat. Commercial samples of zinc decompose water at 100° (L'Hôte, *C. R.* 101, 1153).—8. ZnS is formed by strongly heating zinc in a stream of *hydrogen sulphide*; when *hydrogen selenide* is used the product is ZnSe, and by heating the metal in *hydrogen telluride* ZnTe is formed (*v.* Margottet, *C. R.* 84, 1293).—9. Zinc is said to reduce *carbon monoxide* at a very high temperature.—10. Zinc is superficially oxidised by heating to dull redness in *nitric oxide* (Sabatier a. Senderens, *C. R.* 114, 1429). Oxidation in *nitrogen dioxide* (NO_2) is effected at 300° (S. a. S., *C. R.* 115, 236).—11. Many *metallic oxides* are reduced by heating with zinc.—12. Zinc reacts with *sulphurous acid solution*; according to Schweizer (*v. C. N.* 23, 293), the products are $ZnSO_3$, along with $H_2S_2O_4Aq$, $H_2S_3O_6Aq$, and S.—13. Zinc dissolves in *hydrochloric acid*, giving off H and forming $ZnCl_2$. Reynolds a. Ramsay (*C. J.* 51, 857) say that pure zinc scarcely reacts with boiling hydrochloric acid. For reactions of zinc with sulphuric and nitric acids, *v. infra.*—14. Zinc dissolves slowly in hot solutions of *caustic soda* or *potash*, giving off H, and forming $ZnO.xM_2O$ (*cf.* ZINC HYDROXIDE, p. 888); the reaction is much hastened by adding iron or Pt along with the zinc.—15. Many *metallic salts in solution* are reduced by zinc, with ppn. of the metals, *e.g.* salts of As, Cd, Cu, and Pb.—16. When zinc-dust is shaken with an aqueous solution of *ferric chloride*, the whole of the ferric salt is very rapidly reduced to ferrous chloride (for details of the application of this reaction in the estimation of ferric iron, *v.* Carnegie, *C. J.* 53, 468 [1888]).—17. According to Siersch (*J.* 1867. 257), zinc dissolves in *sodium chloride* solution, forming $ZnCl_2.2NaClAq$, ZnO, and H.—18. Poumarède (*J. pr.* 73, 496) says that nearly all *chlorides* and *fluorides* are reduced by reacting with vapour of zinc in an atmosphere of H.—19. By heating to redness a mixture of zinc filings and *sodium metaphosphate*, Hvoslef (*A.* 100, 99) probably obtained phosphides of zinc (*v.* ZINC PHOSPHIDES, p. 890).—20. Zinc reacts with *sodium hydrogen sulphite* solution, forming $ZnSO_3$, $Na_2S_2O_4Aq$, and Na_2SO_3Aq (*v.* HYPOSULPHITES, this vol. p. 592).—21. By heating zinc with *zinc sulphide* in an exhausted tube, some of the ZnS is carried forward and deposited in the front part of the tube; probably at a high temperature ZnS is decomposed, and there exist only Zn and S, and at a lower temperature these recombine to form ZnS (Morse a. White, *Am.* 11, 348). A similar phenomenon is noticed on heating zinc with *zinc oxide* (M. a. W., *l.c.* p. 258).—22. ZnS is formed by strongly heating zinc and *mercuric sulphide* or zinc and *potassium polysulphides* (*v.* ZINC SULPHIDE, p. 890).

When slips of zinc-foil are immersed in $CuSO_4Aq$, a deposit of finely-divided Cu is formed on the zinc. This *copper-zinc couple* is an energetic reducing agent; $KClO_3Aq$ is reduced to KClAq, KNO_3Aq to KNO_2Aq and NH_3Aq, K_3FeCy_6Aq to K_4FeCy_6Aq, SO_2Aq to S, As_2O_3Aq to AsH_3, $C_6H_5NO_2$ (in alcohol) to $C_6H_5NH_2$, &c. (*v.* Gladstone a. Tribe, *C. J.* 33, 306).

Reactions of zinc with sulphuric and nitric acids. Commercial zinc dissolves easily in dilute H_2SO_4Aq, with formation of $ZnSO_4Aq$ and evolution of H. In 1830 De la Rive noticed that very little action took place between approximately pure zinc and H_2SO_4Aq; this fact has been confirmed by other experimentors. Reynolds a. Ramsay (*C. J.* 51, 857 [1887]) found that zinc prepared by repeated electrolysis of the sulphate and distillation *in vacuo* scarcely reacted with H_2SO_4Aq; L'Hôte (*C. R.* 101, 1153) also asserted that pure zinc does not react with H_2SO_4Aq. Divers a. Shimidzu (*C. J.* 47, 598 [1885]) observed very great differences between the rate of action of the same H_2SO_4Aq on sheets of commercial zinc of the same size. Pullinger in 1890 (*C. J.* 57, 815), and Weeren in 1891 (*B.* 24, 1785), made somewhat elaborate investigations into the connections between the conditions and the rate of the interaction of zinc and H_2SO_4Aq.

Pullinger used 'pure' sulphuric acid diluted with three times its weight of water; and zinc prepared by distilling that sold as 'chemically pure' *in vacuo* and casting in balls under pressure to prevent the formation of cracks or hollows (*v. supra, Preparation of zinc*, p. 885). He found that when the surface of the zinc was very smooth this was best accomplished by immersing in *aqua regia* for 10 or 15 seconds, and washing with water—and the acid was boiled for some hours before the experiment, there was practically no reaction at 20°–25° (spheres of zinc weighing c. 2½ g. lost from 5 to 6 mgms. in 20 hours). Pullinger found that the presence of small quantities of H_2S, SO_2, or H_2S_2[illegible]Aq did not affect the weight of zinc dissolved by the boiled H_2SO_4Aq; addition of some H_2O_2 materially increased the rate of action; and H_2SO_4Aq that had been electrolysed before use dissolved from four to ten times more zinc than some of the same acid that had not been electrolysed; addition of a few drops of HNO_3Aq considerably increased the action; when a few drops of HIAq were added to the H_2SO_4Aq practically no action occurred. P. supposed that all the 'pure' acid used by him contained traces of an oxidising substance, probably $H_2S_2O_8$, and that the solvent action was due to this. P.

insists on the important connection between the rate of action and the smoothness or roughness of the surface of the zinc used. But he concludes that 'in all probability *pure* dilute sulphuric acid would, at ordinary temperatures, be entirely without action upon metallic zinc, whether the surface of the latter were rough or smooth.'

Weeren used zinc which he found to be chemically pure by analysis; he gives no account of his method of preparation nor any details of his analytical results. W. found that the weight of pure zinc dissolved by pure H_2SO_4Aq (1:20) at the ordinary temperature, and under a pressure of 10 mm., was c. ten times greater than the weight dissolved at 760 mm. pressure; but the weights of impure zinc dissolved at the two pressures were almost the same. The pure zinc used by W. dissolved fairly rapidly in boiling H_2SO_4Aq; in one case when 2·1 mgm. dissolved at 0° after thirty minutes' action, 122 mgm. dissolved in the boiling acid. W. found that the solubility of his pure zinc increased very slowly as temperature rose up to within 1° of the b.p. of the acid used, but that when ebullition actually began the solubility of the zinc suddenly increased; the weight of pure zinc dissolved by H_2SO_4Aq at 100° and boiling, was c. sixteen times greater than the weight of the same zinc dissolved by the same acid at 100° but kept from actually boiling by pressure. On the other hand, W. noticed that as much impure zinc dissolved at 100° when the acid was boiling as when it was prevented by pressure from boiling. Addition of oxidisers, CrO_3 or H_2O_2, enormously increased (c. 300 times) the solubility of pure zinc in H_2SO_4Aq at 18°-20°, but only slightly increased (c. six times) the solubility of impure zinc. W. supposes that when pure zinc is immersed in pure H_2SO_4Aq a slight reaction occurs, and that the H produced is attracted to and held firmly on the surface of the zinc, and that the reaction ceases because the surface of the metal is protected by the layer of H. Increase of temperature does not appreciably affect the rate of action, because the layer of H remains fixed to the surface of the zinc, but when the acid boils the H is removed and rapid dissolution occurs; any conditions which remove the layer of H increase the solubility of the zinc. W. supposes that the rate of dissolution of impure zinc in H_2SO_4Aq is not much affected by boiling, presence of oxidisers, &c., because H is not given off at the surface of the zinc, but at the surface of the more negative impurities. The rapid solution of zinc in HNO_3Aq is connected, according to W., with the rapid oxidation of the H produced at the surface of the zinc, and hence the production of a layer of water on the surface of the metal which destroys the attraction between the zinc and any H that may escape oxidation.

As regards the products of the interaction of zinc and sulphuric acid, when the acid is fairly concentrated (c. $H_2SO_4.H_2O$ to c. H_2SO_4) SO_2 is given off, and at moderately high temperatures H_2S and S are also produced (*v.* Calvert a. Johnson, *C. J.* [2] 4, 435 [1867]). A qualitative examination of the products by Pattison Muir a. Adie (*C. J.* 53, 47 [1888]) showed that $ZnSO_4$ is the only salt of zinc produced, with any concentration of acid, and at any temperature up to the b.p. of the acid used; that with approximately pure zinc little or no SO_2 or H_2S is formed unless the temperature be high; and that the purer the zinc the less is the quantity of S produced (*cf.* Ditte, *A. Ch.* [6] 19, 68).

The products of the interaction of zinc and nitric acid are $Zn(NO_3)_2Aq$, $Zn(NO_2)_2Aq$, NH_4NO_3Aq and NH_4NO_2Aq, and NO, N_2O, and N. Acworth found that when HNO_3Aq reacts with zinc in presence of $(NH_4)NO_3$ the chief gaseous product is N (along with some N_2O and NO) (*C. J.* 28, 828 [1875]). Acworth a. Armstrong studied the reaction of HNO_3Aq and Zn more fully in 1878 (*C. J.* 32, 54), and found that the only gaseous products were N, N_2O, and NO (*cf.* Deville, *C. R.* 70, 22, 550 [1870]). According to Divers (*C. J.* 43, 443 [1883]), a little NH_2OH is formed when cold HNO_3Aq (3 to 4 p.c.) is poured on to granulated zinc and quickly poured off again. Divers a. Shimidzu (*C. J.* 47, 597 [1885]) found that considerable quantities of NH_2OH are produced by the combined reaction of HNO_3Aq and H_2SO_4Aq, or HNO_3Aq and HClAq, on zinc (*v.* HYDROXYLAMINE, *Formation*, vol. ii. p. 734). Divers (*l.c.*) thought that zinc does not form $Zn(NO_2)_2$ by a direct reaction with HNO_3Aq, but by interacting with some of the $Zn(NO_3)_2$ formed by the primary action of the metal on the acid. The products of the interaction of zinc and HNO_3Aq have been examined recently by Montemartini (*G.* 22 [1], 277 [1892]), who says that free H is not produced (he also says that no NH_2OH is formed), and that in addition to nitrate and nitrite of zinc and ammonium, hyponitrite is also produced; the gaseous products, according to M., are N_2O, NO, NO_2, and N; there is no nitrous acid formed, says M., if the HNO_3Aq contains more than 30 p.c. HNO_3, and no NO_2 if less than 30 p.c. HNO_3 is present. M. also gives determinations of the quantities of the various products at different temperatures, and of the rate of reaction with different concentrations of HNO_3Aq (*Abstract* in *C. J.* 62, 1279 [1892]).

Zinc, alloys of. Alloys of zinc have been formed with most metals by fusing the constituents together; the alloys are generally hard, some of them are brittle. With *antimony*, two crystalline alloys are formed by melting the metals together, in the ratios 3Zn:2Sb and Zn:Sb, and allowing to cool very slowly; Cooke (*Am. S.* [2] 18, 229; 20, 222) formulates these alloys as Zn_3Sb_2 and Zn_2Sb_2 respectively. These alloys react with water and give off H. Alloys with *arsenic* are formed by heating together Zn and As, or Zn and As_2O_3, or by heating Zn in vapour of As and H; by the last method Descamps (*C. R.* 86, 1022, 1065) obtained crystals agreeing in composition with the formula Zn_3As_2. Spring (*B.* 16, 324) formed an alloy by compressing Zn and As, in the ratio 3Zn:2As, at 6,500 atmospheres. Zinc alloys with *bismuth* when the metals are melted together, but on cooling two layers are formed, the upper containing zinc with c. 2 p.c. Bi, and the lower Bi with from 8 to 14 p.c. zinc. An alloy of zinc with *bismuth and lead* (3 pts. Zn, 5 pts. Bi, and 5 pts. Pb) melts at 94·5°. For descriptions of alloys with *calcium* *v.* Caron (*C. R.* 48, 440; 50, 547); Wöhler (*A.* 138, 253); and Norton a. Twitchell

(*Am. J.* 10, 70). *Brass* is composed of alloys of zinc with *copper* (*v.* vol. ii. p. 254; and for details *v.* DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 1052). Alloys of zinc with *copper and nickel* form *German silver*; most modern *bronzes* are alloys of zinc with *copper and tin* (*v.* vol. ii. p. 254; and for details *v.* DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 838). Zinc alloys with *iron* (for details *v.* DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 1051). For alloys with *lead v.* vol. iii. p. 125 (also Krant, *S. C. I.* 5, 537). Alloys with *lead and tin* are mentioned in vol. iii. p. 125 (*v.* also Wright a. Thompson, *Pr.* 48, 25). For alloys with *magnesium v.* Parkinson (*J. pr.* 101, 375). Zinc and *mercury* form a number of amalgams, which are brittle when a little Hg is present and pasty when much Hg is present (for references *v. S. C. I.* 9, 512). For alloys with *platinum v.* this vol. p. 288. For alloys with *silver v.* Wright a. Thompson (*Pr.* 48, 25).

For an account of the formation of zinc alloys by immersing zinc in various metallic solutions *v.* Mylius a. Fromm (*B.* 27, 630 [1894]).

Zinc, amide of, $Zn(NH_2)_2$. This compound was obtained by Frankland (*Pr.* 8, 502) by passing dry NH_3 into an ethereal solution of $ZnEt_2$. A white, amorphous powder; unchanged at 200°, but decomposed at a red heat to Zn_3N_2 (*v.* ZINC NITRIDE, p. 889) and NH_3; reacts with water to form ZnO_2H_2 and NH_3.

Zinc, bromide of, $ZnBr_2$. Formula probably molecular, from analogy of $ZnCl_2$. S.G. 3·643 at 10° (Bödeker). Melts at 394° (Carnelley, *C. J.* 33, 277). Boils at 695° to 699° (C. a. Williams, *C. J.* 33, 283); at 650° (Freyer a. V. Meyer, *B.* 25, 622). H.F. $[Zn,Br^2] = 75{,}930$ (*Th.* 3, 275).

Preparation.—1. Zinc filings are heated to dull redness in a stream of Br vapour.—2. Zinc, or ZnO_2H_2, is dissolved in a slight excess of HBrAq, the solution is evaporated to dryness, and the dry residue is sublimed out of contact with air.

Properties and Reactions.—White needles; very deliquescent. Easily soluble in water, alcohol, or ether (*v.* Berthemot, *J. Ph.* 14, 610). Thomsen gives $[ZnBr^2,Aq] = 15{,}030$ (*Th.* 3, 275). Aqueous solutions of $ZnBr_2$ of different concentrations have the following specific gravities according to Kremers (*P.* 108, 115):—

S.G. $ZnBr_2Aq$ at 19·5°.	P.c. $ZnBr_2$.
1·1849	18·3
1·3519	31·7
1·5276	43·2
1·7082	52·6
1·8525	59·1
2·1027	68·0

Combinations.—1. With *ammonia* to form a series of compounds. These compounds were examined by Rammelsberg (*P.* 55, 240), and, more recently, by André (*Bl.* [2] 39, 398 [1883]). By dissolving $ZnBr_2$ in NH_3Aq under different conditions, A. obtained (1) $ZnBr_2.2NH_3.H_2O$, (2) $3ZnBr_2.8NH_3.2H_2O$, (3) $3ZnBr_2.10NH_3.H_2O$, and (4) $ZnBr_2.5NH_3$; by saturating hot NH_4BrAq with ZnO, he obtained $3ZnBr_2.6NH_3.H_2O$.—2. With *cæsium bromide*, to form $ZnBr_2.3CsBr$ and $ZnBr_2.2CsBr$ (Wells a. Campbell, *Zeit. f. anorg. Chemie*, 5, 273).

Zinc, chloride of, $ZnCl_2$. Mol. w. c. 136. Melts at 262° (Braun, *P.* 154, 190). Boils at 708°–719° (Carnelley a. Williams, *C. J.* 33, 284); at 730° (Freyer a. V. Meyer, *B.* 25, 622). S.G. 2·753 at 13° (Bödeker). V.D. at 890° to 907° = 66 (F. a. M., *l.c.*). H.F. $[Zn,Cl^2] = 97{,}210$ (*Th.* 3, 275).

Formation.—1. By heating zinc filings in Cl.—2. By heating a mixture of 2 pts. $HgCl_2$ and 1 pt. zinc filings in a retort.—3. By distilling a mixture of equal pts. $ZnSO_4$ and $CaCl_2$, or a mixture of 1 pt. ZnO and 2 pts. NH_4Cl.—4. By dissolving zinc, or ZnO_2H_2, in HClAq, evaporating to dryness, and heating the residue in a retort.

Preparation.—1. Zinc filings are heated in a small retort in a stream of Cl; the product is distilled.—2. Zinc, or ZnO_2H_2, is dissolved in a slight excess of HClAq; the solution is evaporated to dryness, and the residue is distilled from a small retort.

Properties and Reactions.—A white, semi-transparent, crystalline, very caustic solid; very deliquescent. Easily soluble in water, also in alcohol. Thomsen gives $[ZnCl^2,Aq] = 15{,}630$ (*Th.* 3, 275). Sublimes at a red heat. An aqueous solution is partly decomposed on evaporation, giving oxychlorides (*q.v.*). Oxychlorides are also formed by heating a solution of $ZnCl_2$ in HClAq with ZnO, also with HgO or PbO. Kremers (*P.* 105, 360) gives the following data:

S.G. $ZnCl_2Aq$	P.c. $ZnCl_2$
1·1275	13·8
1·2466	25·8
1·3869	37·5
1·5551	49·2

A conc. solution of $ZnCl_2$ is often used as a bath for maintaining fairly high constant temperatures. Dry $ZnCl_2$ is used as a caustic; also as a dehydrating agent; a dilute aqueous solution is employed as an antiseptic.

Combinations.—1. With *water*. By keeping $ZnCl_2Aq$ containing 70·5 p.c. $ZnCl_2$ at 0° for 24 hours, Engel (*C. R.* 102, 111) obtained large crystals of the *trihydrate*, $ZnCl_2.3H_2O$, melting at 7°. When $ZnCl_2Aq$ containing 79·9 p.c. $ZnCl_2$ at 0° is kept for a long time it solidifies; on heating to 16° a part melts and a part remains solid; the liquid part is the *dihydrate* $ZnCl_2.2H_2O$, and the solid part is the hydrate $2ZnCl_2.3H_2O$ (E., *l.c.*). By heating a syrupy solution of $ZnCl_2$ with a little HClAq, Schindler (*Mag. Pharm.* 36, 45) obtained octahedral crystals of the *monohydrate* $ZnCl_2.H_2O$. According to Engel (*l.c.*), the hydrate obtained by S. was $2ZnCl_2.3H_2O$.—2. With *hydrogen chloride and water*. Engel (*M.* 5, 432) obtained the compounds $2ZnCl_2.HCl.2H_2O$ and $ZnCl_2.HCl.2H_2O$ by passing HCl gas into $ZnCl_2Aq$, and adding zinc from time to time, and, when the solution had the S.G. of 2·0, cooling to 0°.—3. Various compounds of $ZnCl_2$ with *ammonia* have been described; the formulæ $ZnCl_2.NH_3$, $ZnCl_2.2NH_3$, $2(ZnCl_2.2NH_3).H_2O$, $ZnCl_2.4NH_3.H_2O$, and $ZnCl_2.5NH_3.H_2O$ have been given to compounds obtained by dissolving $ZnCl_2$ in NH_3Aq, passing in NH_3, and evaporating under different conditions (*v.* Marignac, *Ann. M.* [5] 12, 1; Divers, *C. N.* 18, 13; Priwoznik, *P.* 142, 467; Davis, *C. N.* 25, 265; André, *A. Ch.* [6] 3, 84, 98; Thoms, *B.* 20, 743).—4. Lang (*B.* 21, 1578) described a compound with *pyridine*, $ZnCl_2.2C_5H_5N$.—5. $ZnCl_2$ combines with *alkali chlorides*. Compounds, $ZnCl_2.NH_4Cl.xH_2O$, $ZnCl_2.2NH_4Cl.xH_2O$, and $ZnCl_2.3NH_4Cl$ are described by Schindler (*Mag. Pharm.* 36, 45), Marignac (*J.* 1857. 217), Rammelsberg (*P.* 94, 508), and Hantz (*A.* 66, 287). A compound $ZnCl_2.2KCl$ is described by R. (*l.c.*) and M. (*l.c.*); and a compound $ZnCl_2.2NaCl.3H_2O$ by M. (*l.c.*). Wells a. Campbell (*Zeit. f. anorg. Chemie*, 5, 273) describe two compounds with CsCl, to which they give the formulæ $ZnCl_2.2CsCl$ and $ZnCl_2.3CsCl$.—6. With *zinc oxide*, *v. Oxychlorides*, p. 891.

A solution of zinc in conc. KClAq, to which as much NH_4Cl has been added as the weight of zinc dissolved, is used for cleaning the surfaces of metals that are to be soldered together; any oxide on the metallic surfaces reacts with the NH_4Cl present to form chloride which dissolves in the $ZnCl_2$ solution.

Zinc, cyanide of, and double zinc cyanides; *v.* vol. ii. p. 347. For details regarding the conditions of formation and the properties of *zinc-mercuric cyanide*, *v.* Dunstan, *C. J.* 61, 666 [1892].

Zinc, ferrocyanide of; *v.* vol. ii. p. 337.

Zinc, fluoride of, ZnF_2. Formula probably molecular, from analogy of $ZnCl_2$. Formed by heating zinc or ZnO to redness in a stream of dry HF; also by the interaction of fused $ZnCl_2$ and dry HF at 800° to 900°; also by heating the hydrated salt to redness in dry HF (Poulenc, *C. R.* 116, 581 [1893]). The *tetrahydrate* $ZnF_2.4H_2O$ is obtained by evaporating a solution of zinc in HFAq, and crystallising. The salt ZnF_2 crystallises in colourless needles, probably monoclinic. S.G. 4·84 at 15°; the crystals act strongly on polarised light (P., *l.c.*). Clarke (*Am. S.* [3] 13, 291) gives S.G. of ZnF_2 as 4·556 at 17°, and 4·612 at 12°; and the S.G. of $ZnF_2.4H_2O$ as 2·567 at 10° and 2·535 at 12°. ZnF_2 is slightly soluble in cold, more soluble in hot, water; it is insoluble in alcohol at 95°; soluble in boiling HClAq, H_2SO_4Aq, or HNO_3Aq (P., *l.c.*). Heated in air, or to redness in steam, it is wholly changed to ZnO; fusion with alkali carbonates produces ZnO and alkali fluorides; heating with H_2S forms ZnS, and with HCl forms $ZnCl_2$. It is reduced by H at a red heat (P., *l.c.*). ZnF_2 forms *double salts* with AlF_3 and with alkali fluorides. Berzelius (*P.* 1, 26) described the salts $ZnF_2.2AlF_3$ and $ZnF_2.2KF$; and Wagner (*B.* 19, 896) the salts $ZnF_2.2NH_4F.2aq$, $ZnF_2.KF$, and $ZnF_2.NaF$. The compound $ZnF_2.ZrF_4.6aq$ ($= ZnZrF_6.6aq$) is described by Marignac (*A. Ch.* [3] 60, 257); S.G. 2·255 at 12° (Topsöe, *C. C.* 4, 76). For $ZnF_2.SiF_4$ *v.* ZINC SILICOFLUORIDE, p. 890.

Zinc, hydrophosphide of, ZnPH. A white, friable solid having this composition was obtained by Drechsel a. Finkelstein (*B.* 4, 352) by passing dry PH_3 into a cooled ethereal solution of $ZnEt_2$. The compound can be kept in a closed vessel; in air it absorbs moisture and rapidly decomposes, giving off PH_3.

Zinc, hydrosulphide of. According to Thomsen (*B.* 11, 2044 [1878]), the pp. obtained by mixing NaHSAq and $ZnSO_4Aq$, in equivalent quantities, is probably a hydrosulphide of zinc (no analyses or formula given). Addition of two equivalents of NaSH in solution to an equivalent of $ZnSO_4$ in solution produces no pp., but the solution gives a pp. of ZnS or hydrosulphide on standing, or on addition of acid or soda (T., *l.c.*). According to von Zotta (*M.* 10, 807 [1890]), the pp. supposed by Thomsen to be zinc hydrosulphide has the composition $ZnS_2H_2.2ZnS$. When four equivalents of NaSH are added to one equivalent of $ZnSO_4$, both in solution, and the clear solution is boiled, or treated with acid or alkali, a pp. of $ZnS_2H_2.2ZnS$ is obtained (von Z., *l.c*). Linder a. Picton (*C. J.* 61, 130 [1892] obtained evidence in favour of the existence of compounds of Zn, S, and H, probably $7ZnS.H_2S$ and $12ZnS.H_2S$, by passing H_2S into water at 0° with ZnO_2H_2 in suspension; they failed to isolate a definite compound with certainty.

Zinc, hydroxide of, ZnO_2H_2. (*Zinc hydrate. Hydrated zinc oxide.*) Obtained, as a white flocculent pp., by adding to solution of a salt of zinc rather less KOHAq than is sufficient to decompose the whole of the salt, washing thoroughly, and drying at a low temperature. According to Ville (*C. R.* 101, 375), ZnO_2H_2 is obtained in crystals by shaking very finely-powdered $ZnCO_3$, or basic carbonate, with twice as much KOH in 10 p.c. solution as is theoretically required for the decomposition of the carbonate; formation of crystals of ZnO_2H_2 begins at once, and is complete after twenty to thirty minutes. ZnO_2H_2 is said to be obtained in lustrous rhombic prisms by immersing zinc in contact with iron or copper in NH_3Aq (Nicklès, *A. Ch.* [3] 22, 31; Cornu, *Bl.* 5, 64 [1863]). Bödeker (*A.* 94. 358) obtained the *monohydrated hydroxide* $ZnO_2H_2.H_2O$ in very lustrous octahedra by keeping a saturated solution of the hydroxide in NaOHAq in a closed vessel for some weeks. S.G. of ZnO_2H_2 is given by Nicklès (*l.c.*) as 2·677, and by Filhol (*A. Ch.* [3] 21, 415) as 3·053. Thomsen gives $[Zn,O,H^2O] = 82,680$ (*Th.* 3, 275). ZnO_2H_2 dissolves easily in acids, forming salts ZnX^I_2.

ZnO_2H_2 also dissolves in caustic alkali solutions, and in $(NH_4)_2CO_3Aq$. By adding alcohol to a solution of ZnO_2H_2 in KOHAq, Laux (*A.* 9, 183) obtained small lustrous crystals (?ZnO_2K_2); Fremy (*C. R.* 15, 1106) obtained (?) $ZnO_2K_2.ZnO$; by using NaOHAq Comey a. Jackson (*B.* 21, 1589 [1888]) obtained two compounds derived from ZnO_2H_2 by replacing H by Na. They shook a solution of ZnO_2H_2 in conc. NaOHAq with alcohol, separated the upper (alcoholic) layer and allowed it to crystallise, and treated the lower (watery) layer repeatedly with alcohol until it solidified. The crystals from the lower layer had the composition

$$Zn_3O_6Na_4H_2.17H_2O\ (= Zn_3(OH)_2(ONa)_4.17H_2O),$$

agreeing, except in water of crystallisation, with an ammonium compound described by Malaguti (*C. R.* 62, 413 [1866]); this compound melts at c. 70°, rapidly absorbs CO_2 from the air, loses $12H_2O$ at 100°, is insol. in ether, and is decomposed by water, but not in presence of excess of NaOH, with formation of ZnO and a little ZnO_2H_2. The crystals from the upper layer had the composition

$$2ZnO_2NaH.7H_2O = (2Zn(OH)(ONa).7H_2O),$$

corresponding with the compound described by Fremy (*l.c.*); this compound forms white radiating needles, which do not melt at 300°; it absorbs CO_2 from the air more slowly than the other compound, is decomposed by alcohol or water, and does not lose H_2O until heated above 200° (*v. Am.* 11, 145 [1889]). C. a. J. failed to obtain compounds derived from ZnO_2H_2 by replacing H by NH_4 or Mg. Compounds of ZnO with BaO, CaO, and MgO are described by Bertrand (*C. R.* 115, 939); these compounds are of the forms $2ZnO.MO.xH_2O$.

Zinc, iodide of, ZnI_2. Formula probably molecular, from analogy of $ZnCl_2$. Formed by heating together zinc and iodine, and subliming; also by digesting I with water and excess of zinc until the liquid is colourless and evaporating over H_2SO_4 (Rammelsberg, *P.* 43, 665). Crystallises in white octahedra; S.G. 4·696 (Bödeker); melts at c. 446° (Carnelley, *C. J.* 33, 278); and boils at c. 624° (C. a. Williams, *v.* Carnelley's *Melting- and Boiling-point Tables,* 1, 23). H.F. $(Zn,I^2) = 49,230$; $[Zn,I^2,Aq] = 60,540$ (*Th.* 3, 275). Heated in air ZnI_2 gives off I, and ZnO remains. Kremers (*P.* 111, 61) gives the following data:—

S.G. ZnI_2Aq	P.c. ZnI_2	S.G. ZnI_2Aq	P.c. ZnI_2
1·2340	23·1	1·9746	63·5
1·5121	42·6	2·3976	76·0
1·7871	56·3		

Hot ZnI_2Aq is said to dissolve zinc in contact with the air, and on filtering an oxyiodide is said to be deposited (Müller, *J. pr.* 26, 441). ZnI_2Aq also dissolves I; Baup (*J. Ph.* 9, 37 [1823]) says enough I is dissolved to form ZnI_4.

ZnI_2 combines with NH_3. By allowing a solution of ZnI_2 in NH_3Aq to evaporate, Rammelsberg (*P.* 48, 152) obtained lustrous, four-sided prisms of $ZnI_2.4NH_3$, decomposed by water with production of ZnO. Various *double compounds* with other iodides have been described: $ZnI_2.2MI$, where $M = NH_4$, K or Na (Rammelsberg, *l.c.*; also *P.* 43, 665); $ZnI_2.2CsI$ and $ZnI_2.3CsI$ (Wells a. Campbell, *Zeit. f. anorg. Chemie,* 5, 273); $2ZnI_2.BaI_2$ (R., *l.c.*); $ZnI_2.2BiI_3.12aq$ (Linau, *P.* 111, 240).

Zinc, nitride of, Zn_3N_2. Obtained by Frankland (*Pr.* 8, 502) by heating zinc amide ($Zn(NH_2)_2$; *v.* p. 887) to low redness. A grey, pulverulent solid; unchanged by heating to redness out of contact with air; reacts violently with water to give ZnO_2H_2 and NH_3.

Zinc, nitroprusside of, *v.* vol. ii. p. 341.

Zinc, oxides of. Besides the normal basic oxide ZnO, there seems to be another higher (? superoxide) of zinc.

ZINC OXIDE ZnO. Formula not certainly molecular.

Occurrence.—With oxides of Mn, and Fe, as *red zinc ore* and *franklinite.*

Formation.—1. By burning zinc in air or O. 2. By strongly heating ZnO_2H_2, $Zn(NO_3)_2$, $ZnCO_3$, or another salt of zinc with a volatilisable acid.

Preparation.—Pure $ZnSO_4$, prepared as described under Zinc, *Preparation* (p. 883), is dissolved in water, and the solution is *very slowly* added to a boiling solution of pure Na_2CO_3 containing rather less Na_2CO_3 than suffices to decompose all the $ZnSO_4$. The pp. of basic zinc carbonate is washed by decantation with boiling water until the washings are free from carbonates and sulphates; it is then dried, powdered, and heated either in a Hessian crucible, or, better, in a flask of hard glass, until a portion taken from the middle dissolves, when cold, in acid without effervescence. The solid is now finely powdered, sifted through a fine sieve, again heated and then rubbed up with water, and washed and dried. ZnO is prepared in crystals by heating $ZnCl_2$ to redness in steam (Daubrée, *C. R.* 39, 153); also by heating the amorphous oxide slowly in a stream of H (Regnault, *A. Ch.* [2] 62, 350; Deville, *A. Ch.* [3] 43, 477); also by heating the amorphous oxide to whiteness in a stream of O (Sidot, *C. R.* 69, 202); also by heating $Zn(NO_3)_2$ to redness (Brügelmann, *W.* 4, 283).

Properties.—A slightly yellow, powdery solid; becomes darker yellow when heated, but recovers its original colour on cooling. S.G. 5·5 to 5·7 (*v.* Brügelmann, *B.* 13, 1741; Filhol, *A. Ch.* [3] 21, 415; Herapath, *C. J.* 1, 42; Karsten, *S.* 65, 394). S.G. crystalline (at 15°) 5·782 (Brügelmann, *W.* 4, 286). ZnO crystallises in slightly yellow, lustrous, hemimorphous pyramids belonging to the hexagonal system (B., *l.c.*). Thomsen (*Th.* 3, 275) gives H.F. $[Zn,O] = 85,430$. Richards a. Rogers (*Am.* 15, 567 [1893]) found that ZnO, prepared by heating $Zn(NO_3)_2$, gave off some gas when dissolved in dilute acids; the maximum amount of gas from 10 g. ZnO was 20 c.c.; the gas consisted chiefly of N, with a little O; the higher the temperature to which the $Zn(NO_3)_2$ had been heated the less was the quantity of gas obtained; but some N always came off, even from ZnO which had been heated to the softening temperature of porcelain. Moissan (*C. R.* 115, 1034 [1892]) states that ZnO volatilises readily when heated in an electric furnace, and condenses again in transparent crystals. ZnO is not decomposed at c. 1750° (Read, *C. J.* 65, 313 [1894]).

Reactions and Combinations.—1. ZnO is a basic oxide. It interacts with most *acids* to form salts $ZnX(X = 2NO_3, SO_4, \frac{2}{3}PO_4$, &c.) and water.—2. With fairly conc. *caustic soda* or *potash*, salts are formed which are most simply regarded as derived from ZnO_2H_2, with H replaced by Na or K (*v.* ZINC HYDROXIDE, p. 888).—3. ZnO is reduced to Zn, with explosive violence, by heating with *magnesium* (*v.* Winkler, *B.* 23, 123).—4. Morse a. White (*Am.* 11, 258) heated a mixture of ZnO and *zinc* in an exhausted tube, and found that a deposit of ZnO formed in the front part of the tube. They suppose that some of the original ZnO is decomposed by the combined action of heat and zinc, and that zinc and O exist together in the hot part of the tube, but combine in the cooler parts of the tube to form ZnO.—5. Oxychlorides, oxybromides, and probably oxyiodides of zinc are formed by heating ZnO with *zinc chloride, bromide,* and *iodide* respectively.—6. ZnO is reduced to zinc by heating with *carbon* or in *carbon monoxide.*—7. ZnO does not directly interact with *water*; ZnO_2H_2 is produced by ppg. a zinc salt solution by an alkali (*v.* ZINC HYDROXIDE, p. 888).—8. By heating ZnO with *oxides of aluminium, chromium,* and *iron* along with B_2O_3 in a pottery furnace until the B_2O_3 was volatilised, Ebelmen (*A. Ch.* [3] 33, 34) obtained the compounds $ZnO.Al_2O_3$, $ZnO.Cr_2O_3$, and $ZnO.Fe_2O_3$.

Zinc peroxide. In 1818 Thénard (*A. Ch.* [2] 9, 55) obtained what he called 'deutoxide de zinc' by the action of H_2O_2Aq on gelatinous ZnO_2H_2, and also by adding KOHAq to a solution of ZnO_2H_2 in HClAq to which H_2O_2 had been added. In 1884 Haas (*B.* 17, 2249) obtained a white, tasteless, neutral, gelatinous pp. by adding H_2O_2Aq to solutions of zinc salts and then adding NH_3Aq; after washing and drying at 100°, the solids had approximately the compositions Zn_5O_8 and Zn_3O_5. H. thinks it probable that the substances obtained by him were compounds of ZnO and ZnO_2; the formula $2ZnO.3ZnO_2$ agrees well with some of his analyses.

Zinc, oxybromides of. Oxybromides of zinc are formed by heating solutions of $ZnBr_2$ with ZnO, and by partially ppg. $ZnBr_2$Aq by NH_3Aq. Several compounds have been described by André (*Bl.* [2] 39, 398 [1884]):
(1) $ZnBr_2.4ZnO.xH_2O$, $x = 10$, 13, and 19;
(2) $ZnBr_2.5ZnO.6H_2O$; (3) $ZnBr_2.6ZnO.35H_2O$.

Zinc, oxychlorides of. These compounds are formed by adding to $ZnCl_2$Aq a quantity of NH_3Aq less than sufficient for complete ppn.; also by boiling $ZnCl_2$Aq with ZnO, or with certain other metallic oxides. Schindler (*Mag. Pharm.* 36, 45) obtained $ZnCl_2.3ZnO.4H_2O$ by boiling $ZnCl_2$Aq with ZnO, and the same compound by partially ppg. $ZnCl_2$Aq by NH_3Aq. By adding to $ZnCl_2$Aq so much NH_3Aq that the pp. which formed at first partly dissolved, and also by treating $ZnCl_2.4NH_3$ with water, Kane (*A. Ch.* 72, 296) obtained $ZnCl_2.6ZnO.10H_2O$. André (*C. R.* 106, 854) obtained $2ZnCl_2.3ZnO.11H_2O$ by boiling $ZnCl_2$Aq with HgO and letting the solution cool; using PbO he obtained another oxychloride, probably $ZnCl_2.3ZnO$, combined with $ZnCl_2.PbO$.

Zinc, oxyiodides of. According to Müller (*J. pr.* 26, 441 [1842]), ZnI_2Aq dissolves zinc when warmed therewith in the air; on cooling, an oxyiodide, $ZnI_2.3ZnO.2aq$, is ppd.

Zinc, oxysulphides of. The compound 4ZnS.ZnO occurs native as *voltzite*, as spherical globules in some specimens of *galena*. A compound having the same composition was found in a furnace flue at Freiberg by Karsten (*S.* 57, 186). By heating dry $ZnSO_4$ to redness in H, Arfvedson obtained a yellow-coloured oxysulphide ZnS.ZnO (*P.* 1, 59).

Zinc, perbromoplatinocyanide of, *v.* vol. ii. p. 345.

Zinc, phosphides of. Zinc and P combine when heated together, forming a greyish, lustrous, somewhat malleable compound. By heating finely powdered zinc in vapour of P, Schrötter obtained a compound, with S.G. 4·76, having the composition Zn_3P_2 (*W. A. B.* 1859. 301). Vigier obtained the same compound by heating zinc in H until distillation began, and then passing H laden with vapour of P over the zinc. The same compound was formed by Regnault (*A. Ch.* [4] 9, 162) by heating to whiteness a mixture of $MgHPO_4$, ZnS and C; along with the Zn_3P_2 were formed crystals of another phosphide, probably ZnP; and by treating Zn_3P_2 with dilute acid, an amorphous, yellow solid remained which detonated when mixed with $KClO_3$ and struck, and which was perhaps ZnP_6. The compound Zn_3P_2 was obtained by Hvoslef (*A.* 100, 99) by strongly heating a mixture of ZnO, P_2O_5, and C. By heating a mixture of $NaPO_3$ and zinc shavings in a retort, H. (*l.c.*) obtained a yellowish red, loose sublimate which contained Zn and P; and by heating the fused mass in the retort with HClAq, grey lustrous tablets of ZnP_2 remained. Lüpke (*C. C.* 1890 [ii.] 642) formed zinc phosphide (? Zn_3P_2) by adding amorphous P to molten zinc covered with $(NH_4)_2CO_3$; this phosphide was not decomposed by water, but was slowly decomposed by dilute HClAq, giving off PH_3.

For the compound ZnPH *v.* Zinc hydrophosphide, p. 888.

Zinc, platinocyanide of, *v.* vol. ii. p. 344.

Zinc, salts of. Many salts are obtained by replacing the H of acids by zinc. The greater number of the salts of zinc are normal salts; several basic carbonates, nitrates, and sulphates are known. The following are the chief salts of zinc derived from oxyacids:—*Arsenite* and *arsenate*, *borate*, *bromate*, *carbonates*, *chlorate* and *perchlorate*, *chromates*, *iodate* and *periodates*, *molybdates*, *nitrates* and *nitrites*, *phosphates* and *phosphites*, *selenate* and *selenite*, *silicate*, *sulphates* and *sulphite*, *thiosulphate*, *tungstates*, *vanadates* (*v.* Carbonates, Nitrates, Sulphates, &c.).

Zinc, selenide of, ZnSe. This compound is formed, in reddish-yellow, regular crystals, S.G. 5·40, by heating zinc to redness in a stream of H_2Se, and then subliming in a slow stream of H (Margottet, *C. R.* 84, 1293).

Zinc, selenocyanide of, *v.* vol. ii. p. 348.

Zinc, silicofluoride of, $ZnSiF_6.6H_2O$. Obtained in hexagonal plates, easily sol. in water, by evaporating to a small bulk a solution of ZnO in H_2SiF_6Aq (Berzelius). S.G. 2·104 (Topsöe, *C. C.* 4, 76).

Zinc, stannifluoride of, $ZnSnF_6.6H_2O$; *v.* this vol., p. 724.

Zinc, sulphocyanide of, *v.* vol. ii. p. 353.

Zinc, sulphide of, ZnS. This compound is not formed by heating together zinc and S, as the S volatilises before the temperature of combination is reached.

Occurrence.—As *zinc blende.*

Preparation.—1. By repeatedly subjecting a mixture of zinc and S, in the ratio Zn:S, to a great pressure; the product resembled zinc blende (Spring, *B.* 16, 1,000).—2. By rapidly heating a mixture of zinc filings and cinnabar in a retort; formation of ZnS occurs with detonation; Hg distils off.—3. By heating ZnO with S.—4. By heating ZnO, or ZnO_2H_2, in a stream of H_2S; in the case of ZnO_2H_2 formation of ZnS takes place very slowly (*v.* Wagner, *D. P. J.* 197, 334).—5. ZnS is also formed by heating dry $ZnSO_4$ with S and C.—6. ZnS is obtained by passing H_2S into a neutral or alkaline solution of a zinc salt, or into a solution in a weak acid, such as acetic acid, washing the pp., drying it at 100°, and heating in a stream of dry H_2S. The pp. dried at 100° is said to be $2ZnS.H_2O$ (Geiger a. Reimann, *Mag. Pharm.* 31, 178; *cf.* Souchay, *Fr.* 7, 78).

Properties and Reactions.—S.G. of ZnS = 3·93 (Karsten, *S.* 65, 394); S.G. of *blende* = 4·03 to 4·07 (*v.* Neumann, *P.* 23, 1). Thomsen (*Th.* 3, 276) gives H.F. of $ZnS.xH_2O$ as $[Zn,S,xH^2O] = 41,580$. ZnS prepared by ppn. is a yellowish solid; easily sol. in acid, forming salts of Zn and giving off H_2S. Zinc blende is a grey to black crystalline solid; slowly acted on by acids. By repeatedly washing ppd. ZnS, also by passing H_2S into water containing pure ZnO_2H_2 in suspension, Winssinger (*Bl.* [2] 49, 452 [1888]) obtained colloidal ZnS, sol. in water; the solution could be boiled until all excess of H_2S was expelled without ppn. of ZnS. ZnS prepared by adding excess of NH_3Aq to $ZnCl_2$Aq, ppg. all the zinc as ZnS by H_2S, washing and drying the pp., and then heating nearly to whiteness in a Hessian crucible inside a plumbago crucible, is very phosphorescent (*v.* Henry, *C. R.* 115, 503).

By heating ZnS with zinc in a vacuous tube, Morse a. White (*Am.* 11, 348) found that some of the ZnS was carried forward and deposited on the cooler part of the tube; they supposed that some of the ZnS was decomposed, and that Zn and S existed in the hottest part of the tube and combined in the cooler portions. By heating *blende* with I and a little water some $ZnSO_4$ is formed (Filhol a. Melhies, *A. Ch.* [4] 22, 58; Lasaulx, *J.* 1870, 1272).

According to Schiff (*A.* 115, 74), a *polysulphide of zinc*, probably ZnS_5, is formed by ppg. a neutral solution of a salt of zinc by K_2S_5Aq, and drying the pp. over H_2SO_4. Spring (*B.* 16, 1000) thought that a polysulphide of zinc was probably formed by strongly compressing a mixture of zinc with excess of S.

Zinc, telluride of, ZnTe. Obtained, in large ruby-red, regular crystals, by strongly heating zinc in a stream of H_2Te, and then subliming in a slow current of H (Margottet, *C. R.* 84, 1293).

Zinc, titanifluoride of, $ZnTiF_6$; *v.* this vol., p. 742.

M. M. P. M.

ZINC, ORGANIC COMPOUNDS OF.

Zinc methyl or **Zinc methide** ZnC_2H_6 *i.e.* $ZnMe_2$. Mol. w. 95. V.D. 3·29 (calc. 3·30). [−40°] (Haase, *B.* 26, 1053). (46°). S.G. $^{14.5}$ 1·386.

Formation.—1. By heating methyl iodide with zinc in sealed tubes at 150°. The compound IZnMe is formed as an intermediate product. The reaction takes place more easily when the MeI is mixed with two-thirds of its volume of ether and heated to 100°, but it is then difficult to separate the ether from the $ZnMe_2$ (Frankland, *A.* 85, 346; 111, 62; Wanklyn, *C. J.* 13, 124; Butlerow, *A.* 144, 2; Ladenburg, *A.* 173, 147).—2. By heating finely granulated zinc with $HgMe_2$ in a sealed tube for 24 hours at 120°, and distilling the product (Frankland a. Duppa, *C. J.* 17, 30).—3. IZnMe is formed in 24 hours if MeI is left in contact with a large amount of copper-zinc couple (Gladstone, *C. J.* 35, 109).

Preparation.—Zinc filings (9 pts.) are heated with reduced copper (1 pt.) till the copper-zinc couple is produced, and the product treated with MeI (Gladstone, *C. J.* 35, 569).

Properties.—Colourless mobile liquid, taking fire on exposure to air. Decomposed by water into CH_4 and $Zn(OH)_2$. By very careful oxidation it appears to yield $Zn(OMe)_2$ and crystalline $ZnMe(OMe)$, which is split up by water into $Zn(OH)_2$, methyl alcohol, and CH_4.

Reactions.—1. *Acetyl chloride* (1 mol.) forms $CH_3.CCl(OZnMe).CH_3$, which is slowly converted, by further treatment with $ZnMe_2$, into $CH_3.CMe(OZnMe).CH_3 + ClZnMe$, crystallising in prisms, and converted by water into *tert-butyl* alcohol, CH_4, zinc chloride, and $Zn(OH)_2$. The compound $CH_3.CCl(OZnMe).CH_3$ yields acetone on addition of water (Butlerow, *Z.* 1864, 365, 702; Pawlow, *N. Petersb. Acad. Bull.* 22, 497; Bogomoletz, *A.* 209, 88).—2. *Bromo-acetyl bromide*, followed by water, yields methyl-iso-propyl-carbinol (Winogradoff, *A.* 191, 127).—3. In ethereal solution *secondary hexyl iodide* has no action at 100°; but at 125° the products appear to be CH_4, ethyl iodide, and hexylene (Purdie, *C. J.* 39, 464).—4. *Chloral* followed by water forms $CCl_3.CHMe.OH$, while butyric chloral yields $C_3H_4Cl_3.CHMe.OH$.—5. *Nitric oxide* passed into $ZnMe_2$ forms $CH_3N_2O_2(ZnMe)$, which is decomposed by water, yielding crystalline $(CH_3N_2O_2)_2Zn$ aq, from which the Na salt $CH_3N_2O_2Na$ aq of 'di-nitro-methylic' acid may be obtained (Frankland, *A.* 99, 369).

Zinc ethyl or **Zinc ethide** $ZnEt_2$. Mol. w. 123. [−28°] (Haase, *B.* 26, 1053). (118°). S.G. ^{18} 1·182. H.F. −31,800 (Guntz, *C. R.* 105, 673). V.D. 4·26 (obs. and calc.).

Formation.—1. By heating zinc or zinc-sodium alloy with EtI or a mixture of EtI and ether (Frankland, *C. J.* 2, 297; 3, 44; *Tr.* 142, 431; 145, 259; *A.* 95, 28; Wanklyn, *C. J.* 13, 121; Pebal, *A.* 118, 22; 121, 105; Rieth a. Beilstein, *A.* 123, 245; 126, 248; Chapman, *Laboratory*, 1, 195; Alexejeff a. Beilstein, *C. R.* 63, 171; Rathke, *A.* 152, 220; Wichelhaus, *J.* 1868, 425).—2. By heating granulated zinc with $HgEt_2$ in sealed tubes for 36 hours at 100° (Frankland a. Duppa, *C. J.* 17, 3).—3. From zinc filings and EtBr (Wichelhaus, *A.* 152, 321).

Preparation.—Clean zinc filings (180 g.) are mixed with copper (20 g.) reduced from the oxide at a dull-red heat by coal gas; the mixture is rapidly heated over a very large Bunsen flame, and is well shaken meanwhile. As soon as the filings begin to cake together and the copper is no longer visible, the copper-zinc couple has been made. The flask is now connected with an inverted condenser, inclined slightly upwards, and when it is cold ethyl iodide (175 g.) is added. Dry CO_2 is passed through the apparatus, and the flask heated by a water-bath; in half an hour the EtI ceases to run back from the condenser, for it has been converted into IZnEt. The apparatus is now tilted so that the condenser is inclined downwards, and heated in a bath of paraffin. The reaction $2IZnEt = ZnI_2 + ZnEt_2$ now takes place, and $ZnEt_2$ (60 g.) is collected in a receiver kept full of CO_2 (Gladstone a. Tribe, *C. J.* 26, 445; 35, 569).

Properties.—Colourless, mobile liquid, fuming in the air, and quickly taking fire, burning with a luminous green-edged flame, and giving off clouds of ZnO. Immediately decomposed by water into $Zn(OH)_2$ and ethane. In like manner it attacks organic compounds containing hydroxyl or amidogen, with elimination of ethane. It causes india-rubber to swell remarkably.

Reactions.—1. Gradually treated with dry *oxygen* it appears to produce $ZnEt(OEt)$ and $Zn(OEt)_2$ successively (Frankland). According to Demuth a. Meyer (*B.* 23, 894), the passage of oxygen through a solution of $ZnEt_2$ in ligroin

(7 vols.) yields EtZn.O.O.Et, which is decomposed by heat, sometimes with explosive violence. The compound EtZn.O.OEt sets free I from a solution of KI and yields alcohol when distilled with dilute H_2SO_4.—2. *Sulphur* forms zinc mercaptide $Zn(SEt)_2$. Se appears to act in like manner (Chabrié, *Bl.* [3] 2, 788).—3. *Iodine* forms IZnEt and ZnI_2 successively, together with EtI. Bromine acts in like manner. Zinc ethyl takes fire in chlorine.—4. Dry *ammonia* forms $Zn(NH_2)_2$ and ethane (Frankland, *Pr.* 8, 502).—5. *Nitric oxide* is absorbed by an ethereal solution of $ZnEt_2$ forming crystalline $ZnEt_2(NO)_2$ which melts below 100° and is split up by water into ethane and $C_2H_5.N_2O_2.ZnOH$. Carbon dioxide passed into an aqueous solution of this salt ppts. zinc carbonate, while zinc 'dinitroethylate' $(C_2H_5N_2O_2)_2Zn$ remains in solution (Frankland, *Tr.* 1857, 59; *A.* 99, 342; *C. J.* 37, 570). The salt $(C_2H_5N_2O_2)_2Zn$ aq crystallises in prisms, yields NH_3 and NH_2Et on treatment with sodium-amalgam (Zuckschwerdt, *A.* 174, 302), and HNO_3 and NH_2Et on treatment with alcoholic potash (Zorn, *B.* 15, 1008). The dinitroethylates NaA′, BaA'_2, $CaA'_2$3aq, MgA'_2, $CuA'_2\frac{1}{2}$aq, AgA′, and $Ag_2A'(NO_3)$ were prepared by Frankland.—6. SO_2 forms zinc ethane sulphinate (Hobson, *C. J.* 10, 455).—7. PCl_3 yields PEt_3 (Hofmann a. Cahours, *Tr.* 1857, 578).—8. $SiCl_4$ gives $SiEt_4$.—9. Heated with EtI at 170° it forms *n*-butane and ZnI_2. Ethane and ethylene are also formed (Brodie, *C. J.* 3, 405). $ZnEt_2$ does not act on amyl iodide.—10. Displaces halogens in organic compounds by ethyl.—11. Adds itself to a carbonyl group. Thus with *di-ethyl-ketone* it forms $Et_2C(OZnEt).Et$, which is converted by water into tri-ethyl-carbinol. *Di-propyl ketone* forms, in like manner, ethyl-di-propyl-carbinol. Ketones containing the group $CO.CH_3$ act differently, forming condensation-products; thus acetone yields mesityl oxide and phorone (A. Saytzeff, *J. pr.* [2] 31, 319). Zinc ethyl has no action on paraldehyde (Wedensky, *J. pr.* [2] 39, 568). With acetic aldehyde it forms $CH_3.CHEt.OZnEt$, which is converted by water into *sec*-butyl alcohol.—12. In some cases it can add ZnEt and H to a carbonyl group, C_2H_4 being evolved. Thus $ZnEt_2$ converts *chloral*, dissolved in pure ether, into crystalline $CCl_3.CH_2.OZnEt$, which is converted by water into tri-chloro-ethyl alcohol (Delacre, *Bl.* [2] 48, 784). Further action of zinc ethide on chloral yields $(CCl_3.CH_2O)_2Zn$, a white powder. In like manner butyric chloral is converted into $C_3H_4Cl_3.CH_2.OH$. In this splitting off of an olefine, $ZnEt_2$ differs from $ZnMe_2$, but resembles zinc propyl and zinc isobutyl (Garzarolli, *A.* 223, 162).—13. Can displace oxygen by two ethyl radicles; thus it converts *oxalic ether* into $CO_2Et.CEt_2.CO_2Et$ (Frankland a. Duppa, *A.* 142, 1; *Pr.* 12, 396).—14. Can displace ethoxyl by ethyl. Thus it converts *formic ether* into HCEt(OZnEt).OEt and then into HCEt(OZnEt).Et, which is turned by water into di-ethyl-carbinol (Wagner a. Saytzeff, *A.* 175, 351).—15. Can displace chlorine by hydrogen. Thus with *chloro-benzoic acid* the first product is probably $C_6H_4(ZnEt).CO_2Et$, which is converted by water into benzoic ether, C_2H_6, and ZnO.—16. With *benzonitrile* at 150°, and subsequent treatment with alcohol, cyaphenine is formed (Frankland a. Evans, *C. J.* 37, 568). It polymerises phenyl-acetonitrile in the same way, forming cyanbenzine.—17. *Cyanogen* forms $ZnCy_2$ and EtCN (Frankland a. Graham, *C. J.* 37, 740).—18. *Azobenzene* is reduced by $ZnEt_2$, followed by water, to aniline (Frankland a. Louis, *C. J.* 37, 563).—19. Acts on primary and secondary amines, giving off ethane, but has no action on tertiary amines (Frankland, *Pr.* 8, 502; Gal, *J. Ph.* [5] 7, 484). $ZnEt_2$ has no action on nicotine or quinoline, but forms with many alkaloids containing O compounds from which the alkaloids are regenerated by water.—20. *Acetamide* gives $(AcNH)_2Zn$, while oxamide gives $C_2O_2(NH)_2Zn$.—21. Acts on $HgCl_2$, forming ClHgEt and $HgEt_2$ (Buckton, *A.* 109, 218). Hg_2Cl_2 yields $HgEt_2$, mercury, and $ZnCl_2$.—22. AgCl forms $ZnCl_2$, silver, and butane.—23. CCl_4 forms EtCl, ethylene, and propylene (Rieth a. Beilstein, *A.* 124, 242).—24. *Chloroform* yields amylene (R. a. B.), while bromoform gives propylene and EtBr (Alexejeff a. Beilstein, *C. R.* 58, 172). $CHCl_2I$ produces ethylene, butane, and hydrogen (Borodine, *A.* 126, 239).

Zinc bromo-ethide ZnBrEt. [62°]. Formed by the action of the copper-zinc couple on EtBr at 100° (Gladstone a. Tribe, *C. J.* 27, 410). Pearly scales, decomposed by heat partly into $ZnBr_2$ and $ZnEt_2$ and partly into Zn, $ZnBr_2$, C_2H_4, and C_2H_6.

Zinc iodo-ethide ZnIEt. Formed in like manner. Crystalline. Split up by heat into ZnI_2 and $ZnEt_2$.

Zinc propyl $ZnPr_2$. (148°) (S.); (146°) (Gladstone a. Tribe, *B.* 6, 1136); (150°) (Pape, *B.* 14, 1873). Formed by heating propyl iodide with zinc and a small quantity of an alloy of zinc and sodium (Stcherbakoff, *Bl.* [2] 37, 345). Heavy liquid, with disagreeable odour. Reacts with aldehydes, forming propylene and such compounds as $RCH_2.OZnPr$, which yield secondary alcohols on addition of water.

Zinc isopropyl $ZnPr_2$. (136°) with decomposition; (96° at 40 mm.). Got by heating PrI (170 g.) with ether (100 g.), zinc (100 g.), and zinc-sodium (3 g.) at 100° (Ragozin, *J. R.* 24, 549). Fuming liquid. Yields crystalline $Zn(OPr)_2$ on exposure to air. Split up at 132° into Zn and hydrocarbons (Gladstone a. Tribe, *C. J.* 39, 6).

Zinc isobutyl $Zn(C_4H_9)_2$. (166°) at 734 mm. (Garzarolli-Thurnlackh a. Popper, *A.* 223, 167). Formed from zinc and $Pr.CH_2I$. Got also from Zn and $Hg(C_4H_9)_2$ (Cahours, *Bl.* [2] 21, 357).

Zinc isoamyl $Zn(C_5H_{11})_2$. (220°). S.G. ^{0} 1·022. V.D. 6·95 (calc. 6·87). Prepared by heating zinc with $Hg(C_5H_{11})_2$ (Frankland, *A.* 85, 360; 130, 122). Liquid, fuming in the air but not taking fire. Takes fire in oxygen. When added to cooled aldehyde it yields, after addition of ice-cold water, methyl-isoamyl-carbinol, isopropyl-ethylene, and ethyl and isoamyl alcohols (Sokoloff, *C. C.* 1887, 988).

ZINCATES. Compounds derived from ZnO_2H_2 by replacing H by positive metals; *v.* ZINC HYDROXIDES, p. 888.

ZIRCONATES *v.* under ZIRCONIUM HYDROXIDE, p. 896.

ZIRCONIA; *oxide of zirconium* (*q. v.*, p. 896).

ZIRCONIUM. Zr. At. w. c. 90 (*v.* p. 894). Mol. w. not known. Melts above m.p. of Si (*i.e.* above c. 1300°) (Troost, *J.* 1865. 188). S.G. 4·15 (Troost, *l.c.*); 4·25 (Moissan, *C. R.* 116, 1222). S.H. (0°–100°) ·066 (Mixter a. Dana, A. 169, 388 [1873]).

Historical.—Klaproth in 1789 (*Beiträge*, 1, 203, 227) announced the discovery of a new earth, in combination with silica, in the rare mineral *zircon*. The same earth has been found in a few other rare minerals, such as *eudialyte*, *polymignite*, *fergusonite*, &c. Bright-coloured varieties of zircon are generally called *hyacinth*, the greyish or brown kinds are called *zirconite*, and a variety which is nearly colourless is known as *jargon*.

In 1845 Svanberg (*A.* 56, 223) stated that zirconia was a mixture of at least three oxides, but Berlin (*J. pr.* 58, 147), Marignac (*A. Ch.* [3] 60, 257), and Hermann (*J. pr.* 31, 75; 97, 331) failed to obtain any evidence of the composite character of zirconia. At a later time, Sorby (*B.* 2, 126, 193 [1869]), and also Forbes (*B.* 2, 337, 383), thought they had obtained spectroscopic indications of the presence of another earth in *zircon*; but it was shown that the abnormalities observed were due to traces of compounds of uranium (Sorby, *C. N.* 21, 73; Knop, *A.* 159, 44; *cf.* Hannay, *C. J.* 26, 703).

Occurrence.—Never uncombined. The principal naturally occurring compound of Zr is *zirconite*, which is more or less pure $ZrSiO_4$. This mineral is found in small quantities in the sand and alluvial deposits of certain rivers in Ceylon, and in the older rocks in many parts of the world; it has been found in the granites of Sweden, Switzerland, Tyrol, and North America (*v. J. M.* 1877. 97).

Formation.—1. By heating K_2ZrF_6 with K (Berzelius, *P.* 4, 117 [1825]).—2. By passing vapour of ZrF_4 over Na in a red-hot tube (Troost, *C. R.* 61, 109 [1865]).—3. By heating ZrO_2 with Mg (Phipson, *J. pr.* 96, 353 [1865]).—4. By melting ZrO_2 in a carbon crucible in an electric furnace; or by mixing ZrO_2 with carbon, melting in an electric furnace, then mixing the Zr carbides thus formed (*v. Carbides*, p. 894) with excess of ZrO_2 and again melting (Moissan, *C. R.* 116, 1222 [1893]).

Preparation.—1. Finely powdered *zirconite* ($ZrO_2.SiO_2$) is thoroughly mixed with an excess of finely powdered carbon, the mixture is compressed into small cylinders which are placed in a closed carbon crucible and heated in an electric furnace (with a current of 30 to 35 ampères and 70 volts), while a stream of CO_2 is sent through the crucible; the greater part of the SiO_2 is thus volatilised (Troost, *C. R.* 116, 1428). The carbides of Zr in the crucible are now mixed with excess of ZrO_2 and melted in the electric furnace (Moissan, *C. R.* 116, 1222).—2. Finely powdered and sifted *zirconite* is mixed with 2 to 3 times its weight of KHF_2, the mixture is heated to bright redness for c. 15 mins., and, after cooling, is boiled with water containing a little dilute HFAq; K_2SiF_6 is removed by filtration, the filtrate deposits K_2ZrF_6 on cooling. The K_2ZrF_6 is re-crystallised from water, then dried, mixed with K, and heated in a vessel of glass or iron; the product is washed with water, digested for a long time with conc. HClAq at 40°, then washed with water containing NH_4Cl, and finally with alcohol (Berzelius, *l.c.*; Troost, *A.* 136, 353). This method yields *amorphous zirconium*. According to Bailey (*Pr.* 46, 74 [1889]), the only method that gives nearly pure amorphous Zr is to heat ZrO_2 with Mg foil (not powder) and treat with HClAq.—3. *One part dry K_2ZrF_6 is mixed with 1½ pts. Al and the mixture is heated to the* melting-point of iron in a crucible made of gas coke; the product is digested with conc. HClAq diluted with twice its volume of water, when the crystalline leaflets of Zr, that have formed on the surface of the Al, separate from the mass of Al before the latter is wholly dissolved. When the whole of the Al has dissolved an alloy of Zr and Al remains, besides the crystalline leaflets of Zr; if the temperature of reduction is not sufficiently high, the main product is the Zr-Al alloy (Troost, *l.c.*; *cf.* Franz, *B.* 3, 58). This method yields *crystalline zirconium*.

Various methods have been used for decomposing *zirconite* and obtaining compounds of Zr. Franz (*B.* 3, 58) fuses the powdered mineral with $KHSO_4$, treats the fused material with boiling water containing a little H_2SO_4, washes the insoluble $3ZrO_2.SO_3$ thus formed, and adds it, in small portions at a time, to molten NaOH; he then lixiviates with cold water, dissolves the ZrO_2 that remains in hot conc. H_2SO_4, dilutes, ppts. by NH_3Aq, washes, dries, and decomposes the $ZrO_2.xH_2O$ by heat. The method of fusing with KHF_2 used by Marignac (*v. supra*, No. 2) yields pure K_2ZrF_6 very readily; $Zr(SO_4)_2$ may be obtained by heating the K_2ZrF_6 with conc. H_2SO_4 (*v.* Hiortdahl, *A.* 137, 34; *cf. J. pr.* 83, 201). For other methods *v.* Hermann (*J. pr.* 97, 330); Scheerer (*P.* 59, 48); Stromeyer (*A.* 113, 727); Chancel (*J. pr.* 74, 471); Berlin (*J. pr.* 58, 145); Henneberg (*J. pr.* 38, 508); Bailey (*Pr.* 46, 74 [1889]).

Properties.—Zirconium has been isolated as black amorphous powder, and also as a greyish crystalline solid.

Amorphous zirconium (*v. Preparation*, No. 2) is a black powder, which is extremely porous and resembles powdered charcoal; when pressed with a burnisher it agglomerates to graphite-like laminæ. After being heated strongly, and then cooled, *in vacuo*, it is said to glow and burn when exposed to air. The porous amorphous metal is said not to conduct electricity. Amorphous Zr is stated to be insoluble in ordinary acids, including *aqua regia*; but, according to Bailey (*Pr.* 46, 74 [1889]), it dissolves in cold conc. H_2SO_4; HFAq dissolves it readily, H being given off. It is oxidised by heating in the air, when it burns to ZrO_2 with a brilliant white light; oxidation is also effected by fusion with caustic or carbonated alkalis, or with KNO_3 or $KClO_3$.

Crystalline zirconium (*v. Preparation*, No. 3) is a very lustrous, greyish, brittle, solid, which resembles Sb in appearance; very hard, easily scratching glass and ruby (Moissan, *C. R.* 116, 1222). S.G. 4·15 (Troost, *J.* 1865. 183); 4·25 (Moissan, *l.c.*). S.H. (0° to 100°) ·066 (Mixter a. Dana, *A.* 169, 388 [1873]). Crystalline Zr burns in the O-H flame; it is not oxidised in O until heated to whiteness; it dissolves slowly in hot conc. HClAq, and is very slightly acted on by HNO_3Aq or H_2SO_4, even when warm; cold HFAq dissolves it readily. Molten $KClO_3$, or KNO_3, is said to be without action; molten KOH dissolves the metal as long as any moisture is present.

According to Troost (*J.* 1865. 188), Zr melts above the m.p. of Si (*i.e.* above c. 1800°). The emission-spectrum of Zr has been mapped by Thalén; the chief lines are 6127 in the red, and in the blue, 4815, 4771, 4738, 4709, and 4686.

The at. w. of Zr was determined, (1) by Berzelius (*P.* 4, 126; 8, 186 [1825]), by finding the ratio of ZrO_2 to SO_3 in the sulphate; (2) by Hermann (*J. pr.* 31, 77 [1844]) by analysing $ZrCl_4$: (3) by Marignac (*A. Ch.* [3] 60, 270 [1860]), by analysing K_2ZrF_6; (4) by Bailey (*Pr.* 46, 74 [1889]), by decomposing $Zr(SO_4)_2$ by heat and weighing the ZrO_2 produced; (5) by Mixter a. Dana (*A.* 169, 388 [1873]), by determining the S.H. of Zr; (6) by Deville a. Troost (*P.* 108, 636; 641 [1859]), by determining the V.D. of $ZrCl_4$. The results of Berzelius gave the at. w. of Zr as 89·2; those of Hermann, 88·5 to 90·7; those of Marignac, 90·3 to 90·6; and the results obtained by Bailey gave 90·4 as the at. w. of the metal.

Zirconium is the third member of the even-series family of Group IV. in the periodic classification of the elements. This group contains the following elements:—

Even Series	2	4	6	8	10	12
	C	Ti	Zr	Ce	—	Th
Odd Series	3	5	7	9	11	
	Si	Ge	Sn	—	Pb	

As is to be expected from its position in the classificatory system, Zr is a metal with some non-metallic properties; the oxide ZrO_2 forms corresponding salts, many of which are basic salts; the haloid compounds, ZrX_4, are probably all volatilisable without decomposition (the V.D. of $ZrCl_4$ only has been determined), but aqueous solutions yield oxyhalides on evaporation; hydrated ZrO_2 reacts as a weak acid towards strong bases, forming zirconates; salts are known derived from the acid H_2ZrF_6; there is an oxide higher than ZrO_2, probably ZrO_3. For a more detailed comparison of Zr with the other even-series elements of Group IV. *v.* TITANIUM GROUP OF ELEMENTS (this vol. p. 749), and *cf.* TIN GROUP OF ELEMENTS (this vol. p. 735). The atom of Zr is tetravalent in the gaseous molecule $ZrCl_4$.

Reactions and Combinations.—1. Heated in *air*, or *oxygen*, Zr burns to ZrO_2, giving out dazzlingly white light; amorphous Zr burns easily, crystalline only at a white heat, and then merely superficially.—2. Both amorphous and crystalline Zr dissolve readily in *hydrofluoric acid*, giving off H and forming ZrF_4.—3. According to Bailey (*Pr.* 46, 74), amorphous Zr dissolves in cold conc. *sulphuric acid.* Both forms dissolve in *aqua regia.*—4. Conc. *hydrochloric acid* reacts with Zr, when warm, forming $ZrCl_4$ solution. Crystalline Zr is said to interact with *gaseous hydrogen chloride*, at dull redness, forming $ZrCl_4$.—5. Amorphous Zr is oxidised by *molten potash* or *soda*, also by *molten nitre* or *potassium chlorate*; the crystalline form of Zr is said not to be acted on by molten KNO_3 or $KClO_3$, and by molten caustic alkalis only as long as there are traces of moisture present.—6. Zr combines directly with the *halogens*, to form ZrX_4, and probably with *sulphur* (*v. Sulphide*, p. 897).

Detection and Estimation.—Addition of hot conc. K_2SO_4Aq to solutions of salts of Zr ppts. white basic sulphate of Zr, which is insoluble in water and nearly insoluble in much HClAq. Turmeric paper becomes reddish-brown when immersed in a solution of a salt of Zr in HClAq; the reaction is completely masked by the presence of boric acid (*v.* Brush, *J. pr.* 62, 7). Bailey (*C. J.* 49, 481 [1886]) found that addition of H_2O_2Aq to a slightly acid solution containing salts of Zr, along with salts of Fe, Nb, and Ti, ppd. the whole of the Zr as ZrO_3 (or Zr_2O_5), but none of the other metals. Troost makes use of the comparatively small volatility of ZrO_2 at a very high temperature, to separate this oxide from SiO_2 (*v. C. R.* 116, 1428).

Zr is generally estimated as ZrO_2; salts of volatilisable acids are decomposed by heat; or solutions may be ppd. by NH_3Aq and the pp. washed, dried, and strongly heated.

Zirconium, alloys of. An alloy of Zr with *aluminium* is obtained in the preparation of Zr by reducing K_2ZrF_6 by Al (*v. Preparation of Zirconium*, No. 3). Mellis (*Z.* [2] 6, 296) obtained crystals having the composition $ZrAl_3$ (or perhaps Zr_2Al_6Si) by heating to whiteness a mixture of 1 pt. powdered *zirconite* with 5 pts. *cryolite* powder, 10 pts. mixed KCl and NaCl, and 1 pt. Al, treating with dilute HClAq, and separating the larger crystals of the alloy from the finer crystals of Si.

Zirconium, bromide of, $ZrBr_4$. Formula probably molecular, from analogy of $ZrCl_4$. Obtained by mixing finely powdered ZrO_2 with sugar charcoal, making into balls with starch paste, drying, and heating to bright redness in a current of *dry* CO_2 and *dry* Br (Mellis, *Z.* [2] 6, 296). $ZrBr_4$ is a white, microscopically crystalline, hygroscopic powder; it is easily volatilised; heated in H it is not reduced to a lower bromide. Contact with moist air or water produces the oxybromide $ZrOBr_2$; evaporation of an aqueous solution gives the heptahydrate of this compound $ZnOBr_2.7H_2O$ in large needle-shaped, transparent crystals (M., *l.c.*).

Zirconium, carbides of. By heating an intimate mixture of ZrO_2 and C in the electric arc, in an atmosphere of CO_2, Troost (*C. R.* 116, 1227 [1893]) obtained a very hard, steel-grey solid, approximating closely to the composition ZrC_2. By using less C, other carbides seem to be produced (*cf.* Moissan, *C. R.* 116, 1222), but analyses of other compounds are not given. ZrC_2 dissolves easily in dilute HFAq, but is not acted on by other acids. Moissan (*l.c.*) says that carbides of Zr containing more than 5 p.c. C (ZrC_2 contains c. 21 p.c. C) take fire fairly easily when exposed to the air; Troost says that carbides with a small proportion of C are only superficially oxidised by heating to redness, but that those with much C burn brilliantly at that temperature.

Zirconium, chloride of, $ZrCl_4$. Mol. w. c. 231·5. V.D. 117 at 440° (Deville a. Troost, *P.* 108, 636).

Formation.—1. By heating Zr in Cl.—2. By heating an intimate mixture of ZrO_2 and C in Cl.—3. By passing vapour of $SiCl_4$ over heated ZrO_2 (Troost a. Hautefeuille, *C. R.* 75, 1819).

Preparation.—A mixture of ZrO_2 with c. its own weight of lampblack is made into a paste with oil; little balls, c. the size of hazel-nuts are formed of this, and these are covered with powdered charcoal, and heated to full redness in a closed crucible until the oil is completely charred; the pellets are then heated to bright redness in a tube of hard glass, while a current of dry Cl is passed through the tube; the $ZrCl_4$ which forms on the cooler parts of the tube is sublimed, in a stream of dry Cl, into a tube drawn out into bulbs, which are sealed off when the operation is finished (*v.* Bailey, *Pr.* 46, 74).

Properties, Reactions, and Combinations.—A white solid; volatilises unchanged at c. 400°. Dissolves in *water*, with production of heat; the solution on evaporation gives *oxychlorides* (*q.v.*). Does not interact with *zinc ethide* at 180° (Hinsberg, *A.* 239, 253). Combines with *ammonia* to form $ZrCl_4.4NH_3$; with *sodium chloride* to form $ZrCl_4.2NaCl$ (Paykull, *B.* 6, 1467).

Zirconium, ferrocyanide of. According to Hornberger (*A.* 181, 232), the pp. formed by adding K_4FeCy_6Aq to a solution of a salt of Zr, when washed and dried, has the composition $Zr_3(FeCy_6)_2$(?); it is a blue powder with a greenish tinge, insoluble in water, decomposed by acids, giving off HCN.

Zirconium, fluoride of, ZrF_4. Formula probably molecular, from analogy of $ZrCl_4$.

Formation.—1. The *hydrated* compound $ZrF_4.3aq$ is formed by slowly evaporating a solution of ZrO_3H_2, or ZrF_4, in HFAq.—2. By heating ZrO_2 with twice its weight of $(NH_4)HF_2$ to dull redness, till all the ammonium salt is volatilised (Marignac, *A. Ch.* [3] 60, 263).

Preparation.—Deville (*A. Ch.* [3] 49, 84) obtained ZrF_4 by heating to whiteness a mixture of finely powdered *zirconite* and *fluorspar* in a stream of HCl (? $ZrSiO_4 + 2CaF_2 + 2HCl = ZrF_4 + CaCl_2 + CaSiO_3 + H_2O$).

Properties and Reactions.—Prepared as described, ZrF_4 is a colourless, transparent, crystalline (probably hexagonal) solid; volatilisable at white heat; insoluble in water and acids. ZrF_4 prepared by heating ZrO_2 with $(NH_4)HF_2$ is said to be soluble in water and in dilute HFAq. The crystals of $ZrF_4.3aq$ are partially decomposed on drying. Heated to full redness in air, ZrF_4 gives ZrO_2 and HF.

Combinations.—1. With *water* (*v. Formation*, No. 1) to form $ZrF_4.3aq$.—2. With various *metallic fluorides* to form compounds of the form $ZrF_4.xMF.yH_2O$. These salts are often called *zircono-fluorides*, or *fluo-zirconates*; they are better named *zirconi-fluorides*. The zirconi-fluorides have been examined chiefly by Marignac (*A. Ch.* [3] 60, 257); they are obtained either by gradual evaporation of solutions containing the constituent fluorides, or by adding hydroxides or carbonates of the various metals to solutions of ZrF_4 in HFAq, and evaporating.

Ammonium zirconi-fluorides. Two salts are described: (1) $2NH_4F.ZrF_4 = (NH_4)_2ZrF_6$, rhombic crystals, isomorphous with K_2ZrF_6; (2) $3NH_4F.ZrF_4$, small octahedra, showing simple refraction (Baker, *C. J.* 35, 762).

Cadmium zirconi-fluorides. Two salts seem to exist: (1) $2CdF_2.ZrF_4.6aq$, monoclinic crystals, isomorphous with the Mn salts; (2) $CdF_2.2ZrF_4.6aq$, laminar, fan-shaped groups of crystals.

Manganese zirconi-fluorides. (1) $MnF_2.ZrF_4.5aq$; and (2) $2MnF_2.ZrF_4.6aq$.

Nickel zirconi-fluorides. (1) $NiF_2.ZrF_4.6aq$, hexagonal prisms; S.G. 2·227 (Topsöe, *C. C.* 4, 76); and (2) $2NiF_2.ZrF_4.12aq$, monoclinic crystals. The first salt forms a *double salt* with K_2ZrF_6, viz. $NiZrF_6.K_2ZrF_6.8aq$.

Potassium zirconi-fluorides. (1) K_2ZrF_6; obtained by strongly heating *zirconite* with two or three times its weight of KHF_2, boiling with very dilute HFAq, filtering from K_2SiF_6, and allowing the filtrate to cool. Crystallises in rhombic crystals, terminated by six-sided pyramids; solubility = ·78 at 2°, 1·4 at 15°, 2·7 at 19°, and 25 at 100°. S.G. 3·582 (Topsöe, *l.c.*); (2) $KF.ZrF_4.aq$ ($= KZrF_5.aq$); obtained, in monoclinic crystals, by dissolving the preceding salt in water containing a large excess of ZrF_4. (3) $3KF.ZrF_4$ ($= K_3ZrF_7$); obtained by crystallising K_2ZrF_6 from a solution containing excess of KF; small, brilliant, regular octahedra, with simple refraction (*v.* Baker, *C. J.* 35, 762). Soluble in water; the hot conc. solution deposits K_2ZrF_6 on cooling.

Sodium zirconi-fluorides. The salt $5NaF.2ZrF_4$ is said to be always formed in whatever proportion the constituent fluorides are mixed. Small, monoclinic crystals; solubility at 18° = ·38, and at 100° = c. 1·6.

Zinc zirconi-fluorides. (1) $ZnZrF_6.6aq$, isomorphous with $ZnSiF_6.6aq$ and $ZnSnF_6.6aq$, crystallising in regular hexagonal prisms, easily soluble in water. S.G. 2·255 (Topsöe, *l.c.*). (2) $2ZnF_2.ZrF_4.12aq$; deposited from a solution containing excess of ZnF_2, in monoclinic crystals, isomorphous with $2NiF_2.ZrF_4.12aq$.

Zirconium, hydride of. By heating ZrO_2 and Mg powder, in the ratio ZrO_2:2Mg, in an atmosphere of H, Winkler (*B.* 24, 888; *cf. B.* 23, 2666) obtained a black powder which burnt in O, and contained c. ·73 p.c. H. On treating this with dilute HClAq, Mg and MgO dissolved, H being given off, and a black residue was left which W. regarded as ZrH_2. Supposing the reduction of the ZrO_2 had proceeded in accordance with the equation $ZrO_2 + 2Mg + 2H = 2MgO + 2ZrH_2$, the product would have contained 53·44 p.c. ZrH_2, and, therefore, would have given 1·15 p.c. H; as only ·73 p.c. H was found, W. concluded that c. $\frac{1}{3}$ of the ZrO_2 had been reduced.

Zirconium, hydroxide of, (?) ZrO_3H_2. Addition of NH_3Aq to a solution of a salt of Zr produces a white, bulky, gelatinous pp. of $ZrO_2.xH_2O$. According to Berzelius, the dry pp. has the composition $ZrO_2.H_2O = ZrO_3H_2$; Hermann (*J. pr.* 97, 318) gave the formula $ZrO_2.2H_2O = ZrO_4H_4$ to the pp. dried at 17·5°; Paykull (*B.* 12, 1719) said that after drying *in vacuo* the composition was $ZrO_2.3H_2O$. and after drying at 100° $ZrO_2.H_2O$. A detailed examination of the dehydration of the pp. formed by adding NH_3Aq to a cold solution of $Zr(SO_4)_2$ was made by Carnelley a. Walker (*C. J.* 53, 88, 82 [1888]). The loss of water by the air-dried pp. was fairly regular to c. 90°, when the pp. had approximately the composition $ZrO_2.2H_2O$; the loss was then less rapid, but very regular, up to c. 385°, whereat the composition was approximately $2ZrO_2.H_2O$; somewhere between 385° and 415° there was a sudden increase in the percentage loss of water for a rise of 10°, this increase being accompanied by a change of colour from grey to pure white; at 415° the composition was approximately $24ZrO_2.H_2O$; water was then given off very regularly, until at c. 550° dehydration was completed. C. a. W. conclude that probably no definite hydrate of ZrO_2, unchanged throughout a fair range of temperature, is formed by heating $ZrO_2.xH_2O$ ppd. from a salt of Zr; they think that the change of colour which accompanies the comparatively large percentage loss of water at c. 400° is an accompaniment of a condensation of molecules chiefly of the composition $n(2ZrO_2.H_2O)$ to molecules chiefly of the composition $n(24ZrO_2.H_2O)$. There is a distinct resemblance between the phenomena of the dehydration of $ZrO_2.xH_2O$ and those of the dehydration of $SiO_2.xH_2O$, $SnO_2.xH_2O$, and $TiO_2.xH_2O$.

Hydrated ZrO_2 ppd. cold, and washed with cold water, dissolves easily in the ordinary acids, including oxalic acid (Bailey, *C. J.* 49, 481), forming salts ZrX^I_4 and ZrX^{II}_2; when ppd. hot, or washed with hot water, the pp. is only slowly dissolved by the ordinary acids. According to Paykull (*B.* 12, 1719), moist $ZrO_2.xH_2O$ absorbs CO_2 from the air. Digestion with $Zr(SO_4)_2Aq$ produces basic sulphates $3ZrO_2.4SO_3.15aq$ and $6ZrO_2.7SO_3.19aq$ (*P.*, *l.c.*).

ZIRCONATES. $ZrO_2.xH_2O$ behaves as a weak acid towards the stronger bases. A few salts have been prepared which are most simply regarded as derived from $Zr(OH)_x$ by replacing H by alkali and alkaline earth metals; these zirconates are obtained by heating ZrO_2 with bases; they have been examined chiefly by Hiortdahl (*A.* 137, 34, 236 [1865]).

Sodium zirconates. (1) Na_2ZrO_3 ($=Na_2O.ZrO_2$); obtained by heating ZrO_2 with Na_2CO_3 in the ratio $ZrO_2:Na_2CO_3$; the crystalline mass thus formed is gradually decomposed by water with separation of amorphous ZrO_2. (2) Na_4ZrO_4 ($=2Na_2O.ZrO_2$); obtained by heating ZrO_2 with a considerable excess of Na_2CO_3 to whiteness for a considerable time; decomposed by water, with formation of (3)$Na_2O.8ZrO_2.12aq$, which forms hexagonal tablets.

Zirconates of calcium and *magnesium* were obtained by H (*l.c.*) by heating to redness mixtures of ZrO_2 with SiO_2 and $CaCl_2$ or $MgCl_2$. Ouvrard (*C. R.* 112, 1444 [1891]) describes *lithium zirconate*, Li_2ZrO_3, obtained by fusing ZrO_2 with LiCl, and cooling slowly; when Li_2CO_3 was used, and the fused mass was treated with boiling water containing a little acetic acid, pure ZrO_2 remained.

Zirconium, nitride of. In fusing amorphous Zr with Al, in a cracked lime crucible, Mallet (*Am. S.* [2] 28, 346 [1858]) obtained a dark-grey, porous solid, which gave yellowish lustrous microscopic cubes when treated with HClAq; the crystals were unchanged by *aqua regia* or alkali solutions; when fused with KOH they gave off NH_3. The yellow crystals were probably a nitride of Zr.

Zirconium, oxides of. Besides zirconia, ZrO_2, there exists a higher oxide, probably ZrO_3; and, possibly, also a lower oxide (?) ZrO.

ZIRCONIUM DIOXIDE ZrO_2. (*Zirconia. Zirconic anhydride.*) Mol. w. not known.

Preparation.—There are many methods for preparing ZrO_2 from *zirconite*. 1. The mineral is heated to redness and thrown into water, and the least-coloured pieces are finely powdered and levigated; the powder is very strongly heated with four times its weight of Na_2CO_3, in a Pt crucible, and the product is heated with excess of HClAq; the whole is evaporated to dryness; the residue is digested with water, filtered from SiO_2, and $ZrO_2.xH_2O$ is ppd. by NH_3Aq. The pp. is washed and dissolved in HClAq, and the solution is nearly saturated with Na_2CO_3, and boiled with $Na_2S_2O_3Aq$ as long as SO_2 is given off, whereby $ZrO_2.xH_2O$ is ppd. (Berzelius, *P.* 4, 124; 8, 186; Hermann, *J. pr.* 31, 77; Chancel, *A.* 108, 237; Stromeyer, *A.* 113, 127).—2. Very finely powdered *zirconite* is boiled with conc. HClAq, and the residue is washed with water and dried; 100 g. of the dried powder are added to 400 g. molten NaOH, with which 20 g. NaF have been mixed, and the whole is heated in a nickel crucible until the action ceases, when the molten mass is poured on to a sheet of nickel, and, after solidification, is plunged into water; the portion insoluble in water is dissolved in HClAq, the solution is evaporated to dryness, and treatment with HClAq and evaporation to dryness are repeated several times to remove SiO_2 and HF. The solution in HClAq is then ppd. by NH_3Aq; the $ZrO_2.xH_2O$ is thoroughly washed by decantation, dissolved in the smallest possible quantity of conc. HClAq, and the solution is evaporated to dryness; the residue is washed in a funnel with conc. HClAq mixed with 4 pts. of alcohol; the washed solid is then repeatedly crystallised from conc. HClAq. The white, lustrous crystals of $ZrOCl_2.xH_2O$ thus obtained are dissolved in water, and $ZrO_2.xH_2O$ is ppd. by NH_3Aq (Venable, *C. N.* 64, 315 [1891]; *cf.* Bailey, *Pr.* 46, 74 [1889]; *cf. Preparation* of ZIRCONIUM, p. 893). By heating ppd. $ZrO_2.xH_2O$ to c. 550°, ZrO_2 is obtained.

Crystalline zirconia is obtained from the amorphous form (1) by fusing with borax at a very high temperature, and washing with HClAq (Nordenskjöld, *P.* 114, 612; Knop, *A.* 157, 363); (2) by fusion with *microcosmic salt* (K., *l.c.*); (3) by heating to dull redness in dry HCl at a pressure of three atmospheres (Hautefeuille a. Perrey, *C. R.* 110, 1038); (4) by melting and volatilising in an electric furnace, using a current of 360 ampères and 70 volts (Moissan, *C. R.* 116, 1222 [1893]); (5) by heating, to dull redness, a salt of Zr with an acid that can be removed by heating, in a current of dry HCl (H. a. P., *l.c.*).

Properties.—Amorphous zirconia is a white, tasteless, inodorous powder; S.G. c. 5·5; insoluble in acids, except in conc. H_2SO_4 (*v. Reactions*, No. 7) or HFAq. Crystalline zirconia is a transparent, colourless solid; S.G. 5·1 (Moissan, *l.c.*), 5·42 (Knop, *l.c.*), 5·7 (Nordenskjöld, *l.c.*). The crystals are described by N. (*l.c.*) as quadratic prisms, isomorphous with SnO_2 (*tinstone*) and TiO_2 (*rutile*). The crystals are extremely hard; they scratch glass easily (Moissan, *l.c.*). It is generally said that when ZrO_2 is heated to incipient redness it glows brightly, and becomes denser; but the experiments of Carnelley a. Walker (*C. J.* 53, 82 [1888]) on the action of heat on $ZrO_2.xH_2O$

make it probable that the glowing is an accompaniment of the dehydration from approximately $2ZrO_2.H_2O$ to approximately $24ZrO_2.H_2O$. Zirconia reacts towards acids as a basic oxide, forming salts ZrX^{I}_4 and ZrX^{II}_2 (many of which are basic salts); it also decomposes alkali carbonates and some other alkali and alkaline earth salts, when fused therewith, forming zirconates $mZrO_2.nM_2O$ (*v. Zirconates*, p. 896).

Reactions.—1. When ZrO_2 is *heated* to a very high temperature it melts, boils, and volatilises, condensing in crystals; Moissan (*C. R.* 116, 1222 [1893]) effected the volatilisation in a crucible heated in the electric furnace, using a current of 300 ampères and 70 volts. 2. When very strongly *heated with excess of carbon*, carbides are formed (*v. Carbides*, p. 894). Heating in a carbon crucible in the electric furnace produces Zr (M., *l.c.*).—3. Heating with *magnesium* produces Zr, perhaps also an oxide lower than ZrO_2 (Winkler, *B.* 23, 2642; 24, 888; Phipson, *J. pr.* 96, 353; Bailey, *Pr.* 46, 74; *cf. Zirconium monoxide*). When *heated with magnesium in an atmosphere of hydrogen*, some ZrH_2 is perhaps produced (*v. Zirconium hydride*, p. 895).—4. $ZrCl_4$ is formed by heating ZrO_2 mixed with *carbon in a stream of chlorine*; using *bromine* produces $ZrBr_4$ (*v. Bromide* and *Chloride*, p. 894).—5. ZrF_4 is formed by heating ZrO_2 to dull redness with excess of *ammonium fluoride*.—6. K_2ZrF_6 is formed by slightly heating ZrO_2 with excess of *potassium hydrogen fluoride*, boiling with very dilute HFAq, and filtering.—7. $Zr(SO_4)_2$ is obtained by heating ZrO_2 with excess of a mixture of 2 pts. *conc. sulphuric acid* and 1 pt. water.

ZIRCONIUM PEROXIDE. By adding H_2O_2Aq and NH_3Aq to a solution of $Zr(SO_4)_2$, Clève (*Bl.* [2] 43, 53) obtained an oxide containing more O than ZrO_2; to this oxide he gave the formula ZrO_3. Bailey in 1886 (*C. J.* 49, 149, 481) examined the pp. obtained by adding H_2O_2Aq to solution of $Zr(SO_4)_2$; according to B., the moist pp. has the composition Zr_2O_5, and this composition is unchanged after keeping (moist) for some months. In Bailey's paper in 1889 (*Pr.* 46, 74) he gives the composition $ZrO_3.3H_2O$ to the oxide ppd. by H_2O_2Aq, either from an acid or an alkaline solution of $Zr(SO_4)_2$, after drying over P_2O_5; and the composition Zr_2O_5 after drying at 100°. The oxide $ZrO_3.xH_2O$ was obtained (*C. J.* 49, 485) by preparing a solution of $Zr(SO_4)_2$ by heating K_2ZrF_6 with H_2SO_4, and at once adding H_2O_2Aq. Zr peroxide is insol. in very dilute (1 p.c.) H_2SO_4Aq or $HC_2H_3O_2Aq$ (B., *l.c.*). Bailey (*l.c.*) employed the ppn. of $ZrO_2.xH_2O$ to separate Zr from Fe, Nb, and Ti.

ZIRCONIUM MONOXIDE (?)ZrO. By heating ZrO_2 and powdered Mg, in the ratio ZrO_2:Mg, in a stream of H, Winkler (*B.* 23, 2668 [1890]) obtained a black powder, which he allowed to cool in H, then kept for some time in CO_2, freed from Mg by treatment with dilute HClAq, washed with water containing HCl, then with alcohol, and finally with ether, and dried *in vacuo*. He thus obtained a deep-black powder, which was unacted on by HClAq, HNO_3Aq, or H_2SO_4Aq, even on warming, and which burnt to ZrO_2 when heated in air. W. supposed this black powder to be ZrO.

Zirconium, oxyacid of. Hydrated zirconia, $ZrO_2.xH_2O$, reacts as a weak acid towards strong bases (*v.* ZIRCONATES, p. 896).

Zirconium, oxybromide of, $ZrOBr_2.xH_2O$. $ZrBr_2$ dissolves in water; on evaporation, transparent needle-shaped crystals are formed, to which Mellis (*Z.* [2] 6, 296) gave the composition $ZrOBr_2.7H_2O$. By dissolving $ZrO_2.xH_2O$ in HBrAq and evaporating, Weibull (*B.* 20, 1394 [1887]) obtained lustrous needles of $ZrOBr_2.8H_2O$, isomorphous with $ZrOCl_2.8H_2O$.

Zirconium, oxychlorides of. Various oxychlorides have been described. (1) $ZrOCl_2.xH_2O$; prepared by dissolving $ZrO_2.xH_2O$ in HClAq and evaporating (for details as to the best conditions *v.* Weibull, *B.* 20, 1394). Hermann (*J. pr.* 81, 77) gave the formula as $ZrOCl_2.9H_2O$; Mellis (*Z.* [2] 6, 296) gave $2ZrOCl_2.9H_2O$; and Weibull (*l.c.*) $ZrOCl_2.8H_2O$ (*v.* also Paykull, *B.* 6, 1467; and Bailey, *Pr.* 46, 74). (2) Zr_2OCl_6; prepared by Troost a. Hautefeuille (*C. R.* 73, 563) by passing steam and vapour of $ZrCl_4$ through a red-hot tube. (3) $2Zr_2O_3Cl_2.15H_2O$; prepared by Endemann (*J. pr.* [2] 11, 219) by adding ether to a warm alcoholic solution of $ZrOCl_2.xH_2O$.

Zirconium, oxyiodides of. By adding the calculated weight of BaI_2, in solution, to $Zr(SO_4)_2$ dissolved in a slight excess of H_2SO_4Aq, filtering, evaporating over H_2SO_4, and removing free I from the residue by CS_2, Hinsberg (*A.* 239, 253 [1887]) obtained a white, amorphous powder, easily soluble in water, giving off I in moist air, to which he gave the formula $ZrIO_3H_3.xH_2O$ (x probably = 3).

Zirconium, oxysulphide of; *v.* ZIRCONIUM SULPHIDES (*infra*).

Zirconium, salts of. The salts formed by the replacement of H of acids by Zr belong to the forms ZrX_2^{II} and ZrX_4^{I}; many basic salts are known. The following are the chief salts of Zr derived from oxyacids: *Arsenates, borates, carbonates, nitrates, oxalates, phosphates, selenites, silicates, sulphates*, and *sulphites*.

Zirconium, silicofluoride of, (?)$ZrSiF_6$; probably obtained by Berzelius by evaporating a solution (? of $ZrO_2.xH_2O$ in H_2SiF_6Aq) (*v. Lehrbuch*, 3, 505 [5th ed.]).

Zirconium, sulphides of. According to Berzelius (*v. Lehrbuch*, 2, 189 [5th ed.]), a compound of Zr and S is formed by heating the elements together *in vacuo*, or with H. The compound, to which no formula is assigned, is described by B. as a dark-brown coloured powder; unacted on by H_2SO_4Aq, HNO_3Aq, or HClAq; slowly attacked by boiling *aqua regia*; dissolved easily by HFAq, giving off H_2S; insol. in KOHAq, and decomposed by fusion with KOH to K_2S and ZrO_2. By strongly heating ZrO_2 in vapour of CS_2, Fremy (*A. Ch.* [3] 38, 326 [1858]) obtained a graphite-like solid, which was rapidly acted on by HNO_3Aq, with separation of S; Fremy supposed that the substance might be an oxysulphide.

Zirconium, sulphocyanide of. By adding $Ba(SCN)_2$ to $Zr(SO_4)_2$ solution, Hornberger (*A.* 181, 232 [1876]) obtained a solution which, he said, contained $Zr(SCN)_4$; this solution quickly decomposed, depositing a yellow solid, while $Zr(SCN)_2$ remained in solution.

M. M. P. M.

ADDENDA

[DESCRIPTIVE INORGANIC CHEMISTRY ONLY.]

ALUMINIUM (vol. i. p. 141). *Preparation.*—By electrolysing a molten mixture of $AlF_3.3NaF$ with NaCl (Minet, *C. R.* 111, 603 [1890]). The best results are obtained by using the salts in the ratio $AlF_3.3NaF$:6NaCl; details of the quantities to be used, the strength of current, &c., are given by M.

Properties.—Minet (*C. R.* 111, 603 [1890]) gives m.p. of Al as 675°; and S.G. at 820° as 1·76. The S.H. of Al is given by Richards (*C. N.* 65, 97 [1892]) as ·221 at 20°, ·232 at 100°, and ·2845 at the m.p. = 625°; the S.H. of molten Al at 650° = ·308, according to Pionchon (*C. R.* 115, 162 [1892]). The molecule of Al in dilute solution in tin is perhaps diatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]).

Reactions.—Volatilises in electric furnace, with current of 250 ampères and 70 volts (Moissan, *C. R.* 116, 1429 [1893]). Not appreciably acted on by NO_2 at 500° (Sabatier a. Senderens, *C. R.* 115, 236 [1892]). An amalgam is formed by bringing Al into a solution of a mercuric salt (Klaudy, *C. C.* 1893 [1] 201; abstract in *C. J.* 64 [11] 376 [1893]). Heated with $NaPO_3$ in a current of H, from 28 to 31 p.c. of the P distils over; P is also obtained by heating Al with any phosphate of Ca or Mg (Rossel a. Frank, *B.* 27, 52 [1894]). According to Lunge (*C. N.* 65, 110 [1892]), vessels made of Al may be used for holding articles of food, at least at the ordinary temperature, without danger of the metal being dissolved; this result is confirmed by Balland (*C. R.* 114, 1536 [1892]).

Aluminium, alloys of (vol. i. p. 143). For an alloy with *gold*, Al_2Au, *v.* Heycock a. Neville (*C. J.* 65, 74 [1894]).

Aluminium, chloride of (vol. i. p. 144). Nilson a. Pettersson (*Z. P. C.* 4, 206 [1889]) made a number of determinations of the V.D. of $AlCl_3$; they find that the compound gradually dissociates above its b.p. until c. 800°, when its V.D. becomes constant and corresponds with the formula $AlCl_3$. $AlCl_3$ may be prepared by heating an alloy of Al and Cu nearly to redness in dry HCl; $AlCl_3$ distils over unmixed with any Cu compound (Mabery, *B.* 22, 2658 [1889]). Sabatier (*Bl.* [3] 1, 88 [1889]) says that crystals of the hydrated chloride after being *in vacuo* for three months at 20° over H_2SO_4 have the composition $AlCl_3.6H_2O$.

Aluminium, oxides of (vol. i. p. 146). By heating Al_2O_3 with Mg, in the ratio Al_2O_3:Mg, Winkler (*B.* 23, 780 [1890]) obtained a brownish-black powder which, he says, contained a considerable quantity of an oxide lower than Al_2O_3, probably AlO. By the incomplete combustion of Al, Pionchon obtained a dark-grey powder, said by P. to have the composition $Al_8O_7 = 2Al_2O_3.Al_2O$ (*C. R.* 117, 328; *abstract* in *C. J.* 64 [11] 572 [1893]). By heating amorphous Al_2O_3 to incipient redness in HCl gas at a pressure of three atmos., Hautefeuille a. Perrey (*C. R.* 110, 1038 [1890]) obtained crystals of *corundum*. According to Read (*C. J.* 65, 313 [1894]), Al_2O_3 is unchanged at c. 1750°.

Aluminium, phosphide of (vol. i. p. 146). A grey crystalline powder, Al_3P_5, was obtained by Rossel a. Frank (*B.* 27, 52 [1894]) by heating Al in vapour of P, and then heating the product till P ceased to come off.

AMMONIA (vol. i. p. 196). *Formation.*—According to Loew (*B.* 23, 1443 [1890]), traces of NH_3 are formed by shaking Pt black with very dilute NaOHAq in the air. NH_3 is also formed by the combined action of Pt black and dextrose on KNO_3Aq (L., *l.c.*, p. 675).

Properties.—Ludeking a. Starr (*Am. S.* [3] 45, 200 [1892]) give S.H. of liquid NH_3 as ·8857. For measurements of the wave-lengths of the lines in the emission spectrum of NH_3 *v.* Magnanini (*Z. P. C.* 4, 435 [1889]). Perkin (*C. J.* 55, 689, 728 [1889]) gives M. M. of NH_3 in aqueous and alcoholic solutions; also Mol. R. of various NH_4 salts in solution. Tables showing the solubility of NH_3 in alcohol of various concentrations, at 10°, 20°, and 30°, are given by Delépine (*J. Ph.* [5] 25, 496; *v. abstract* in *C. J.* 62, 1049 [1892]). For the freezing-points of aqueous solutions of NH_3 *v.* Pickering (*C. J.* 63, 181 [1893]).

Reactions.—*Dry* NH_3 does not combine with *dry* hydrogen chloride when these gases are mixed (Baker, *C. J.* 65, 611 [1894]). Nor do *dry* NH_3 and *dry* carbon dioxide combine (Hughes a. Soddy, *C. N.* 69, 138 [1894]). Michel a. Grandmougin (*B.* 26, 2565 [1893]) say that the products of passing NH_3 over heated peroxide of Ba, Pb, Mn, or Ni, are N with a little HNO_2 and HNO_3, and oxide or hydroxide of the metal. The reactions of liquid NH_3 with $CrCl_3$ and $FeCl_3$ are described by Christensen (*Zeit. f. anorg. Chemie*, 4, 227; *abstract* in *C. J.* 64 [11] 469 [1893]).

AMMONIUM COMPOUNDS (vol. i. p. 200).

Ammonium amalgam (vol. i. p. 201). From measurements of the polarisation given by this substance in a solution of NH_4Cl against zinc amalgam, and a comparison of these measurements with the polarisations given by metallic amalgams, Le Blanc concludes that ammonium amalgam really exists (*Z. P. C.* 5, 467; *abstract* in *C. J.* 58, 1204 [1890]).

Ammonium chloride (vol. i. p. 202). Baker (*C. J.* 65, 611 [1894]) asserts that the V.D. of the *dry* salt at 350° is 28·7, corresponding with that required by the formula NH_4Cl. B. also says that no reaction occurs when *dry* NH_4Cl and *dry* CaO are heated together.

ANTIMONY (vol. i. p. 282). *Reactions.*—Montemartini (*G.* 22, 384, 426) finds that no appreciable quantity of NH_3 is formed by the interaction of Sb and HNO_3Aq varying from 2 to 70·3 p.c. HNO_3; NO_2 is practically the only gaseous product of the reaction; when 70 p.c. HNO_3Aq is used, the residue probably has the composition $(SbO)NO_3$.

Antimonates (vol. i. p. 285). Several salts have been prepared, by double decomposition from the K salt, by Beilstein and O. v. Bläse (*C. C.* 1889. 803; *abstract* in *C. J.* 56, 1123). All the compounds are salts of $HSbO_3$; B. a. B. conclude that the only well-marked antimonates are derived from this acid. Ebel (*B.* 22, 3044 [1889]) describes several metantimonates.

Antimonites (vol. i. p. 285). For antimonites of K and Na *v.* Cormimbœuf (*C. R.* 115, 1305; *abstract* in *C. J.* 64 [11], 171 [1893]).

Antimony, bromide of (vol i. p. 286). The b.p. of $SbBr_3$ is given as 275° by Freyer a. V. Meyer (*Zeit. f. anorg. Chemie*, 2, 1 [1892]).

Antimony, trichloride of (vol. i. p. 286). Boils at 223° (Freyer a. V. Meyer, *l.c.*).

Antimony, pentachloride of (vol. i. p. 287). The V.D. at 218° and 58 mm. pressure was found to be 141·7 (corresponding with the formula $SbCl_5$) by Anschütz a. Evans (*A.* 253, 95 [1890]). *Double compounds* of $SbCl_5$ with RbCl and CsCl are described by Saunders (*Am.* 14, 152 [1892]), and by Wheeler (*Am. S.* [3] 46, 269 [1893]).

Antimony, fluoride of (vol. i. p. 287). The *double compound* $SbF_3.2AmF$ is described by H. von Helmholt (*Zeit. f. anorg. Chemie*, 3, 115 [1893]).

Antimony, hydride of (vol. i. p. 288). The temperature whereat decomposition of SbH_3 begins is given by Brunn (*B.* 22, 3202 [1889]) as c. 150°. For the reactions of SbH_3 with $AgNO_3Aq$ *v.* Vitali (*abstract* in *C. J.* 64 [11], 206 [1893]).

Antimonic oxide (vol. i. p. 290). When heated to dull redness Sb_2O_5 gives off O, forming Sb_2O_4, which at c. 1750° is further reduced to Sb_2O_3 (Read, *C. J.* 65, 313 [1894]).

Antimonious sulphide (vol. i. p. 291). Black Sb_2S_3 is formed, according to Mitchell (*C. N.* 67, 291 [1893]), by passing CO_2 into boiling water with ordinary Sb_2S_3 in suspension. Picton (*C. J.* 61, 142 [1892]) obtained a colloidal Sb_2S_3 in very fine suspension in water, by allowing solution of tartar emetic to flow into saturated H_2SAq.

Antimony, thio-chlorides and thio-iodides of (vol. i. pp. 292 3). Ouvrard (*C. R.* 116, 1516 [1893]) describes SbSCl and $Sb_4S_5Cl_2$, obtained by the action of H_2S on $SbCl_3$; and SbSI formed by heating SbI_3 to 150° in dry H_2S, and $Sb_2S_3I_6$ formed by heating Sb_2S_3 with I and crystallising from CS_2.

ARSENIC (vol. i. p. 301). A full account of the different forms of As obtained, along with As_2O_3, by subliming As in a tube is given by Retgers (*Z. P. C.* 4, 403; *abstract* in *C. J.* 64 [11], 570 [1893]). Petersen gives the following heats of oxidation, and atomic volumes, of the allotropic forms of As (*Z. P. C.* 8, 601 [1891]):—

	$[As^2,O^3]$	At. volume
Grey, rhombohedric	156,830	13·1
Grey-black, amorphous	154,840	15·94
Brown, amorphous	163,506	15·99

Arsenic, bromide of (vol. i. 309). $AsBr_3$ combines with NH_3 to form $AsBr_3.3NH_3$ (Besson, *C. R.* 110, 1258 [1890]).

Arsenates (vol. i. p. 307). For arsenates of Cd *v.* A. de Schulten (*Bl.* [3] 1, 473 [1889]); for arsenates of Cu, and of Cu and Na, *v.* Hirsch (*C. C.* 1891 [1]. 15; *abstract* in *C. J.* 60, 644); many double arsenates of K, and of Na, with Cd, Co, Mg, Mn, Ni, and Zn are described by Lefèvre (*C. R.* 110, 405 [1890]).

For *thio-arsenates* of Cu, Hg, Zn, and Zn and Na, *v.* Preis (*A.* 257, 178 [1890]).

Arsenites (vol. i. p. 306). For the preparation, by double decomposition from the salt $2K_2O.As_2O_3$, and properties of the arsenites of the following metals *v.* Reichard (*B.* 27, 1019 [1894]):—Al, Ba, Cd, Ca, Cr, Co, Cu, Au, Fe, Pb, Mg, Mn, Hg, Ni, Pd, Pt, Ag, Sr, Sn, Ti, U, and Zn (references and criticisms of former investigations are given). Stavenhagen (*Zeit. f. angew. Chemie*, 1894, 165) obtained the *double salt* of K arsenite and sulphate, $K_3AsO_3.10K_2SO_4$, by evaporating solutions of the constituents after mixing.

Arsenic acid (vol. i. p. 307). For a detailed account of the reaction of H_2S with solutions of H_3AsO_4 *v.* Brauner a. Tomeetchek (*C. J.* 53, 145 [1888]).

Arsenious chloride (vol. i. p. 310). According to Besson (*C. R.* 109, 940 [1889]), $AsCl_3$ solidifies at −18°, forming white needles; at −30° $AsCl_3$ absorbs much Cl, forming a liquid which does not solidify at −60°, and which with water gives off much Cl and forms As_2O_3Aq. Besson (*C. R.* 110, 1258 [1890]) says that the compound formulated by Rose as $2AsCl_3.7NH_3$ is really $AsCl_3.4NH_3$.

Arsenious fluoride (vol. i. p. 310). Moissan (*A. Ch.* [6] 19, 280 [1891]) prepared AsF_3 by heating As_2O_3 with HF; he gives b.p. as 63° at 750 mm., and says that it solidifies to white crystals at −8·5°. Besson (*C. R.* 110, 1258 [1890]) describes the compound $2AsF_3.5NH_3$.

Arsenic, trihydride of (vol. i. p. 310). Brunn (*B.* 22, 3202 [1889]) finds that the first products of the action of air, or O, on AsH_3 are solid $nAsH$ and H_2O, and the next products are As and H_2O. AsH_3 and H_2S do not react in absence of air at the ordinary temperature either as gases or in solution (*B.*, *l.c.*). AsH_3 begins to decompose at c. 230° (*B.*, *l.c.*). For the reactions of AsH_3 with $AgNO_3Aq$ *v.* Vitali (*abstract* in *C. J.* 64 [11] 206 [1893]).

Arsenious iodide (vol. i. p. 311). Besson (*C. R.* 110, 1258 [1890]) describes the compounds $AsI_3.4NH_3$ and $AsI_3.12NH_3$.

Arsenious sulphide (vol. i. p. 315). Picton (*C. J.* 61, 140–144 [1892]) obtained an aqueous solution of colloidal As_2S_3, containing also some very finely divided sulphide in suspension, by allowing As_2O_3Aq to flow into saturated H_2SAq, into which H_2S was continually passing, and removing H_2S by a stream of H.

Arsenic pentasulphide (vol. i. p. 315) As_2S_5 is obtained, according to McCay (*Am.* 12, 547 [1891], by passing H_2S for a long time into a hot solution of an alkali dihydrogen arsenate, and then ppg. by a mineral acid.

Arsenic, thiochlorides and thio-iodides of (vol. i. p. 316). Ouvrard (*C. R.* 116, 1516 [1893]) obtained $As_4S_5Cl_2$ by passing H_2S into

$AsCl_3$, and washing the pp. with CS_2. By heating 1 pt. As_2S_3 with 10 pts. $AsCl_3$ to 150° he obtained AsSCl.

AZO-IMIDE (*v. Hydrazoic acid*, p. 919, *Addenda*).

BARIUM (vol. i. p. 440). Richards, in 1893, made an elaborate experimental revision of the at. w. of Ba (*P. Am. A.* 28, 1; 29, 55). As a mean result of the most trustworthy experiments, R. adopts 137·1 as the at. w. of Ba ($O = 15·96$). Limb (*C. R.* 112, 1434 [1891]) failed to obtain any Ba by electrolysing fused $BaCl_2$, or $BaCl_2$ mixed with NaCl.

Barium, carbide of. By heating a mixture of Ba amalgam and powdered charcoal in H, Maquenne (*C. R.* 114, 361 [1892]) obtained grey BaC_2; decomposed by water, giving BaO_2H_2Aq and C_2H_2; *v.* also Moissan, *C. R.* 118, 683 (*abstract* in *C. J.* 66 [1], 314 [1894]).

Barium, chloride of (vol. i. p. 441). By bringing $BaCl_2$ into contact with liquid NH_3, and allowing the gas to escape at 0° and 760 mm., Joannis obtained $BaCl_2.8NH_3$ (*C. R.* 112, 337 [1891]).

Barium, fluoride of (vol. i. p. 441). BaF_2 is obtained in microscopic crystals by adding $BaCl_2Aq$ (3·6 p.c.) to boiling KFAq (1 p.c.), boiling, washing, drying, and heating strongly (Moissan, *Bl.* [3] 5, 152 [1891]). Poulenc (*C. R.* 116, 987 [1893]) obtained BaF_2 in well-formed octahedra by fusing amorphous BaF_2 with KHF_2 and KCl.

Barium, nitrides of. Maquenne (*C. R.* 114, 220 [1892]) obtained a mixture, probably containing some Ba_3N_2, by heating Ba amalgam to redness in a current of N. Berthelot a. Matignon (*A. Ch.* (7) 2, 144 [1894]) say that BaN_6 is formed by heating AmN_3Aq with BaO_2H_2Aq.

Barium monoxide (vol. i. p. 442). BaO is unchanged at c. 1750° (Read, *C. J.* 65, 313 [1894]); it liquefies at c. 2,000°, but is not decomposed at c. 2,500° (Moissan, *C. R.* 115, 1034 [1892]).

Barium dioxide (vol. i. p. 443). BaO_2 is decomposed by salts of Al, Cr, Co, Fe, &c.; some salts—*e.g.* those of Ca, Li, K, Na—do not react with BaO_2 (*v.* Kwasnik, *B.* 25, 65). For decomposition of BaO_2 by heat *v.* Le Chatelier (*C. R.* 115, 654; *abstract* in *C. J.* 64 [11], 71 [1893]).

BERYLLIUM (vol. i. p. 504). Krüss a. Moraht (*B.* 23, 727 [1890]) obtained hexagonal crystals of Be, mixed with BeO, by heating $BeF_2.2KF$ to redness with Na. K. a. M. (*l.c.* p. 2552) obtained the value 9·03 for the at. w. of Be by converting BeO into $BeSO_4.4H_2O$, and this again to BeO. Gibson (*C. J.* 63, 909 [1893]) describes methods for preparing BeO from *beryl*.

Beryllium, fluoride of (vol. i. p. 506). Petersen (*Z. P. C.* 5, 263 [1890]) gives the thermal data H.F. $[BeO^2H^2, 2HFAq] = 19,$[illegible]83. The *double compound* $BeF_2.2AmF$ is described by H. von Helmholt (*Zeit. f. anorg. Chemie*, 3, 115 [1893]).

Beryllium, oxide of (vol. i. p. 506). By dissolving $BeO.x$aq in KOHAq, Krüss a. Moraht (*B.* 23, 727 [1890]) obtained *potassium beryllate* BeO_2K_2 (?), mixed with K_2CO_3, as a snow-white, silky solid.

BISMUTH (vol. i. p. 509). The at. w. of Bi was re-determined by Classen in 1890 (*B.* 23, 938 [1890]), by converting Bi into nitrate, and this into Bi_2O_3; the mean result was 208·80 ($O = 15·96$). Schneider (*J. pr.* [2] 42, 553; 44, 23 [1891]) criticises Classen's results, and maintains that Marignac's value (almost exactly 208) is as trustworthy as that obtained by C. The molecule of Bi in dilute solution in tin is perhaps diatomic (?) (Heycock a. Neville, *C. J.* 57, 376 [1890]).

Preparation.—Classen (*l.c.*) says that pure Bi is best prepared by electrolysing a solution of the metal in HNO_3Aq, using a cone of Pt as the negative electrode, then washing with alcohol, and fusing with KCy.

Properties.—Melts at 264°, according to Classen (*l.c.*); at 269·22°, according to Callendar a. Griffiths (*C. N.* 63, 1 [1891]). S.G. 9·7474 (C., *l.c.*; no temperature given); 9·787 at $\frac{0°}{4°}$, 9·673 solid at the m.p., 10·004 liquid at the m.p. (Vicentini, *Rend. Acad. Lincei*, 6 [11], 121, 147 [1891]). For S.G. of liquid Bi from 235° to 280° *v.* Cattaneo (*Rend. Acad. Lincei*, 7 [11], 88 [1892]). For electrical resistance *v.* E. v. Aubel (*C. R.* 108, 1102 [1889]).

Reactions.—According to Veley (*Pr.* 48, 458 [1891]), Bi does not dissolve in 30 p.c. HNO_3Aq at 30° if HNO_2 is absent; but Bi dissolves readily in 1 p.c. HNO_2Aq.

Bismuth, bromide of (vol. i. p. 511). $BiBr_3$ boils at 453° (V. Meyer, *A.* 264, 122 [1891]). Cavazzi a. Tivoli (*G.* 21 [11], 306 [1892]) describe a lustrous, black, hygroscopic solid, $PBrH(BiBr_2)_3$, obtained by allowing $BiBr_3$ to fall gradually into PH_3 (*abstract* in *C. J.* 62, 279).

Bismuth, chloride of (vol. i. p. 512). Boils at 435°–441° (uncor.) (V. Meyer, *l.c.*). The only *double chloride* of Bi and K of those hitherto described that exists is $BiCl_3.2KCl.2aq$, according to Brigham (*Am.* 14, 164 [1892]). B. has also prepared $BiCl_3.KCl.aq$.

Bismuth, fluoride of (vol. i. p. 512). H. von Helmholt describes the *double fluoride* $BiF_3.AmF$ (*Zeit. f. anorg. Chemie*, 3, 115 [1893]).

Bismuth, iodide of (vol. i. p. 513). Astre (*C. R.* 110, 525 [1890]) obtained the *double iodide* $2BiI_3.KI$ by keeping I, KCl, Bi, and water in contact for some weeks, and then crystallising from Et acetate.

Bismuthous oxide (vol. i. p. 513). Classen (*B.* 23, 938 [1890]) gives S.G. as 9·044. Read (*C. J.* 65, 313 [1894]) found Bi_2O_3 to be unchanged at c. 1750°.

Bismuth, oxysulphide of (vol. i. p. 516). By passing dry H_2S into boiling benzene containing Bi_2O_3 in suspension, P. v. Scherpenberg (*C. C.* 1889. [11] 643) obtained Bi_2O_2S.

Bismuth, selenide of (vol. i. p. 516). The *double compound* $Bi_2Se_3.K_2Se$ is described by P. v. S. (*l.c.*).

Bismuth, sulphide of (vol. i. p. 516). P. v. S. (*l.c.*) obtained the *double compound* $Bi_2S_3.K_2S$ by fusing Bi_2O_3 with K polysulphide.

BORON (vol. i. p. 524). The at. w. of B has been determined by Abrahall by the analysis of BBr_3 (*C. J.* 61, 650 [1892]); the value obtained was 10·67 ($O = 15·96$). Also by Ramsay a. Aston (*C. J.* 63, 207 [1893]) by finding the percentage of water in crystallised borax, and by distilling fused borax with HClAq and $CH_3.OH$ and weighing the residual NaCl; the values varied about 11, but showed considerable differences.

Rimbach (*B.* 26, 164 [1893]), by titrating solutions of borax with standard HClAq, using methyl orange as indicator, obtained the value 10·91 (O = 15·96). The following values for S.H. of amorphous B are given by Moissan a. Gautier (*C. R.* 116, 924 [1893]): 0° to 100° = ·3066, 0° to 192° = ·3407, 0° to 234° = ·3573. For atomic refraction of B *v.* Ghira (*G.* 23 [1], 452; *abstract* in *C. J.* 64 [11], 517 [1893]).

Preparation.—According to Moissan (*C. R.* 114, 319 [1892]), the methods employed to give *amorphous boron* yield substances containing from c. 45 to c. 72 p.c. of B. M. (*l.c.* p. 392) says that nearly pure amorphous B is obtained by heating to redness a mixture of one pt. powdered Mg with 3 pts. fused B_2O_3, washing with HClAq, KOH in alcohol, HFAq, and water (the process is tedious, details are given); by fusing this product with 50 pts. B_2O_3, and washing with HClAq &c., a brown powder is obtained containing c. 98·5 p.c. B, with traces of Mg and small quantities of other impurities.

Properties and Reactions.—The properties of *amorphous boron* are described by Moissan (*C. R.* 114, 617 [1892]). Brown powder; S.G. 2·45. Does not fuse in electric arc, but volatilises (M., *C. R.* 117, 423 [1893]); increases in density when heated to c. 1500° in H. Specific electrical resistance = 801 megohms. Burns in air at c. 700°. Combines directly with Br, Cl, (not I), N at c. 1200°, Se, S, (not Te); also with Al, Fe, Mg, Pt, and Ag. Reduces many oxyacids and oxides when heated therewith; $HClO_3$, HIO_3, HNO_3, and H_2SO_4 are readily reduced; As_2O_3 and As_2O_5, CO, N_2O, P_2O_5, SiO_2, steam, and SO_2 are also reduced; many metallic oxides are reduced to metals, often with explosive violence; molten KOH gives off H; metallic fluorides are generally decomposed, giving BF_3; many other metallic salts, both in solution and when heated as solids, are reduced by amorphous boron.

Boron, bromide of (vol. i. p. 525). BBr_3 boils at 90° (Freyer a. V. Meyer, *Zeit. f. anorg. Chemie*, 2, 1). Ghira (*Z. P. C.* 12, 768 [1893]) gives S.V. 94·72; and S.G. $\frac{0^\circ}{4^\circ}$ = 2·64985. According to Besson (*C. R.* 112, 1001 [1891]), when a mixture of gaseous HI and BBr_3 is passed through a glass tube at 300°-400° the products are BBr_2I, $BBrI_2$, and BI_3. BBr_2I and $BBrI_2$ are colourless liquids, distilling at c. 125° and 180°; they are rapidly decomposed by air and light. Tarible (*C. R.* 116, 1521 [1893]) says that BBr_3 combines with PBr_3 and PBr_5 to form compounds easily decomposed by water, Cl, or NH_3 in the cold. Besson (*C. R.* 114, 542 [1892]) describes $BBr_3.4NH_3$, obtained by passing dry NH_3 into BBr_3 in dry CCl_4 at 0°.

Boron, carbide of, B_6C. Moissan (*C. R.* 118, 556 [1894]) says that B and C combine when amorphous B is mixed with c. $\frac{1}{5}$ its weight of sugar charcoal, and the mixture is heated in the electric furnace for some minutes, using a current of 250-300 ampères and 70 volts. After treating the product with HNO_3Aq, and then with $KClO_3$ and HNO_3Aq, the carbide remains as a very hard, lustrous, black, crystalline powder; S. G. 2·51; burns very slowly in O at c. 1000°; acted on by Cl below 1000°, but not by Br, I, S, P, N, or mineral acids; reacts with molten KOH or $KNaCO_3$ (*abstract* in *C. J.* 66 [11], 279 [1894]).

Boron, chloride of (vol. i. p. 525). BCl_3 boiling at 17° (Freyer a. V. Meyer, *Zeit. f. anorg. Chemie*, 2, 1). Ghira (*Z. P. C.* 12, 768 [1893]) gives S.G. $\frac{0^\circ}{4^\circ}$ = 1·43386, and S.V. 81·94.

Boron, fluoride of (vol. i. p. 526). According to Besson (*C. R.* 110, 80 [1890]), BF_3 unites with PH_3 at c. −30° to form $2BF_3.PH_3$, decomposed by water giving off H and PH_3.

Ammonium borofluoride is described by Stolba (*C. C.* 1890. [1] 211; *abstract* in *C. J.* 58, 560).

Boron, hydride of (vol. i. p. 526). Sabatier (*C. R.* 112, 865 [1891]) says that the gas produced by adding HClAq to the brown powder formed by heating B_2O_3 with Mg in H has a very disagreeable odour, burns with a green flame, gives a brown pp. with $AgNO_3Aq$, deposits B when passed through a glass tube at a dull red heat (H coming off), and is decomposed by electric sparks, giving pure H. The gas contains a little B hydride, according to S. (*l.c.*); *cf.* Winkler (*B.* 23, 772 [1890]).

Boron, iodide of (vol. i. p. 527). BI_3. Prepared by Moissan (*C. R.* 112, 717 [1891]), (1) by heating I and B to 700°-800°; (2) by heating amorphous B (dried in H at 200°), in a stream of dry HI, in a tube of hard glass until the glass nearly softens; (3) by passing HI and BCl_3 vapours through a porcelain tube heated to redness. The product is dissolved in CS_2, shaken with Hg, and allowed to crystallise. Colourless crystals, very hygroscopic, rapidly become coloured in light. Melts at 43° and boils at 210°. Decomposed by water, giving HIAq and H_3BO_3Aq. (For other reactions *v. abstract* in *C. J.* 60, 979 [1891].) For compounds with NH_3 *v.* Besson (*C. R.* 114, 542 [1892]; *abstract* in *C. J.* 62, 771).

Boron, oxide of (vol. i. p. 527), B_2O_3. For reduction by Mg powder, giving Mg boride, *v.* Winkler (*B.* 23, 772 [1890]). The compound $B_2O_3.P_2O_5$ (= BPO_4) is obtained by evaporating H_3BO_3Aq mixed with H_3PO_4, heating to redness, and washing with hot water (G. Meyer, *B.* 22, 2919 [1889]).

Borates (vol. i. p. 529). For some new borates of Li, Rb, and Cs *v.* Reischle (*Zeit. f. anorg. Chemie*, 4, 166 [1893]). For remarks on the classification of alkali and alkaline earth borates *v.* Le Chatelier (*C. R.* 113, 1034 [1891]). For a full account of Mn borate, *v.* Hartley a. Ramage (*C. J.* 63, 129 [1893]). The compounds $6FeO.FeBr_2.8B_2O_3$ and $6ZnO.ZnBr_2.8B_2O_3$ are described by Rousseau a. Allaire (*C. R.* 116, 1445; *abstract* in *C. J.* 64 [11], 518 [1893]).

Boron, phosphide of. According to Besson (*C. R.* 113, 78 [1891]), a phosphide of B is obtained by passing PH_3 into BBr_3, and heating the product, $BBr_3.PH_3$, to 300°, when it gives HBr and B phosphide. The phosphide is said to be a brown powder, insoluble in water, reacting with boiling conc. alkali solutions to give PH_3; gives off P when heated to redness in N (for other reactions *v. abstract* in *C. J.* 60, 1418 [1891]).

Boron, selenide of. (?B_2Se_3). Obtained, as a yellowish grey powder, decomposed violently by water, giving H_2Se and some Se, by heating B to full redness in a current of H_2Se (Sabatier, *C. R.* 112, 1000 [1891]).

Boron, sulphides of (vol. i. p. 531). For heat of formation of B_2S_3 *v.* Sabatier (*C. R.* 112, 862; *abstract* in *C. J.* 60, 981 [1891]). Moissan (*C. R.* 115, 203 [1892]) gives details of various methods of preparing B_2S_3, and describes the reactions of this compound (*v. abstract* in *C. J.* 62, 1393 [1892]). According to M. (*l.c.* p. 271), *boron pentasulphide*, B_2S_5, is obtained by heating BI_3 with rather less than one equiv. of S in CS_2 solution at 60° for many hours. M. describes the compound, which was not obtained pure, as a light white crystalline powder. S.G. 1·85.

BROMHYDRIC ACID (vol. i. p. 532). The V.D. has been determined by Biltz at $-15°$ and $-28°$ (*Z. P. C.* 10, 354 [1892]); the results agree with the V.D. required by the formula HBr. The M. M.s of HBrAq from 15·47 to 65·59 p.c. HBr have been measured by Perkin (*C. J.* 55, 706 [1889]).

Preparation.—1. By the interaction of P, Br, and H_2O, *v.* Fileti a. Crosa (*G.* 21, 64 [1891]; *cf.* Gassman, *abstract* in *C. J.* 64 [11], 453 [1893]). 2. By passing H_2S into Br covered with water (Recoura, *C. R.* 110, 784 [1890]).—3. By adding H_2SO_4Aq S.G. 1·41 to KBr (Feit a. Kubierschky, *J. Ph.* [5] 24, 159; *abstract* in *C. J.* 60, 1320 [1891]; *v.* also Addyman, *C. J.* 61, 97 [1892]; *cf.* Léger, *abstract* in *C. J.* 64 [11], 114 [1893]).

Hydrates.—Pickering (*P. M.* [5] 36, 11 [1894]) has isolated $HBr.3H_2O$ and $HBr.4H_2O$; the former melting at $-48°$ and the latter at $-55·8°$.

Reactions.—For the decomposition of HBrAq by H_2SO_4Aq of different concentrations *v.* Addyman (*C. J.* 61, 98 [1892]).

BROMINE (vol. i. p. 534). Mol. w. in solution in water or acetic acid = 159·5 (Br_2) (Paterno a. Nasini, *B.* 21, 2153 [1888]). The V.D.s of Br from 15° to 280°, and at pressures from 75 to 760 mm., have been determined by Perman (*Pr.* 48, 45 [1891]); no indications of dissociation were obtained. For measurements of the absorption of light by Br *v.* Camichel (*C. R.* 117, 807; *abstract* in *C. J.* 64 [11], 561 [1893]).

Bromates (vol. i. p. 538). *Lithium bromate* $LiBrO_3$; prepared by the interaction of $Ba(BrO_3)_2Aq$ and Li_2SO_4Aq (Potilitzin, *J. R.* 22, 392; *abstract* in *C. J.* 62, 1275 [1892]). *Potassium bromate* $KBrO_3$. The decomposition of this salt by heat has been studied by Cook (*C. J.* 65, 802 [1894]); decrepitation occurs at c. 180°, with evolution of Br; the salt fuses at a higher temperature, and O is evolved, without any Br, until KBr remains; no oxy- compounds are formed.

Strontium bromate begins to decompose at c. 240°; the principal change is to $SrBr_2$ and O, but SrO is also formed (Potilitzin, *J. R.* 22, 454; *abstract*, with summary of *quantitative results*, in *C. J.* 64 [11], 11 [1893]).

CADMIUM (vol. i. p. 354) Determinations of the at. w. have been made by Partridge (*Am. S.* [3] 40, 377 [1891]), and by Morse a. Jones (*Am.* 14, 261 [1892]). P. converted CdC_2O_4 into CdO by heating, $CdSO_4$ into CdS by heating in H_2S, and CdC_2O_4 into CdS by heating in H_2S. M. a. J. converted Cd into $Cd(NO_3)_2$, and this into CdO by heating. The results all lie about 112 (*v. abstract* in *C. J.* 60, 399; *cf.* Clarke, *ibid.* 390 [1891], and 62, 1397 [1892]). Lorimer a. Smith (*Zeit. f. anorg. Chemie*, 1, 364 [1892]) obtained values varying from 112·182 to 111·908 (O = 16). The molecule of Cd in dilute solution in tin may be diatomic (*v.* Heycock a. Neville, *C. J.* 57, 376 [1890]). Cd melts at 320·68°, according to Callendar a. Griffiths (determined by Pt thermometer, *C. N.* 63, 1 [1891]). For the line-spectrum of Cd *v.* Ames (*P. M.* [5] 30, 33 [1890]). According to Williams (*Am.* 14, 273 [1892]), Cd crystallises in hexagonal and polyhedral forms; axial ratio $a:c = 1:1·6554$. Cd is superficially oxidised at a dull-red heat by *nitric oxide* (Sabatier a. Senderens, *C. R.* 114, 1429 [1892]). Montemartini (*G.* 22 [1] 250; *v. abstract* in *C. J.* 62, 1278 [1892]) has analysed the gases produced by the interaction of Cd and nitric acid; with excess of HNO_3Aq (27·5 p.c.) at 8°, N, NO, N_2O and NH_3 are produced.

Cadmium, alloys of (vol. i. p. 655). For an alloy with *gold*, CdAu, *v.* Heycock a. Neville (*C. J.* 61, 914 [1892]; *cf. ibid.* 65, 65 [1894]). For alloys with *copper*, *gold*, and *silver*, prepared by immersing Cd in solutions of salts of the other metals, *v.* Mylius a. Fromm (*B.* 27, 630 [1894]).

Cadmium, bromide of (vol. i. p. 655). For the *double compounds* $CdBr_2.xCsBr$, $x = 1, 2$, and 3, *v.* Wells a. Walden (*Zeit. f. anorg. Chemie*, 5, 266 [1893]).

Cadmium, chloride of (vol. i. p. 655). Kwasnik (*Ar. Ph.* 229, 569; *abstract* in *C. J.* 62, 566 [1892]) describes $CdCl_2.2NH_3$ and $CdCl_2.NH_3$. For the *double compounds* $CdCl_2.CsCl$ and $CdCl_2.2CsCl$, *v.* Wells a. Walden (*l.c.*). *Double compounds* with HCl, NH_4Cl, LiCl, and KCl, of the form $CdCl_2.MCl.xaq$, are described by Chassevant (*A. Ch.* [6] 30, 5; *v. abstract* in *C. J.* 66 [11], 18 [1894]).

Cadmium, fluoride of (vol. i. p. 655). CdF_2 is obtained by (1) the interaction of HF and Cd at a red heat; (2) the interaction of HF and fused $CdCl_2$, or CdO at a red heat; it is a colourless, transparent solid; S.G. 6·64; somewhat soluble water, insoluble alcohol of 95° (Poulenc, *C. R.* 116, 581 [1893]).

Cadmium, iodide of (vol. i. p. 656). For the *double compounds* $CdI_2.xCsI$, when $x = 1, 2$, and 3, *v.* Wells a. Walden (*l.c.*).

Cadmium, oxides of (vol. i. p. 656). CdO is unchanged at c. 1750° (Read, *C. J.* 65, 313 [1894]).

According to Kouriloff (*J. R.* 22, 171; *abstract* in *C. J.* 62, 1278 [1892]), the compound $CdO_2.CdO_2H_2$ is obtained by heating CdO_2H_2 with H_2O_2Aq. Morse a. Jones (*Am.* 12, 488; *abstract* in *C. J.* 58, 1376 [1890]) obtained small crystals, which they say were cadmous oxide Cd_2O, by gently heating CdOH; the hydroxide was obtained by heating $CdCl_2$, $CdBr_2$, or CdI_2, with excess of Cd, to the melting-point, in N, or *in vacuo*, and treating with water, when $CdCl_2$, $CdBr_2$, or CdI_2 dissolved, a little CdO_2H_2 separated, and CdOH remained as a white amorphous powder.

Cadmium, salts of (vol. i. p. 656). For the electrical conductivities of very dilute solutions of $CdBr_2$, $CdCl_2$, CdI_2, K_2CdI_4, $Cd(NO_3)_2$, and $CdSO_4$, *v.* Wershoven (*Z. P. C.* 5, 481 [1890]).

Cadmium, sulphide of (vol. i. p. 657). Two forms (and perhaps more) of CdS seem to exist, one lemon-yellow and the other red; they differ slightly in S.G., and in crystalline form; the yellow is said to change to the red by friction (*v.* Buchner, *Chem. Zeit.* 11, 1087, 1107; 15, 778; von Klobukoff, *J. pr.* [2] 39, 412; *abstracts* in *C. J.* 54, 224 [1888]; 56, 946 [1889]; 62, 778 [1892]). A solution of colloidal CdS was obtained by Prost (*C. C.* 1888. 32; *abstract* in *C. J.* 54, 653 [1888]) by completely ppg. an ammoniacal solution of $CdSO_4$ by H_2S, washing well, suspending the pp. in water and passing in H_2S. A solution with 4 grms. CdS per litre remained clear for many days; one with 11 grms. coagulated in 24 hours.

CÆSIUM (vol. i. p. 657). According to Beketoff (*v. abstract* in *C. J.* 62, 274 [1892]), Cs is obtained by heating CsOH with c. ¼ its weight of Al.

Cæsium, haloid compounds of (vol. i. p. 658). A series of compounds of the form CsX_3, where $X_3 = Br_3$, I_3, or Br and I, Cl, Br and I, &c., is described by Wells a. Penfield (*Am. S.* [3] 43, 17; *abstract* in *C. J.* 62, 773 [1892]). *Double compounds* of Cs haloids with haloid compounds of Cd, Cu, Mg, Hg, Pb, and Zn are described by Wells (and others) (*Am. S.* [3] 44, 221; *Zeit. f. anorg. Chemie*, 3, 195; 5, 266, 273, 300, 304, 306; *abstracts* in *C. J.* 64 [11], 67, 322 [1893]; 66 [11], 45, 47 [1894]).

Cæsium, hydroxide of (vol. i. p. 658). S.G. $\frac{0°}{4°}$ 4·0178; [CsOH,Aq] = 15,876; [CsOHAq,HClAq] = 13,790 (Beketoff, *C. C.* 1891. [11] 451).

Cæsium, oxide of (vol. i. p. 658). According to Beketoff (*J. R.* 25, 433; *abstract* in *C. J.* 66 [11], 234 [1894]), Cs_2O reacts with slightly moist H to give Cs and CsOH.

CALCIUM (vol. i. p. 663). The molecule in dilute solution in tin may be diatomic (*v.* Heycock a. Neville, *C. J.* 57, 376 [1890]).

Calcium, carbide of. By heating 120 g. $CaCO_3$ with 70 g. sugar charcoal in the electric furnace with a current of 350 ampères and 70 volts, Moissan (*C. R.* 118, 501 [1894]) obtained lustrous, yellow crystals of CaC_2; S.G. 2·22 at 18°; insoluble in most solvents; reacts with Cl, Br, and I at 250°–350°; burnt to $CaCO_3$ by O at a red heat; interacts violently with water, giving off pure acetylene, and with steam giving $CaCO_3$, C, H, and C_2H_2 (*abstract* in *C. J.* 66 [1], 313 [1894]).

Calcium, oxide of (vol. i. p. 666). CaO is unchanged at c. 1750° (Read, *C. J.* 65, 313 [1894]). According to Veley (*C. J.* 63, 821 [1893]; 65, 1 [1894]), *dry* CaO does not appreciably combine with *dry* CO_2, SO_2, or Cl below 300°. Baker (*C. J.* 65, 611 [1894]) says that *dry* CaO does not react with *dry* SO_3, nor with *dry* NH_4Cl. Moissan (*C. R.* 115, 1034 [1892]) obtained crystals of CaO by heating ordinary lime in the electric furnace.

Calcium, oxychloride of (vol. i. p. 666). Prepared by boiling CaO with conc. $CaCl_2Aq$; crystallises in thin, lustrous needles; decomposed by water, alcohol, &c.; dissolves in glycerin. Composition is probably $3CaO.CaCl_2.15aq$ (Zahorsky, *Zeit. f. anorg. Chemie*, 3, 34 [1893]).

Calcium, oxyiodide of. By heating CaO with CaI_2Aq in a sealed tube at 150° for 6 hours, Tassilly (*Bl.* [3] 9, 629 [1893]) obtained needles of $CaI_2.3CaO.16aq$.

CARBON (vol. i. p. 684).

Diamond. Moissan (*C. R.* 116, 218; 118, 320; *abstracts* in *C. J.* 64 [11], 275; 66 [11], 189 [1893 and 1894]) obtained grey-black *carbonado* by dissolving C in iron, heating to 2000°–3000°, and rapidly cooling the exterior by water or by plunging into a bath of melted lead; the liquid interior expands as it cools and produces a very high pressure. Diamond blackens, swells, and changes to graphite in the electric furnace (M., *C. R.* 117, 423 [1893]). For various reactions of diamond, *v.* Moissan (*C. R.* 116, 460; *abstract* in *C. J.* 64 [11], 319 [1893]).

Graphite. For accounts of graphites prepared in different ways, the compositions of the graphitic oxides obtained, and the H.F.s of these oxides, *v.* Berthelot a. Petit (*C. R.* 110, 101, 106; *abstract* in *C. J.* 58, 448 [1890]). For the action of conc. HNO_3 on various graphites, *v.* Luzi (*B.* 24, 4085; 26, 1412 [1892 and 1893]).

Amorphous carbon. Mixter (*Am. S.* [3] 45, 363; *abstract* in *C. J.* 64 [11], 571 [1893]) describes the interactions of charcoal and N, S, O, and the halogens. According to Ernst (*J. pr.* [2] 48, 31; *abstract* in *C. J.* 64 [11], 461 [1893]), the composition of the products of combustion of coke (CO and CO_2) depends almost wholly on the temperature; the maximum formation of CO_2 is at c. 700°, at 1,000° CO is the only product.

Allotropy of carbon. The following heats of combustion, and atomic volumes, are given by Petersen (*Z. P. C.* 8, 601 [1891]):—

	$[C,O^2]$.	At. volume.
Amorphous .	96,530 to 96,980	6·7 to 8
Graphite . . .	93,360	5·3
Diamond . . .	93,240 to 94,550	3·4

For the reactions of various forms of C with $K_2Cr_2O_7$ and H_2SO_4 *v.* Wiesner (*M.* 13, 871; *abstract* in *C. J.* 62, 1273 [1892]); and with HNO_3 and $KClO_3$ *v.* Schutzenberger (*C. R.* 111, 774; *abstract* in *C. J.* 60, 265 [1891]).

Carbon, tetrabromide of (vol. i. p. 688). Collie (*C. J.* 65, 262 [1894]) finds that very many compounds of carbon give CBr_4 when heated with NaOHAq and Br.

Carbon, bromochorides of (vol. i. p. 688). The three compounds $CBrCl_3$, CBr_2Cl_2, and $CBrCl_3$ are formed by heating $CHCl_3$ and Br to 225° in a sealed tube (Besson, *C. R.* 114, 222 [1892].)

Carbon, tetrafluoride of, CF_4. Mol. w. 88·37. V.D. 44·6. Prepared by the direct union of C (purified lampblack) and F at the ordinary temperature; by the reaction of F with CCl_4 slightly heated, or with $CHCl_3$ at 100°, or with CH_4 (Moissan, *C. R.* 110, 296, 951; *abstracts* in *C. J.* 58, 557, 944 [1890]); also by heating AgF with CCl_4 to 220° in a sealed tube (Chabrié, *C. R.* 110, 279 [1890]). M. recommends to pass vapour of CCl_4 over AgF at 195°–200°, to let the vapours pass through a serpentine tube kept at −23°, and to collect the gas over Hg; the gas is kept in contact with fragments of caoutchouc (to remove CCl_4), then shaken with absolute alcohol, in which it dissolves, and then expelled by heat, collected and shaken with H_2SO_4 (to remove alcohol vapour); metal vessels must be used. CF_4 is a colourless gas, liquefying at −15° and 760 mm. pressure, or at 20° under a pressure of 4 atmos. Other fluorides seem to be formed along with CF_4; Chabrié (*l.c.*) says that AgF and C_2Cl_4 yield C_2F_4.

Carbon, tetra-iodide of (vol. i. p. 689). Moissan (*C. R.* 113, 19; *abstract* in *C. J.* 60, 1420 [1891]) prepares CI_4 by heating CCl_4 (free from $CHCl_3$) with excess of BI_3 to 90° in a sealed tube, washing the crystals with $NaHSO_3Aq$, drying, and slowly subliming *in vacuo*. CI_4 reacts with Cl to form CCl_4 and chlorides of I; reduced to CHI_3 by H at 140° (for other reactions *v.* M., *l.c.*).

Carbon monoxide (vol. i. p. 689). For some experiments on the sparking of CO, with the formation of brown solids, *v.* Berthelot (*C. R.* 110, 609) and Schützenberger (*C. R* 110, 560; *abstracts* in *C. J.* 58, 691 [1890]). Winkler (*B.* 24, 873 [1891]) finds that CO is reduced to C, at a full red heat, by Mg; carbides of Mg are probably formed (*cf.* W., *B.* 23, 2642 [1890]).

Carbon dioxide (vol. i. p. 691). For S.H. of CO_2 *v.* Kurnakoff (*J. R.* 22, 493; *abstract* in *C. J.* 64 [11], 5 [1893]). CO_2 is reduced by heating to redness with Mg, amorphous C and some CO being formed (Winkler, *B.* 23, 2642; 24, 873 [1890-91]). *Dry* CO_2 is said not to combine with *dry* NH_3 (Hughes a. Soddy, *C. N.* 69, 138).

Carbon, oxychloride of (vol. i. p. 692). $COCl_2$ becomes viscid, but remains clear, at −75° (Haase, *B.* 26, 1052 [1893]).

Carbon disulphide (vol. i. p. 693). The contractions observed when mixtures of CS_2 and air are exploded show that the reaction is more complicated than is shown by the equation $CS_2 + 3O_2 = CO_2 + 2SO_2$; the volume of CO_2 found is, practically, in accordance with the equation, but the volume of SO_2 is smaller; some of the N of the air is oxidised (*v.* Pedler, *C. J.* 57, 625 [1890]). By heating CS_2 with excess of *aqua regia*, Schlagdenhauffen a. Bloch (*J. Ph.* [5] 28, 241 [1893]) obtained $SO(OCCl_3)Cl$. Decomposition of CS_2, heated in dry N, begins at 216°, and explosion with O at a higher temperature (Baker, *C. J.* 65, 611 [1894]).

Tricarbon disulphide C_3S_2. B. von Lengyel (*B.* 26, 2960 [1893]) obtained this compound by keeping the vapours of CS_2 in an electric arc between C poles for some hours, filtering off the black substance formed, allowing the red filtrate to stand over Cu for 6 to 8 days, and evaporating in a current of dry air. C_3S_2 is a deep-red liquid, S.G. 1·27389; the vapour, even in minute quantities, causes violent catarrh; can be distilled, with partial change to a black solid, at 60°–70° and reduced pressure; insoluble water, but dissolved by EtOH, Et_2O, CS_2, $CHCl_3$, or C_6H_6. A conc. solution in CS_2 deposits a black solid; the same solid is formed by gently heating the liquid, if heating to 100°–120° is rapid the change is explosive. The black solid is probably a polymeride. A solution of C_3S_2 in CS_2 reacts with Br to form $C_3S_2Br_6$. (For other reactions, *v. abstract* in *C. J.* 66 [11], 91 [1894].)

Carbon, thiobromide of, $C_3S_2Br_6$; formed by the action of Br on a solution of C_3S_2 in CS_2 (*v. supra*).

Carbon, thiochloride of (vol. i. p. 695). The polymeride of thio-carbonyl chloride has the molecular formula $(CSCl_2)_2$, according to the cryoscopic determinations of Carrara (*G.* 23 [ii.] 12; *abstract* in *C. J.* 66 [11], 15 [1894]).

CERIUM (vol. i. p. 723). For details regarding the preparation of Ce compounds free from compounds of Di and La, *v.* Schottländer (*B.* 25, 378 [1892]); also Bricout (*C. R.* 118, 145 [1894]).

Cerium, hydride of. According to Winkler (*B.* 24, 873 [1891]), a compound of Ce and H, probably CeH_2, is formed by reducing CeO_2 by Mg in presence of H.

Cerium dioxide (vol. i. p. 725). CeO_2 is unchanged at c. 1750° (Read, *C. J.* 65, 313 [1894]).

CHLORHYDRIC ACID (vol. ii. p. 5). Biltz (*Z. P. C.* 10, 354 [1892]) finds that the V.D. at −77° agrees with the formula HCl. Perkin (*C. J.* 55, 703, 705 [1889] has determined M. M. of HClAq and HCl in iso-amyl oxide; the values obtained for HCl in Aq are c. double those for HCl in iso-amyl oxide. For measurements of the E.C. of HCl in different solvents, *v.* Kablukoff (*Z. P. C.* 4, 429 [1889]). For revised tables giving S.G. of HClAq, *v.* Lunge a. Marchlewski (*Zeit. f. anorg. Chemie*, 1891. 133).

For the relations between the number of molecules of HCl required to ppt. one mol. of different chlorides, and the reduction of the freezing-points of solutions of the chlorides and of HCl, *v.* Engel (*C. R.* 117, 845; *abstract* in *C. J.* 66, 40 [1894]).

Bailey a. Fowler (*C. J.* 53, 755 [1888]) find that when HCl stands over P_2O_5 the gas is absorbed, with production of $POCl_3$ and HPO_3; and that when HCl and O stand over Hg an oxychloride, probably $Hg_2OCl_2.H_2O$, is formed. Baker (*C. J.* 65, 611 [1894]) states that *dry* HCl does not combine with *dry* NH_3 when the gases are mixed.

CHLORINE (vol. ii. p. 10). For the S.G. of *liquid chlorine* from −80° to 77°, and the vapour pressures from −88° to 146°, *v.* Knietsch (*A.* 259, 100 [1890]). For the preparation of Cl for use in the laboratory, *v.* Klason (*B.* 23, 330; *abstract* in *C. J.* 58, 445 [1890]). Shenstone (*C. J.* 61, 445 [1892]) finds that Cl obtained by heating $PtCl_4$ always contains some HCl and O, with water, and perhaps a trace of N. Cl expands when brought into sunlight. Richardson (*P. M.* [5] 32, 277 [1891]) has constructed an instrument wherein the expansion is used to measure the intensity of light. Baker (*C. J.* 65, 611 [1894]) found that no explosion occurred when a mixture of equal vols. of *dry* Cl and *dry* H was exposed to bright sunlight; and that after exposure to bright sunshine for two days, and to diffused light for two days, more than a quarter of the mixture remained unchanged.

Pedler (*C. J.* 57, 613 [1890]) has examined the interaction of Cl and water in tropical sunlight; he finds that there is very little action, unless there is an extremely large excess of water. With very much water and little Cl, exposed to the full light of the sun in the hot season in India, the main reaction is $2H_2O + 2Cl_2 + Aq = 4HClAq + O_2$; with diffused sunlight HClAq and HClOAq are formed at first, and finally HClAq, $HClO_3Aq$, and O. Harker (*Z. P. C.* 9, 673 [1892]), from an extended investigation of the explosion of mixtures of Cl, H, and O, concluded that when there is insufficient H to combines with all the Cl and all the O, a division of the H between the Cl and O occurs; and that the product of the numbers of molecules of HCl and O, divided by the product of the numbers of molecules of H_2O and Cl_2 is a constant, or, in other words, that the law of Guldberg a. Waage holds good. According to Gautier a. Charpy (*C. R.* 113, 597 [1891]), there is no reaction between Mg or Zn and liquid Cl at the ordinary temperature, very little reaction with Fe or Ag, and rather more with Cu.

Chlorates (vol. i. p. 18). Spring a. Prost (*Bl.* [3] 1, 340 [1893]) have determined the quantities of Cl obtained by decomposing by heat chlorates of Al, Ba, Cu, Pb, Hg, K, Ag, Na, and Zn; the amount of Cl varied from ·02 p.c. from $KClO_3$ to 14·45 p.c. from $Zn(ClO_3)_2$.

Calcium chlorate. Dry $Ca(ClO_3)_2$ melts between 300°-350°, having previously given off from 3 to 5 p.c. of its weight of O; the rate of evolution of O increases, at 330°, until c. 60 p.c. of the total O is given off, after which the rate decreases. For the quantities of O evolved, of $Ca(ClO_3)_2$ decomposed, and of $CaCl_2$ and $Ca(ClO_4)_2$ formed, *v. abstract* in *C. J.* 62, 1275 [1892].

Potassium chlorate. McLeod (*C. J.* 55, 184 [1889]) concluded from his experiments that when $KClO_3$ is heated with MnO_2 some $KMnO_4$ is formed and again decomposed (*v.* MANGANESE PEROXIDE, vol. iii. p. 183), and that Cl is always given off in this reaction. In 1893 (*B.* 26, 1790) Brunck stated that Cl is not given off when $KClO_3$ and MnO_2 are heated together, but that ozone is produced. McLeod (*C. J.* 65, 202 [1894]) has proved that Cl is produced in the reaction. Fowler a. Grant (*C. J.* 57, 272 [1890]) have studied the influence of various oxides on the decomposition of $KClO_3$ (references are given to older memoirs); they support McLeod's view of the reaction with MnO_2, and think that the oxides of Fe, Co, Cu, and Ni react similarly to MnO_2; acidic oxides, such as V_2O_5, U_3O_8, and WO_3 cause evolution of O accompanied by much Cl, a vanadate, uranate, or tungstate being also formed; powdered glass or sand also assists the reaction, but only when very finely divided (*v.* summary of conclusions, *C. J.* 57, 281-2). According to Thorpe a. Perry (*C. J.* 61, 925 [1892]), the main reaction which occurs when an intimate mixture of $KClO_3$ and iodine is heated is $2KClO_3 + I_2 = 2KIO_3 + Cl_2$, and some of the Cl reacts with unchanged I to form ICl and ICl_3. Basset (*C. J.* 57, 760 [1890]) examined the reactions between $KClO_3$, water, and iodine; he concluded that the main reaction, at 80°, in the presence of a very small quantity of HNO_3Aq, is as shown by the equation $6I_2 + 10KClO_3 + 6H_2O + Aq = 6KHI_2O_6Aq + 4KClAq + 6HClAq$; in evaporating the solution to dryness Cl was given off, and the results of several experiments led to the representation of the change produced by evaporation to dryness as $12KHI_2O_6 + 8KCl + 12HCl = 11KHI_2O_6 + 9KCl + 6H_2O + ICl + ICl.HCl + 4Cl_2$. For determinations of the quantities of oxidising gases (Cl and oxides of Cl) removed by passing air through $KClO_3Aq$ mixed with HClAq, *v.* Pendlebury a. McKillop (*C. S. Proc.* 1893-4. [No. 129] 211).

Strontium chlorate. For experiments on the decomposition of this salt by heat, giving $SrCl_2$, $Sr(ClO_4)_2$, and O, *v.* Potilitzin (*J. R.* 21, 451; *abstract* in *C. J.* 58, 696 [1890]).

CHROMIUM (vol. ii. p. 152). S.H. of pure Cr (0° to 98°) = ·12162 (Jäger a. Krüss, *B.* 22, 2028 [1889]). The at. w. of Cr was re-determined by Rawson in 1889 (*C. J.* 55, 213) by strongly heating $(NH_4)_2Cr_2O_7$, measuring the N given off, and weighing the Cr_2O_3 that remained; also by reducing $(NH_4)_2Cr_2O_7Aq$ to $CrCl_3Aq$ by HClAq and alcohol, ppg. by NH_3Aq, and weighing Cr_2O_3 produced; the mean value thus obtained was 52·06, or 51·98 reduced to 0° and a vacuum (O = 15·96). Meineke in 1891 (*A.* 261, 339; *abstract* in *C. J.* 60, 882 [1891]) re-determined the at. w. of Cr by estimating (1) Ag and Cr, and also O, in Ag_2CrO_4 and in $Ag_2CrO_4.NH_3$, (2) O in $K_2Cr_2O_7$; (3) O and Cr in $(NH_4)_2Cr_2O_7$; the extreme values, from thirty-six experiments, were 52·12 and 51·83; twenty-eight of the experiments gave values between 51·9 and 52. According to Prinz (*C. R.* 116, 392 [1893]), Cr crystallises in minute cubes with pyramidal faces. For the absorption spectra of salts of Cr, *v.* Lapraik (*J. pr.* [2] 47, 305 [1893]).

Preparation.—Glatzel (*B.* 23, 3127 [1890]) says that almost perfectly pure Cr can be obtained by reducing $CrCl_3.KCl$ by Mg powder (for details *v. abstract* in *C. J.* 60, 152 [1891]). Placet (*C. R.* 115, 945 [1892]) prepares Cr by electrolysing a solution of Cr alum, containing an alkali sulphate and H_2SO_4. Moissan (*C. R.* 116, 349 [1893]) says that Cr can be obtained by reducing a mixture of Cr_2O_3 and C in the electric furnace, using a current of 50 volts and 100 ampères, and then breaking up the product, which contains from 8·6 to 12·9 p.c. C, and heating it, mixed with more Cr_2O_3, again in the electric furnace in a carbon crucible.

Chromic acid (vol. ii. p. 154). Miss Field (*C. J.* 61, 405 [1892]) has found that only CrO_3 is obtained by working according to Moissan's directions for preparing H_2CrO_4. Determinations of the increase in the b.p. of water caused by solution of CrO_3 led to the conclusion that an aqueous solution of CrO_3 contains some H_2CrO_4, and probably also $H_2Cr_2O_7$.

Chromic bromide $CrBr_3$ (vol. ii. p. 161). Recoura (*C. R.* 110, 1029, 1193) obtained green $CrBr_3.6H_2O$ by boiling saturated CrO_3Aq with a large excess of HBrAq and concentrating; deliquescent crystals, soluble alcohol, insoluble ether. Unchanged when kept solid, but solution soon becomes blue and then violet, with rise of temperature. By boiling a green solution, then saturating with HBr while cold, filtering, and drying the pp. thus formed on porous plates, crystals of the blue variety, $CrBr_3.6H_2O$, were obtained; very soluble water, insol. alcohol. Heat of solution of blue crystals = 28,700; and of green = 1,860. The blue solid is changed to the green at 100°. (For more details *v. abstract* in *C. J.* 58, 1063 [1890].)

Chromic chloride $CrCl_3$ (vol. ii. p. 161). Marchetti (*G.* 22 [11], 375 [1892]) finds that th molecular lowering of the freezing-point of wate by the violet form of $CrCl_3$ is considerably greate than that caused by the green form.

Chromic fluoride CrF_3 (vol. ii. p. 162) Fabris (*G.* 20, 582 [1890]) obtained $CrF_3.9H_2$ as a green crystalline pp., by adding excess

NH_4FAq gradually to a cold solution of violet $Cr_2(SO_4)_3$. Slightly sol. water; insoluble NH_4FAq or alcohol; heating in air leaves Cr_2O_3. Poulenc (*C. R.* 116, 253 [1893]) obtained CrF_3 in green crystals by heating $CrCl_3$, Cr_2O_3, or $CrF_3.xH_2O$ in HF.

Chromous fluoride. According to Poulenc (*l.c.*), CrF_2 is formed by heating Cr to redness in HF, or by the interaction of $CrCl_2$ and HF at the ordinary temperature. CrF_2, after fusion, is described as a transparent, green, crystalline mass; S.G. 4·11; slightly sol. water, insol. alcohol. Heated in air it gives Cr_2O_3. (For more details *v. abstract* in *C. J.* 64 [11], 281 [1893].)

Chromic oxide Cr_2O_3 (vol. ii. p. 164). Moissan (*C. R.* 115, 1034 [1892]) found that Cr_2O_3 melted to a black mass, dotted with black crystals, in an electric furnace, using a current of 55 volts and 30 ampères.

Chromium trioxide CrO_3 (vol. ii. p. 164). For action of water *v.* CHROMIC ACID, p. 905. Reduced to Cr_2O_3 by NO at the ordinary temperature (Senderens a. Sabatier, *C. R.* 114, 1476 [1892]). For the reaction of CrO_3Aq with O and BaO_2H_2Aq—said to give a pp. approximately $BaCrO_5$—*v.* Péchard, *C. R.* 113, 39 (*abstract* in *C. J.* 60, 1431 [1891]).

Chromium salts (vol. ii. p. 167). According to Recoura (*C. R.* 112, 1439; *abstract* in *C. J.* 60, 1430 [1891]), the green solutions obtained by heating solutions of the normal violet chromic salts contain free acid and a soluble basic salt; in the case of the sulphate this soluble basic salt is said to be $2Cr_2O_3.5SO_3$. For preparation of green soluble normal sulphates *v.* Recoura, *C. R.* 115, 857 (*abstract* in *C. J.* 62, 411 [1892]).

CHROM-AMMONIUM COMPOUNDS (vol. ii. p. 158). Petersen (*Z. P. C.* 10, 580 [1892]) finds, by cryoscopic determinations, that the formulæ usually assigned to the chief salts of this class are probably molecular. For a discussion of the constitution of these salts *v.* Jörgensen (*J. pr.* [2] 42, 206; 45, 274).

CHROMATES; *and derivatives* (vol. ii. p. 154).

Ammonium chromates. According to Jäger a. Krüss (*B.* 22, 2028 [1889]), *normal ammonium chromate* has not hitherto been obtained pure; they prepare the pure salt by adding excess of NH_3Aq S.G. ·9 to CrO_3Aq free from H_2SO_4Aq, warming until the solid that separates dissolves, and placing in a freezing mixture. $(NH_4)_2CrO_4$ crystallises in long, monosymmetric, golden needles, $a:b:c = 1·9603:1:2·4452$; S.G. 1·886 at 11°.

Ammonium trichromate $(NH_4)_2Cr_3O_{10}$ is prepared by J. a. K. (*l.c.*) by dissolving $(NH_4)_2Cr_2O_7$ in hot conc. CrO_3Aq, concentrating, and drying at 100° the red crystals that separate on cooling; S.G. 2·342 at 13°; explodes at 190°, giving off NO_2, and leaving Cr_2O_3.

Ammonium tetrachromate $(NH_4)_2Cr_4O_{13}$ is formed by dissolving the trichromate in warm HNO_3Aq S.G. 1·09, and letting cool slowly; S.G. 2·343 at 10°; melts at 170°, and suddenly decomposes at 175°, giving off NO and leaving Cr_2O_3. J. a. K. (*l.c.*) failed to obtain *hexachromate*; they say that no nitro-chromates are obtained by treating ammonium chromates with HNO_3Aq. (For more details *v. abstract* in *C. J.* 56, 1117 [1889].) Various *double compounds* of $(NH_4)_2Cr_2O_7$ with $HgCl_2$ are described by J. a. K. (*l.c.*).

Ceric dichromate $CeO_2.2CrO_3.2H_2O$. Prepared by passing a current of 2·5 to 3 volts through a slightly acid solution formed by dissolving $Ce_2(CO_3)_3$ in CrO_3Aq; insoluble water; boiling water forms yellow $Ce(CrO_4)_2$ and then $CeO_2.xH_2O$ (Bricout, *C. R.* 118, 145 [1894]).

Lead chromates. For *double compounds* of $PbCrO_4$ with Li_2CrO_4, K_2CrO_4, and Na_2CrO_4, *v.* Lachaud a. Lepierre, *C. R.* 110, 1035 (*abstract* in *C. J.* 58, 1065 [1890]).

Mercury chromates. For *basic mercuric chromates* and a *double compound* of $HgCrO_4$ with NH_2HgCl *v.* Jäger a. Krüss, *B.* 22, 2028 (*abstract* in *C. J.* 56, 1120 [1889]).

Potassium chromates. Jäger a. Krüss (*l.c.*) prepare *potassium trichromate* $K_2Cr_3O_{10}$ by treating $K_2Cr_2O_7$ with HNO_3Aq S.G. 1·19, pouring off from KNO_3 that separates, and crystallising; S.G. 2·648 at 11°. $K_2Cr_3O_{10}$ is quickly decomposed by water to CrO_3Aq and $K_2Cr_2O_7Aq$; melts at 250°. *Potassium tetrachromate* $K_2Cr_4O_{13}$ is prepared by J. a. K. (*l.c.*) by dissolving $K_2Cr_2O_7$ in hot conc. HNO_3Aq S.G. 1·41; S.G. 2·649 at 11°; not deliquescent; decomposed by water; crystallises unchanged from HNO_3Aq S.G. 1·41. Schmidt (*B.* 25, 2917 [1893]) says that no nitrochromate is obtained by the action of HNO_3Aq on $K_2Cr_2O_7$; the substances obtained by Darmstädter (*v.* vol. ii. p. 158) were mixtures of KNO_3 and $K_2Cr_4O_{13}$.

Silver chromates. Pure *silver chromate* Ag_2CrO_4 is prepared by J. a. K. (*l.c.*) by repeatedly boiling $Ag_2Cr_2O_7$ with water as long as anything dissolves; it is a deep-green solid, insol. water.

Sodium perchromate. Häussermann (*J. pr.* [2] 48, 70; *abstract* in *C. J.* 64 [11], 471) describes a salt $Na_6Cr_2O_{15}.28aq$, prepared by adding Na_2O_2 to a thin paste of CrO_3H_3 and water, kept at 10°–20°.

Thallium chromates. For preparation of Tl_2CrO_4 and the *double compound* $Tl_2CrO_4.K_2CrO_4$ *v.* Lachaud a. Lepierre, *Bl.* [3] 6, 232 (*abstract* in *C. J.* 62, 567 [1892]).

Uranium chromates. For *double uranyl chromates* *v.* Formánek, *A.* 257, 102 (*abstract* in *C. J.* 58, 852 [1890]).

IODOCHROMATES (vol. ii. p. 157). A series of salts of the forms $IO_2.O.CrO_2.OM^I$ and $(IO_2.O.CrO_2.O)_2M^{II}$ has been obtained by Berg (*C. R.* 104, 1514 [1887]; 111, 42 [1890]); $M^I = NH_4$, Li, K, Ag, and Na; $M^{II} =$ Co, Cu, Mg, and Ni. Most of the alkali salts were formed by dissolving the alkali iodate in excess of CrO_3Aq and crystallising; the other salts were usually prepared by dissolving the oxide or carbonate of the metal in excess of CrO_3Aq and adding HIO_3Aq. (For details *v. abstracts* in *C. J.* 52, 776 [1887]; 58, 1378 [1890].)

PHOSPHOCHROMATES. By adding conc. $H_3PO_4Aq + CrO_3Aq$ to K_2CO_3Aq, Blondel (*C. R.* 118, 194; *abstract* in *C. J.* 66 [11], 193 [1894]) obtained compounds of the form $mK_2O.P_2O_5.nCrO_3.xaq$, m being 2 and 3, n 4 and 8, and x being 0 or 1.

SULPHOCHROMATES. In 1882 Cross a. Higgin described a compound of Cr_2O_3, SO_3, and H_2O (*C. J.* 41, 113), and also compounds of Cr_2O_3, SO_3, K_2O and H_2O. Recoura (*C. R.* 114, 477

[1892]; 116, 1367; 117, 37, 101 [1893]) has made a more complete examination of these and allied compounds. By evaporating, at 100°, solutions containing violet $Cr_2(SO_4)_3$ and H_2SO_4, in the molecular ratio 1:1, 1:2, and 1:3, R. obtained *chromosulphuric acid* $H_2Cr_2(SO_4)_4$, *chromodisulphuric acid* $H_4Cr_2(SO_4)_5$, and *chromotrisulphuric acid* $H_6Cr_2(SO_4)_6$; by using various sulphates in place of H_2SO_4 he obtained *chromosulphates*, *chromodisulphates*, and *chromotrisulphates*. The acids are green powders, easily sol. water; they gradually decompose in solution; dilute $BaCl_2Aq$ ppts. Ba chromosulphates, but conc. $BaCl_2Aq$ gives $BaSO_4$. R. obtained *chromopyrosulphuric acid* $Cr_2(OH)_2(S_2O_7H)_4$, by evaporating a solution of $Cr_2(SO_4)_3$ and H_2SO_4, in the molecular ratio 1:5, at 100°, and heating the dark-green syrupy liquid so obtained to 110°-115° for some days. The acid forms brittle, transparent, pale-green laminæ. Salts of the form $Cr_2(S_2O_7)_2(OM)_2$ are obtained by adding alkalis to the acid in solution; these salts R. calls *pyrosulphochromites*. By adding conc. HClAq or H_2SO_4 to a solution of chromopyrosulphuric acid, R. obtained a compound $Cr_2(OH)_2(S_2O_7)_2$, *pyrosulphochromic hydroxide*, isomeric with chromosulphuric acid $Cr_2(SO_4)_4H_2$. (For more details *v. abstracts* in *C. J.* 62, 783 [1892]; 64 [11], 470, 528 [1893].)

COBALT (vol. ii. p. 217). Winkler has redetermined at. w. of Co, (1) by dissolving electrolytically deposited Co in HClAq, evaporating to dryness, and determining Cl in the $CoCl_2$ obtained (*Zeit. f. anorg. Chemie*, 4, 10 [1893]); (2) by finding the quantity of Ag deposited from solution of Ag_2SO_4 by electrolytically deposited Co (*l.c.* p. 462). The values obtained were all about 59·6 (Ag = 107·66).

Alleged decomposition of cobalt. Krüss a. Schmidt (*B.* 22, 11, 2026 [1889]) supposed they had separated Ni into two constituents (*v.* vol. iii. p. 500); and they thought that Co also was probably not a homogeneous substance. Remmler, in 1893, obtained a number of specimens of Co_2O_3, by ppg. $CoCl_2Aq$ by KOHAq and Br water, treating the pp. with NH_3Aq, which gradually dissolves it, decanting off the ammoniacal solution at intervals during 9 months, evaporating each and heating in CO_2; the different specimens of Co_2O_3 were heated in H, and the quantity of Co obtained in each case was determined. The values thus obtained for the at. w. of Co varied from 59·53 to 58·3. R. concluded that Co purified by the ordinary methods is not a homogeneous substance. Winkler's determinations of the at. w. (*v. supra*), however, gave very constant values.

Reactions.—Heated in NO to 150°, CoO is formed (Sabatier a. Senderens, *C. R.* 114, 1429 [1892]); finely divided Co burns in NO_2 at the ordinary temperature, giving Co_4O_5; but if the NO_2 is largely diluted with N, a black compound is formed, Co_2NO_2, called by S. a. S. (*C. R.* 115, 236 [1892]) *nitro-cobalt*. This compound reacts rapidly with H_2O, giving off NO, and forming a solution containing $Co(NO_3)_2$ with a very little $Co(NO_2)_2$, Co remaining insoluble, and sometimes also a basic nitrite; when heated in N, oxides of N are given off and then rapid decomposition occurs with formation of Co and oxides of Co; when mixed with combustible substances Co_2NO_2 explodes (S. a. [illegible] *Bl.* [3], [illegible] [1893]). Montemartini (*G.* 22 [1], 250) finds that the gases produced by the interaction of Co and excess of HNO_3Aq (27·5 p.c.) are NH_3, N_2O, and N (*v. abstract* in *C. J.* 62, 1278 [1892]).

Cobalt, chloride of (vol. ii. p. 219). For the solubility of $CoCl_2$ in water, and the changes of colour produced by diluting the solution, with a discussion of the hydrations and dehydrations that accompany these changes, *v.* Étard, *C. R.* 113, 699 (*abstract* in *C. J.* 62, 278 [1892]); Engel, *Bl.* [3] 6, 239 (*abstract* in *C. J.* 62, 569 [1892]); and Potilitzin, *Bl.* [3] 6, 264 (*abstract* in *C. J.*, *l.c.* p. 571). The *double compounds* $CoCl_2.HCl.3aq$, $CoCl_2.LiCl.3aq$, and $CoCl_2.NH_4Cl.6aq$ are described by Chassevant (*A. Ch.* [6] 30, 5 [1893]).

Cobalt, fluoride of (vol. ii. p. 220). Poulenc (*C. R.* 114, 1426; *v. abstract* in *C. J.* 62, 1159 [1892]) prepares CoF_2 by heating $CoCl_2$ with excess of NH_4F for 15 minutes, and repeatedly washing the double fluoride $CoF_2.2NH_4F$ thus obtained with boiling alcohol. By heating CoF_2 to 1200°-1300° in HF, the salt is obtained in small, rose-red prisms; S.G. 4·43. The *double compound* $CoF_2.2KF$ is formed by heating $CoCl_2$ with KHF_2 (*P.*, *l.c.* p. 746; *abstract*, *l.c.* p. 781).

Cobalt, iodide of (vol. ii. p. 220). For solubility in water of CoI_2, and the formation of various hydrates attending solution, *v.* Étard, *C. R.* 113, 699 (*abstract in C. J.* 62, 278 [1892]).

Cobaltous oxide CoO (vol. ii. p. 220). This oxide melts in the electric furnace, and forms rose-coloured crystals (Moissan, *C. R.* 115, 1034 [1892]).

Cobaltous hydroxide CoO_2H_2 (vol. ii. p. 220). A. de Schulten (*C. R.* 109, 266 [1889]) obtained this compound in microscopic, brownish-red, four-sided prisms, S.G. 3·597 at 15°, by heating 10 g. $CoCl_2.6aq$ in 60 c.c. water with 250 g. KOH, in a flask filled with coal-gas, letting stand for 24 hours, and washing away the lighter amorphous products of the reaction.

Cobalto-cobaltic oxides (vol. ii. p. 221). Regarding Co_3O_4 and oxides intermediate between this and Co_2O_3, *v.* Schröder, *C. C.* 1890. [1] 931 (*abstract* in *C. J.* 58, 1213 [1890]). Co_3O_4 heated to c. 1750° loses all its O, and leaves Co (Read, *C. J.* 65, 313 [1894]).

Cobalt, dioxide of. By the reaction of IAq and NaOHAq on $CoSO_4Aq$, filtering, and acidifying with acetic acid, Vortmann (*B.* 24, 2744; *abstract* in *C. J.* 60, 1429 [1891]) obtained a greenish-black pp. nearly agreeing with the formula CoO_2. For compounds of CoO_2 with BaO *v.* Rousseau, *C. R.* 10[illegible], 64 (*abstract* in *C. J.* 56, 1115 [1889]).

Cobalt, salts of (vol. ii. p. 221). Marshall (*C. J.* 59, 760 [1891]) has prepared the salts $Co_2(SO_4)_3.18aq$ and $Co_2(C_2O_4)_3.3(NH_4)_2C_2O_4.6aq$ by electrolysing a solution of $CoSO_4$ in H_2SO_4Aq, and of CoC_2O_4Aq containing $(NH_4)_2C_2O_4$.

COBALTAMMINES (vol. ii. p. 222). By cryoscopic determinations, Petersen (*Z. P. C.* 10, 580 [1892]) concludes that the formulæ generally given to the chief cobaltammines are molecular. For a discussion of the constitution of these compounds, *v.* Jörgensen (*J. pr.* [2] 41, 429, 440 [1890]; 42, 206; 45, 274 [1891-92]). For various *octammines*, *v.* Vortmann a. Blasberg (*B.* 22, 2648), and V. a. Magdeburg (*B.* 22, 2630; *abstracts* in *C. J.* 58, 14 [1890]). V. a. Morgulis (*B.* 22, 2644; *abstract* in *C. J.* 58, 13 [1890]), describe several *mercuricobaltammines*. A number of *croceo-*, *luteo-*, and *xantho- salts*, and also several *flavo- salts* isomeric with the croceo-salts, are described by Jörgensen in *Zeit. f. anorg. Chemie*, 5, 147 (*abstract* in *C. J.* 65 [11], 50 [1894]).

COPPER (vol. ii. p. 251). An elaborate investigation of the at. w. of Cu has been made by Richards, *P. Am. A.* 26, 240 [1891] (*v.* *C. N.* 65, 236, &c.; *abstract* in *C. J.* 64 [11], 12 [1893]). $CuSO_4.5H_2O$ was analysed and synthesised, and CuO was analysed; the final value obtained by R. is 63·604 (O = 16), or 63·44 (O = 15·96). The molecule of Cu in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). For the absorption spectra of solutions of $CuCl_2$, $CuSO_4$, and $Cu(NO_3)_2$, *v.* Evan, *P. M.* [5] 33, 317 (*abstract* in *C. J.* 64 [11], 149 [1893]).

Preparation.—For the preparation by electrolysis of pure copper *v.* Richards (*P. Am. A.* 25, 199, 206 [1890]).

Reactions.—Heated in the electric furnace, using a current of 70 volts and 350 ampères, Cu rapidly volatilises, and the vapour forms CuO in the air (Moissan, *C. R.* 116, 1429 [1893]). According to Neumann (*M.* 13, 40 [1893]), the H occluded in Cu prepared by reducing CuO by H, cannot be wholly expelled by heating in a stream of CO_2; some of the CO_2 is also absorbed by the Cu. N. also says that Cu reduced by vapour of MeOH or EtOH, or by coal gas, retains very small traces of C and H after being heated to 220°. Montemartini (*G.* 22, 384, 397, 426 [1892]) says that the reaction between Cu and HNO_3Aq of less than 30 p.c. produces $Cu(NO_3)_2$ and HNO_2, the HNO_2 then decomposing to HNO_3, NO, and H_2O; with acid more conc. than 30 p.c. HNO_3 some NO_2 is produced with a little N_2O_3, and with 70 p.c. acid only NO_2 is given off; no appreciable quantity of NH_3 is produced with acid from 3 to 27·5 p.c. HNO_3. According to Freer a. Higley (*Am.* 15, 71 [1893]), the only gaseous products of the reaction of Cu with excess of HNO_3Aq S.G. 1·4 (c. 65 p.c. HNO_3) are NO_2 and N_2O_3, c. 90 p.c. NO_2 and 10 p.c. N_2O_3. Cu is superficially oxidised in NO at a dull red heat (Sabatier a. Senderens, *C. R.* 114, 1429 [1892]). Reduced Cu absorbs NO_2 at the ordinary temperature, forming a brownish powder Cu_2NO_2 (S. a. S., *C. R.* 115, 236 [1892]). For the reactions of this *nitro-copper* *v.* S. a. S., *C. R.* 116, 756 (*abstract* in *C. J.* 64 [11], 374 [1893]).

Copper, alloys of (vol. i. p. 253). For a description of alloys of Cu with Cd, Sn, and Zn, prepared by immersing plates of Cd, Sn, or Zn, in solutions of salts of Cu, *v.* Mylius a. Fromm, *B.* 27, 630 (*abstract* in *C. J.* 66 [11], 235 1894]).

Cupric bromide (vol. ii. p. 254). According to Sabatier (*C. R.* 118, 980 [1894]), the green crystals that separate from $CuBr_2Aq$ are $CuBr_2.4aq$. A solution of $CuBr_2$ in conc. HBrAq has an intense purple colour which becomes less marked on dilution, but even with ·0015 mgm. Cu in solution the colour can be detected (S., *l.c.*) The *double salts* $CuBr_2.CsBr$ and $CuBr_2.2CsBr$ are described by Wells a. Walden (*Zeit. f. anorg. Chemie*, 5, 304; *abstract* in *C. J.* 66 [11], 47 [1894]).

Cupric chloride (vol. ii. p. 255). Tzuchanoff (*J. R.* 25, 151; *abstract* in *C. J.* 66 [11], 47 [1894]) finds that the E.C. of dilute blue-coloured $CuCl_2Aq$ increases with increase of concentration to a maximum, after which it decreases while the colour changes to yellowish-brown. For heats of solution and dilution of $CuCl_2.2aq$, *v.* Reicher a. Deventer (*Z. P. C.* 5, 559 [1890]).

Double salts.—$CuCl_2.HCl.3aq$, $CuCl_2.LiCl.xaq$, $CuCl_2.NH_4Cl$, $CuCl_2.2NH_4Cl.2aq$, $CuCl_2.KCl$, and $CuCl_2.2KCl.2aq$ (Chassevant, *A. Ch.* [6] 30, 5 [1893]); $CuCl_2.CsCl$, $CuCl_2.2CsCl.xaq$ ($x = 0$ and 2), and $2CuCl_2.3CsCl$ (Wells a. Dupree, *Zeit. f. anorg. Chemie*, 5, 300 [1893]).

Cuprous chloride (vol. ii. p. 255). Wells (*l.c.*, p. 306) describes the *double salts* $2CuCl.CsCl$, $2CuCl.3CsCl$, and $CuCl.3CsCl.aq$.

Cupric fluoride (vol. ii. p. 256). Pouleno (*C. R.* 116, 1446; *abstract* in *C. J.* 64 [11], 525 [1893]) prepares CuF_2, as a white amorphous powder, by heating NH_4F with $CuF_2.2aq$; by heating in HF at 500° (not above) the CuF_2 becomes crystalline. Crystalline CuF_2 is also obtained by heating CuO, or $CuF_2.2aq$, in HF at 400° (P., *l.c.*). Heated to 300° in air CuO is formed; heating in steam gives CuO and HF; H_2S forms CuS and HF; HCl forms $CuCl_2$. CuF_2 absorbs water from the air, and becomes blue. H. von Helmholt (*Zeit. f. anorg. Chemie*, 3, 115 [1892]) describes the *double salts* $CuF_2.KF$, $CuF_2.RbF$, $CuF_2.AmF.xaq$, and $CuF_2.2AmF.2aq$.

Cuprous fluoride (vol. ii. p. 256). According to Mauro (*Real. Acad. Lincei*, 1892 [1]. 194; *abstract* in *C. J.* 64 [11], 124 [1893]), Cu_2F_2 does not exist, and the substance obtained by Berzelius was almost certainly merely impure copper. Pouleno, however (*C. R.* 116, 1446; *abstract* in *C. J.* 64 [11], 525 [1893]), says that Cu_2F_2 is formed by heating Cu_2Cl_2 to dull redness in HF (the action is not complete until 1100°–1200°); also by heating CuF_2 in HF at c. 600°, raising the temperature to 1100°–1200° towards the end of the reaction. P. describes Cu_2F_2 that has been fused as a ruby-red, transparent solid, with a crystalline fracture; exposed to moist air it changes to $CuF_2.xaq$; it is easily reduced by H at a red heat.

Cuprous iodide (vol. ii. p. 256). Brun (*C. R.* 114, 667; *abstract* in *C. J.* 62, 1157 [1893]) describes *double compounds* with $(NH_4)_2S_2O_3$ and NH_4I, and also with $(NH_4)_2S_2O_3$ and $Cu_2S_2O_3$.

Cuprous oxide (vol. ii. p. 258). Russell (*C. N.* 68, 308 [1893]) prepares Cu_2O by completely reducing $CuSO_4Aq$ mixed with excess of NaCl by SO_2, heating till excess of SO_2 is removed, and then ppg. by Na_2CO_3, added solid to the hot solution. With HFAq, CuF_2Aq and Cu are formed (Pouleno, *C. R.* 116, 1446 [1893]).

Cupric oxide (vol. ii. p. 258). Moissan (*C. R.* 115, 1034 [1892]) says that CuO is entirely decomposed in the electric furnace at c. 2500°, yielding Cu and a crystalline compound of CuO and CaO (the reaction was effected in a block of CaO). By heating CuO to whiteness, in a Fletcher injector-furnace, in an oxidising atmosphere, Bailey a. Hopkins (*C. J.* 57, 269 [1890]) obtained a very hard, yellowish-red solid agreeing with the formula Cu_2O. Richards (*P. Am. A.* 26, 281 [1891]) found that CuO occludes gas, chiefly N; when prepared by heating $Cu(NO_3)_2$ the oxide retained c. ·08 p.c. of its weight of N, which could not be removed by heating. For experiments on the dehydration of $CuO.xH_2O$ *v.* Spring a. Lucion (*Zeit. f. anorg. Chemie*, 2, 195; *abstract* in *C. J.* 64 [11], 210 [1893]). For colloidal, jelly-like $CuO.xH_2O$ *v.* J. van Bemmelen (*Zeit. f. anorg. Chemie*, 5, 466; *abstract* in *C. J.* 66 [11], 191 [1894]).

Copper, oxybromides of (vol. ii. p. 260). Dupont a. Jansen (*Bl.* [3] 9, 193; *abstract* in *C. J.* 64 [11], 463 [1893]) obtained the salt $3CuO.CuBr_2.3aq$ by heating Cu_2Br_2Aq with CuO in a sealed tube at 200°, or, better, by heating neutral dilute Cu_2Br_2Aq at 225°; the compound crystallised in green rhombohedral plates, S.G. 4·39.

Copper, oxychlorides of (vol. ii. p. 260), *v.* Rousseau, *C. R.* 110, 1261 (*abstract* in *C. J.* 58, 1058 [1890]).

Copper, oxysulphides of (vol. ii. p. 260), *v.* Cliche, *Ar. Ph.* 228, 374 (*abstract* in *C. J.* 58, 1211 [1890]).

Copper, phosphides of (vol. ii. p. 260). For descriptions of Cu_5P_2 and Cu_3P, prepared by heating Cu in vapour of P, *v.* Granger, *C. R.* 113, 1401; and for Cu_2P_2, prepared by heating red P with excess of Cu phosphite and water, *v.* G., *C. R.* 117, 231 (*abstracts* in *C. J.* 62, 410 [1892]; and 64 [11], 526 [1893]).

Cupric sulphide. From experiments on the interaction of H_2S and $CuSO_4Aq$, and $CuSO_4Aq$ in presence of acetic acid, Linder a. Picton (*C. J.* 61, 120 [1892]) conclude that a compound $7CuS.H_2S$ is formed, and that then such compounds as $9CuS.H_2S$ and $22CuS.H_2S$ are produced, and finally $(CuS)_n$ is formed.

COPPER-AMMONIUM COMPOUNDS (vol. ii. p. 262). Several derivatives of *cupriammonium bromide* are described by Richards a. Shaw (*P. Am. A.* 28, 247 [1893]).

FERRICYANIDES.

Barium ferricyanide (vol. ii. p. 337); *v.* Rammelsberg, *J. pr.* [2] 39, 455 (*abstract* in *C. J.* 56, 950 [1889]).

Lead ferricyanide (vol. ii. p. 339); *v.* Rammelsberg (*l.c.*).

Potassium ferricyanide (vol. ii. p. 339); *v.* Kassner, *Chem. Zeit.* 13, 1701 (*abstract* in *C. J.* 58, 352 [1890]).

DIDYMIUM (vol. ii. p. 382). For an investigation into the separation of Di and Er, *v.* Krüss, *A.* 265, 1 (*abstract* in *C. J.* 60, 1424 [1891]). For the emission spectra of oxides of neodymium and praseodymium, *v.* Haitinger, *M.* 12, 362 (*abstract* in *C. J.* 62, 2 [1892]). Read (*C. J.* 65, 313 [1894]) says that Di_2O_3 is unchanged at c. 1750°.

ERBIUM (vol. ii. p. 456). For the separation of compounds of Er and Di, *v.* Krüss, *A.* 265, 1 (*abstract* in *C. J.* 60, 1424 [1891]).

FERRITES (vol. ii. p. 547). J. van Bemmelen a. Klobbie (*J. pr.* [2] 46, 497 [1892]) say that $Fe_2O_3.K_2O$ and $Fe_2O_3.Na_2O$ are obtained, in crystals, by continued heating Fe_2O_3 with conc. KOHAq and NaOHAq respectively; these ferrites are decomposed by water, giving $Fe_2O_3.H_2O$.

FLAME (vol. ii. p. 549). Reference should be made to Smithells a. Ingle on 'The Structure and Chemistry of Flames' in *C. J.* 61, 204 [1892], and to Lewes on 'The Luminosity of Coal-gas Flames' in *ibid.* p. 322.

FLUORHYDRIC ACID (vol. ii. p. 558). Berthelot a. Moissan (*C. R.* 109, 209 [1889]) give the thermal data [H,F] = 37,600; [H,F,Aq] = 49,400. For the description of an apparatus for purifying HFAq, *v.* Hamilton (*C. N.* 60, 252 [1889]).

FLUORINE (vol. ii. p. 560). Moissan (*C. R.* 111, 570 [1890]) determined the at. w. (1) by converting Na_2CO_3 into NaF, and this into Na_2SO_4; (2) by converting CaF_2 into $CaSO_4$, and (3) by converting BaF_2 into $BaSO_4$; the mean of the results regarded by M. as the most trustworthy was 19·05. V.D. at the ordinary temperature, 18·3 (Moissan, *C. R.* 109, 861; *v. abstract* in *C. J.* 58, 208 [1890]). A column of F one metre long shows no definite absorption bands (M., *l.c.* p. 937); for the emission spectrum *v.* M. (*l.c.*; *abstract* in *C. J.* 58, 329 [1890]). F does not liquefy at −95° at the ordinary pressure (M., *A. Ch.* [6] 25, 125 [1893]). Gladstone (*P. M.* [5] 31, 1 [1891]) has determined the atomic refraction of F in C_6H_5F to be as follows for the different lines of the solar spectrum, at 22·8°:—

	A	C	D	F	G	H
at. refraction	·63	·63	·53	·48	·44	·35

The values are much smaller than those for Cl, Br, or I, which are 10·0, 15·23, and 25·2 for the line A.

Formation.—According to Brauner (*C. J.* 65, 393 [1894]), F is given off when $3KF.PbF_4.HF$ (*v.* LEAD TETRAFLUORIDE, p. [illegible]) is heated to dull redness.

Reactions.—F combines with the more porous forms of carbon at the ordinary temperature, with incandescence, forming CF_4; the denser forms of C combine with incandescence at from 50° to 100° (Moissan, *C. R.* 110, 276; *abstract* in *C. J.* 58, 557 [1890]). For a discussion of the chemical relations of F, *v.* Moissan, *Bl.* [3] 5, 880 [1891].

GALLIUM (vol. ii. p. 597). Lecoq de Boisbaudran (*C. R.* 114, 815; *abstract* in *C. J.* 62, 930 [1892]) gives measurements of the chief lines in the spark emission spectrum of Ga; the spectrum varies much according to the conditions under which the spark is applied.

GERMANIUM (vol. ii. p. 610). A new mineral from Bolivia, *canfieldite*, Ag_8GeS_6, identical in composition with *argyrodite* from Freiberg, but crystallising in isometric forms (the form of *argyrodite* is monoclinic), is described by Penfield in *Am. S.* [3] 46, 107 (*abstract* in *C. J.* 66 [11], 12 [1894]).

GOLD (vol. ii. p. 647). Mallet (*Pr.* 46, 71; *abstract* in *C. J.* 58, 708 [1890]) has re-determined the at. w. of gold by various methods; the mean value obtained is 196·9, but the value 196·88 M. thinks is more trustworthy. The molecule of gold in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). Gold volatilises considerably in the electric furnace with a current of 70 volts and 360 ampères (Moissan, *C. R.* 116, 1429 [1893]).

Concerning the volatilisation of gold *v.* Rose (*C. J.* 63, 714 [1893]). Neumann (*M.* 13, 40 [1892]) says that gold absorbs from 33 to 48·5 times its volume of O at c. 450°. According to Petersen (*Z. P. C.* 8, 601 [1891]), the heats of formation of $Au_2O_3.3H_2O$ from gold (1) reduced from $AuCl_3$, (2) from $AuHBr_4$, and (3) from AuBr, differ very markedly. From the results of many experiments on the reaction between gold and KCNAq, Maclaurin (*C. J.* 63, 724 [1893]) concludes that O must be present to accomplish solution, and that the equation $4Au + 8KCNAq + O_2 + 2H_2O =$ $4(AuCN.KCN)Aq + 4KOHAq$ (Elsner, *J. pr.* 37, 333 [1846]) expresses the proportion between K and Au in the solution.

Gold, alloys of (vol. ii. p. 648). For an alloy with Cd, AuCd, *v.* Heycock a. Neville (*C. J.* 61, 914 [1892]). For alloys with Cd and Sn, *v.* H. a. N. (*C. J.* 59, 936 [1891]). For alloys with Al and Sn, Cd and Bi, Cd and Pb, and Cd and Tl, *v.* H. a. N. (*C. J.* 65, 65 [1894]). For alloys with Cd and with Zn, prepared by immersing plates of Cd and Zn in solution of a salt of gold, *v.* Mylius a. Fromm (*B.* 27, 630; *abstract* in *C. J.* 66 [11], 235 [1894]).

Gold, bromides of (vol. ii. p. 648). Petersen (*J. pr.* [2] 46, 328) upholds the existence of Au_2Br_4 against the statements of Krüss a. Schmidt (*B.* 20, 2634); in a later paper (*J. pr.* [2] 47, 301) K. a. S. still maintain that $AuBr_3$ is the ultimate product of the reaction of Br with gold (*v. abstracts* in *C. J.* 64 [11], 126, 284). For the *double salts* $AuBr_3.CsBr$ and $AuBr_3.RbBr$, *v.* Wells a. Wheeler (*Am. S.* [3] 44, 157 [1892]).

Gold, chlorides of (vol. ii. p. 649). Petersen (*J. pr.* [2] 46, 328; 48, 88) maintains that Au_2Cl_4 is a definite compound; Krüss a. Schmidt (*J. pr.* [2] 47, 301; *Zeit. f. anorg. Chemie*, 3 421) say this substance is a mixture (*v. abstracts* in *C. J.* 64 [11], 126, 284, 474 [1893]).

Double salts of $AuCl_3$ with CsCl and RbCl are described by Wells a. Wheeler (*l.c.*); for a double salt $AuCl_3.AgCl$, *v.* Hermann (*B.* 27, 596; *abstract* in *C. J.* 66 [11], 234 [1894]).

Gold, sulphides of (vol. ii. p. 651). Concerning the conditions of formation of Au_2S_3, *v.* Antony a. Lucchesi (*G.* 19, 545; *abstract* in *C. J.* 58, 1216 [1890]).

Auric sulphide Au_2S_3. This compound is formed, according to A. a. L. (*G.* 20, 601; 21 [11], 209; *abstracts* in *C. J.* 60, 526; 62, 480 [1892]), by passing H_2S into a solution of $AuCl_3.LiCl$ kept at −10°, extracting LiCl by absolute alcohol, and drying in N at 70°. Au_2S_3 is a black, amorphous solid; decomposed by heat at 200°–205° to Au and S (for other reactions *v. abstracts, l.c.*).

Schneider (*U. S. Geol. Survey Bull.* No. 90, 56 [1892]) obtained aqueous solutions of colloidal Au_2S and Au_2S_3.

HYDRAZOIC ACID (*v.* p. 919, *Addenda*).

HYDROGEN (vol. ii. p. 719). The ratio between the densities of H and O is 1:15·882; the weight in grams of 1 litre of H is ·08991 (Rayleigh, *Pr.* 53, 134 [1893]). For solubility in water, and in alcohol, *v.* Timofeeff (*Z. P. C.* 6, 141); Winkler (*B.* 24, 89); Henrich (*Z. P. C.* 9, 435); (*abstracts* in *C. J.* 60, 15, 384 [1891]; 62, 1043 [1892]). For the line spectrum of H, *v.* Ames (*P. M.* [5] 30, 48 [1890]); and *cf.* Grünwald (*M.* 13, 111; *abstract* in *C. J.* 62, 1381 [1892]).

Wilm (*B.* 25, 217; *abstract* in *C. J.* 62, 563 [1892]) describes a lecture experiment to show the occlusion of H by Pd. Regarding the occlusion of H by other metals *v.* Streintz (*M.* 12, 642; *abstract* in *C. J.* 62, 567 [1892]).

Baker (*C. J.* 65, 611 [1894]) found that a mixture of equal volumes of *dry* H and *dry* Cl did not explode in bright sunlight, and that more than a quarter of the mixed gases remained uncombined after exposure for two days to diffused light and two days to bright sunshine.

Reactions.—Neumann (*Z. P. C.* 14, 193 [1894]) has examined the reducing action of H occluded by Pt on solutions of salts of Al, Sb, As, Bi, Cd, Cu, Co, Au, Fe, Pb, Mg, Mn, Hg, Ni, Pd, Ag, Sn, Tl, and Zn. Regarding the rate of combination of H and O, *v.* WATER (p. 860). Regarding the explosion of mixtures of H with O and Cl, *v.* CHLORINE (*Addenda*, pp. 904, 905).

Hydrogen dioxide (vol. ii. p. 722). Schöne (*B.* 26, 3011; 27, 1233 [1893-4]) affirms the occurrence of H_2O_2 in the atmosphere against the contention of Ilosva (*B.* 27, 920).

Formation.—Regarding the formation from ether *v.* Dunstan a. Dymond (*C. J.* 57, 574, 988 [1890]). H_2O_2Aq is formed by the action of light on $H_2C_2O_4Aq$, excess of O being present (Richardson, *C. J.* 65, 450 [1894]). Richardson (*C. J.* 63, 1110 [1893]) has examined the formation of H_2O_2 in urine exposed to sunlight.

Preparation.—By making commercial 3 p.c. H_2O_2Aq distinctly alkaline by Na_2CO_3, filtering, shaking with 10–12 vols. of ether, separating the ethereal solution, evaporating this to ·01–·0025 of its original volume on a water-bath, and removing the rest of the ether by standing in a bell-jar over solid paraffin, Shiloff (*J. R.* 25, 293; *abstract* in *C. J.* 66 [11], 186 [1894]) obtained a thick, transparent, slightly acid liquid, S.G. 1·2475, containing 79·6 g. H_2O_2 in 100 c.c. For preparation of conc. H_2O_2Aq *v.* Talbot a. Moody (*abstract* in *C. J.* 64 [11], 369 [1893]).

Molecular weight. Tammann in 1889 (*Z. P. C.* 4, 441) by cryoscopic measurements determined mol. formula to be H_4O_4; but T.'s results were called in question by Carrara in 1893 (*G.* 22 [1], 341), who found mol. w. 33·92 (H_2O_2) from cryoscopic measurements, and this result was confirmed by Orndorff a. White (*Am.* 15, 347 [1893]), and also by Tammann himself (*Z. P. C.* 12, 431 [1893]).

Reactions.—Regarding the reaction between H_2O_2Aq and $KMnO_4Aq$, *v.* Engel (*Bl.* [3] 6, 17; *abstract* in *C. J.* 62, 277 [1892]).

Hydrogen sulphide (vol. ii. p. 725). Henrich (*Z. P. C.* 9, 435 [1892]) gives the absorption coefficient of H_2S by water as $4·4015 - ·089117t + ·00061954t^2$. Hughes (*P. M.* [5] 33, 471 [1892]) says that H_2S dried by $CaCl_2$ and P_2O_5 does not redden dry litmus paper, and does not react with BaO or Fe_2O_3, nor with salts of Sb, As, Bi, Cd, Co, Cu, Pb, Hg, Ag, or Sn. According to Pedler (*C. J.* 57, 625 [1890]), the equation $2H_2S + 3O_2 = 2SO_2 + 2H_2O$ correctly represents the explosion of H_2S and air or O.

HYDROXYLAMINE (vol. ii. p. 734). NH_2OH has been isolated, as a solid, by

(R. T. C. 10, 100; 11, 18; abstracts in C. J. 62, 402, 1891 [1892]). $NH_2OH.HCl$ dissolved in MeOH is treated with CH_3ONa solution, and most of the MeOH is distilled off at 100 mm. pressure; the residue is distilled in small portions at 40 mm. pressure (for details v. C. J., l.c.). For the preparation from $2NH_2OH.ZnCl_2$ v. Crismer, *Bl.* [3] 6, 793 (*abstract* in C. J. 62, 771 [1892]). For details of suitable apparatus for the fractionation of NH_2OH *in vacuo*, v. Brühl (*B.* 26, 2508 [1893]; *cf.* L. de B., *B.* 27, 967; and reply by B., *ibid.* 1347 [1894]). For thermal data of NH_2OH, v. Berthelot a. André (*C. R.* 110, 830; *abstract* in *C. J.* 58, 934 [1890]). Hydroxylamine is a white inodorous solid, melting at c. 33°, and remaining superfused at 0°; boils at 58° under 22 mm. pressure; decomposes at 90°-100°, and detonates at a higher temperature. S.G. 1·35; S.G. when liquid, 1·23. A drop heated in a test tube explodes very violently (v. Brühl, *l.c.*). B., *l.c.*, discusses the molecular refraction of NH_2OH. NH_2OH is fairly stable up to 15°, then gradual decomposition occurs, giving NH_3, HNO_2, and $H_2N_2O_2$, which react with unchanged NH_2OH producing $_2$O and N (L. de B., *B.* 27, 967; *abstract* in C. *J.* 66 [11], 278 [1894]). For a full account of the reactions of NH_2OH v. Lobry de Bruyn (*l.c.*; *abstract* in *C. J.* 62, 1391 [1892]). $NH_2OH.HCl$ in water and $NaNO_2Aq$ react to form $Na_2N_2O_2Aq$ (*v.* Tanatar, *J. R.* 25, 342; *abstract* in *C. J.* 66 [11], 136 [1894]; *cf.* Vislicenus, *B.* 26, 771; *abstract* in *C. J.* 64, 618 [1892]). For the reactions of $2NH_2OH.H_2SO_4$ with NaOHAq v. Kolotoff (*J. R.* 25, 295; *abstract* in *C. J.* 66 [11], 187 [1894]). For compounds of NH_2OH with metallic salts, *v.* Crismer (*Bl.* [3] 8, 114); Goldschmidt a. Syngros (*Zeit. f. anorg. Chemie*, 5, 129); and Feldt (*B.* 27, 401) (*abstracts* in *C. J.* 58, 558 [1890]; 66 [11], 45, 187 [1894]). Kolotoff discusses the constitution of NH_2OH in *J. R.* 23, 3 (*abstract* in *C. J.* 64 [11], 114 [1893]). Kjellin (*B.* 26, 2377) describes NHEt.OH and NHMe.OH (*abstract* in *C. J.* 66 [11], 9 [1894]).

INDIUM (vol. iii. p. 1). The molecule of indium in dilute solution in tin is perhaps diatomic (*v.* Heycock a. Neville, *C. J.* 57, 376 [1890]). Linder a. Picton (*C. J.* 61, 134 [1892]) failed to isolate *indium hydrosulphide*, but they think that it is formed by passing H_2S into water with $In_2O_3.xH_2O$ in suspension; the continued passage of H_2S produces In_2S_3. Read (*C. J.* 65, 313 [1894]) found that *indium sesquioxide*, In_2O_3, is unchanged at c. 1750°.

IODHYDRIC ACID (vol. iii. p. 11). For the Mol. R. of HIAq from 20·77 to 67·02 p.c., *v.* Perkin (*C. J.* 55, 708 [1889]). For a research on the dissociation of HI, *v.* Bodenstein (*Z. P. C.* 13, 56 [1894]; *abstracts* in *C. J.* 64 [11], 369; 66 [11], 12 [1893-4]). Pickering (*B.* 26, 2307) has isolated three *hydrates* of HI: $HI.2H_2O$, melting at c. −43°; $HI.3H_2O$, melting at c. −48°; and $HI.4H_2O$, melting at c. −36·5°.

IODINE (vol. iii. p. 14). The mol. w. of iodine dissolved in Et_2O or CS_2 was found by Beckmann (*Z. P. C.* 5, 76 [1890]) to be 254, from determinations of the boiling-points; whose results were confirmed by Sakurai (*C. J.* 61, 994 [1892]). By determining the lowering of the f.p. of naphthalene by solution therein of I, Hertz (*Z. P. C.* 6, 358 [1890]) found the value 254 for the mol. w. of iodine.

According to Meineke (*Chem. Zeitung*, 16, 1219, 1230), very pure I is prepared by covering ordinary I with a solution of $CaCl_2$ S.G. 1·35, mixed with a little conc. KIAq and a few drops of HClAq, heating until the I fuses, letting cool, washing the I, drying and subliming it twice, the first time with addition of a little BaO.

For the reactions of I with $KClO_3$, and with $KClO_3$ and water, *v.* POTASSIUM CHLORATE (*Addenda*, p. 905).

Iodine monochloride (vol. iii. p. 17). For thermal data bearing on the two forms of ICl, *v.* Stortenbeker (*Z. P. C.* 10, 183; *abstract* in *C. J.* 62, 1387 [1892]). Tanatar (*J. R.* 25, 97; *abstract* in *C. J.* 64 [11], 514) gives details of the methods for preparing the two forms of ICl.

Iodates (vol. iii. p. 21). For *iodates of cæsium* and *rubidium*, *v.* Wheeler, *Am. S.* [3] 44, 123 (*abstract* in *C. J.* 64 [11], 68 [1894]). Pure *potassium iodate* is prepared, according to Gröger (*Zeit. angew. Chemie*, 1891. 13), by heating to 100° for 20-30 minutes 20 g. KI in as little water as possible mixed with 40 g. pure $KMnO_4$ in 1,000 c.c. water, reducing excess of $KMnO_4$ by cautious addition of alcohol, filtering, adding acetic acid till acid, evaporating to c. 50 c.c., washing the crystals of KIO_3 with conc. alcohol, and drying. By heating KIO_3 till it fuses, O and some I are given off, and KI finally remains; no other oxy- compounds are formed (Cook, *C. J.* 65, 802 [1894]).

IRIDIUM (vol. iii. p. 46). From analyses of the salts $ICl_3.3KCl.aq$ and $ICl_3.3NH_4Cl.aq$, Joly deduced the value 192·75 for the at. w. of Ir (*C. R.* 110, 1131 [1890]). According to Prinz (*C. R.* 116, 392 [1893]), Ir crystallises in regular octahedra and in forms derived therefrom. Mylius a. Foerster (*B.* 25, 665 [1892]) stated that Ir is slightly volatilised when heated in a current of CO and Cl to c. 238°; Antony, however (*G.* 23 [11], 547 [1893]), asserts that no trace of any volatile compound of Ir is formed under these conditions.

Irid-ammonium salts (vol. iii. p. 47). Palmaer (*B.* 22, 15; 23, 3810 [1889-90]) describes a number of *irido-ammonium compounds*. He calls them *iridiumpentammine salts*, and formulates them as $Ir(NH_3)_5X^I_3$: compounds are described where $X_3 = Cl_3$, $ClBr_2$, ClI_2, $ClSO_4$, $Cl(NO_3)$, $Cl(NO_2)_2$, ClC_2O_4, $ClPtCl_6$; also where $X_3 = Br_3$, $BrSO_4$, and $Br(NO_3)_2$. One-third of the Cl in the salt when $X_3 = Cl_3$ is not removed by the action of cold H_2SO_4Aq or cold $AgNO_3Aq$; the reactions of the salts are similar to those of the purpureo-cobaltammines (*v.* vol. ii. p. 227) (*abstracts* in *C. J.* 56, 252 [1889]; 60, 402 [1891]). In *B.* 21, 2090 (*v. abstract* in *C. J.* 60, 11 [1891]) P. describes compounds analogous with the roseo-cobaltic salts $Co_2(NH_3)_{10}(H_2O)_2X^{II}_2.xAq$; as the Ir salts are almost colourless, P. thinks the prefix *roseo-* is unsuitable; he calls them *iridium aquopentammines*, and formulates them as $Ir(NH_3)_5(H_2O)X^I_3$. Salts are described in which $X_3 = Br_3$, Cl_3, and $(NO_3)_3$. The *chloride* $Ir(NH_3)_5(H_2O)Cl_3$ is formed by boiling, for five hours, 5 g. $Ir(NH_3)_5Cl_3$ with 1½ times the calculated weight of KOH in 50 c.c. water, filtering, partially freezing the filtrate, adding 30 c.c. fuming HClAq, washing the pp. thus formed with 22 p.c. cold HClAq and then with alcohol, dissolving in water, and again ppg. by conc. HClAq (for details *v. abstract* in *C. J.* 60, 1166 [1891]).

Iridium tribromide (vol. iii. p. 48). Compounds of this bromide with PBr_3 are described by Geisenheimer (*C. R.* 111, 40; *abstract* in *C. J.* 58, 1383 [1890]). By heating $IrO_2.xH_2O$ with $IrBr_3$ and PBr_3, red needles of $IrBr_3.3PBr_3$ are formed; by heating this with PBr_3, black crystals of $IrBr_3.2PBr_3$ are produced.

Iridium tetrabromide (vol. iii. p. 48). Geisenheimer (*l.c.*) describes the compound $IrBr_4.2PCl_3$, obtained by heating $IrBr_3.3PBr_3$ with PCl_3.

Iridium trichloride (vol. iii. p. 48). The following compounds with PCl_3 are described by Geisenheimer (*C. R.* 110, 1004; *abstract* in *C. J.* 58, 1068 [1890]). $IrCl_3.3PCl_3$; $IrCl_3.2PCl_3$; $IrCl_3.PCl_5.2PCl_3$; $IrCl_3.PCl_3.PCl_5$. Various compounds of $IrCl_3$ with H_3PO_3 and H_3PO_4, and salts of these, are also described. G. (*C. R.* 110, 1336; *abstract* in *C. J.* 58, 1069 [1890]) also describes the complex compounds $2IrP_2Cl_{13}.5AsCl_3$ and $IrCl_3.2PCl_3.2AsCl_3$. For the salts $IrCl_3.3KCl.$ aq and $IrCl_3.3NH_4Cl.$ aq, *v.* Joly (*C. R.* 110, 1131; *abstract* in *C. J.* 58, 1067 [1890]). For a description of $IrCl_3.3LiCl.xaq$, *v.* Antony (*G.* 23 [1], 190; *abstract* in *C. J.* 64 [11], 380 [1893]). According to A. (*G.* 23 [1], 184; *abstract* in *C. J.* 64 [11], 379 [1890]), the passage of H_2S through a 2 p.c. solution of $IrCl_3.3KCl$ produces pps. which are mixtures of Ir_2S_3 and IrS_2.

Iridium dioxide (vol. iii. p. 50). For methods of preparing IrO_2, *v.* Geisenheimer (*C. R.* 110, 855; *abstract* in *C. J.* 58, 948 [1890]).

Iridium disulphide (vol. iii. p. 50). IrS_2 is obtained by passing H_2S over $IrCl_3.3LiCl$ at 4° to 7°, washing with absolute alcohol, and drying at 90° to 100° in a current of CO_2 (Antony, *G.* 23 [1], 190; *abstract* in *C. J.* 64 [11], 380 [1893]).

IRON (vol. iii. p. 51). Lockyer (*Pr.* 54, 359 [1893]) gives the emission spectrum obtained by using very fine electrolytically deposited iron as the poles of an electric lamp.

Properties and Reactions.—Iron volatilises in the electric furnace, using a current of 850 ampères and 50 volts (Moissan, *C. R.* 116, 1429 [1893]). Iron is superficially oxidised by heating to dull redness in NO (Sabatier a. Senderens, *C. R.* 114, 1429 [1892]); heated in NO_2 to c. 350°, reduced iron is oxidised with incandescence to Fe_2O_3 (S. a. S., *C. R.* 115, 236 [1892]; *cf. abstract* in *C. J.* 66 [11], 95 [1894]). Montemartini (*G.* 22 [1], 350) says that NH_3, N_2O, and N are formed by the solution of iron in excess of 27·5 p.c. HNO_3Aq (for quantities, *v. abstract* in *C. J.* 62, 1278 [1892]). For quantities of iron dissolved by HNO_3Aq of different concentrations, *v.* Gautier a. Charpy (*C. R.* 112, 1451; *abstract* in *C. J.* 60, 1426 [1891]).

Passivity of iron. Concerning the passivities of steel and wrought iron to HNO_3Aq, *v.* Andrews (*Pr.* 48, 116; 49, 481; *abstracts* in *C. J.* 60, 250, and 64 [11], 16 [1891 and 1893]).

Iron, bromochloride of. The compound $FeBrCl_2$ was obtained by Lenormand (*C. R.* 116, 820; *abstract* in *C. J.* 64 [11], 377) by heating $FeCl_2$ with excess of Br in a sealed tube at c. 100°. The compound is opaque in thin sections, and green by reflected light; very deliquescent; crystallises probably in hexagonal plates; easily sol. alcohol and ether, CS_2, &c.; can be sublimed by heating in a tube containing a little Br.

Iron carbide. Arnold a. Read (*C. J.* 65, 788 [1894]) confirm the existence of Fe_3C in steel (*v.* Abel, *Proc. Inst. Mechan. Engineers*, 1885. 80; also Müller, *Stahl und Eisen*, No. 3); A. a. R. say that two forms of Fe_3C are found in steel.

Iron carbonyls. In 1891 Mond a. Quincke (*C. J.* 59, 604) obtained a compound of Fe with CO; further investigation of the reaction by Mond a. Langer (*C. J.* 59, 1090 [1891]) led to the isolation of two compounds.

Ferropentacarbonyl $Fe(CO)_5$. Mol. w. 195·55. V.D. at 142° = 93·2, S.G. $\frac{18°}{18°} = 1·4664$; distils completely, without decomposition, at 102·8° under 749 mm. pressure; solidifies at −21°.

Preparation.—FeC_2O_4, ppd. by adding a slight excess of $K_2C_2O_4Aq$ to hot $FeSO_4Aq$, is well washed, and dried at 120°; it is then heated in a slow stream of H, temperature being raised until the substance in the tube is black, and then kept constant until gas ceases to come off, when the current of H is stopped; the product is allowed to cool in H, placed in water without coming into the air, and treated with successive quantities of boiling water until sulphate is removed; it is then quickly dried on plates of gypsum, placed in the combustion tube, heated to c. 300° in H till quite dry, and allowed to cool in H. The tube is then connected with a gas-holder containing CO, and the H is completely displaced by CO; one end of the tube is then sealed, and the open end is kept in connection with the supply of CO. After 24 hours the tube is heated to c. 120°, while a slow current of CO is passed through it, and the issuing gases are passed through a tube kept at −20°. When iron carbonyl ceases to come over, the tube is let cool, and is then again put in connection with the CO supply. These processes are repeated many times; the daily yield of the carbonyl is not more than c. 1 g. from 100 g. iron.

Properties.—A pale-yellow, somewhat viscous liquid; unchanged in the dark, but in sunlight gives solid $Fe_2(CO)_7$ (*v. infra*); slowly decomposed on exposure to air, giving chiefly $Fe_2O_3.xH_2O$; completely decomposed at 180° to Fe and CO; soluble in EtOH, Et_2O, C_6H_6, mineral oils, &c. (For S.G., V.D., &c., *v. supra.*) $Fe(CO)_5$ is not acted on by dilute H_2SO_4Aq, HClAq, or HNO_3Aq at the ordinary temperature; but is rapidly decomposed—to $Fe(NO_3)_3Aq$, $FeCl_3Aq$, or $FeBr_3Aq$—by conc. HNO_3Aq, ClAq, and BrAq.

Diferroheptacarbonyl $Fe_2(CO)_7$. Obtained by exposing $Fe(CO)_5$ in a sealed tube to sunlight for some hours, collecting the solid that forms, washing with ether, and drying over H_2SO_4 for a short time. Yellow, lustrous flakes; gradually decomposed by exposure to air, turning brown. Not acted on by H_2SO_4Aq or HClAq at the ordinary temperature; decomposed by HNO_3Aq, Cl or Br.

Iron carbonyls seem to be present in waters; also sometimes in compressed coal-gas (v. Roscoe a. Scudder, *C. J. Proc.* 1891. No. 101).

Ferrous chloride (vol. iii. p. 53). Chassevant (*A. Ch.* [6] 30, 5 [1893]) describes the *double salts* $FeCl_2.2AmCl$, $FeCl_2.LiCl.3aq$, and $FeCl_2.2KCl$.

Ferric chloride (vol. iii. p. 54). By determining the rise of b.p. of alcohol and ether when $FeCl_3$ is dissolved in these solvents, Müller (*C. R.* 118, 644; *abstract* in *C. J.* 66 [11], 282 [1894]) finds that the molecular formula of the chloride in these solutions is $FeCl_3$. $FeCl_3Aq$ reacts with many metallic sulphides, when heated therewith in sealed tubes; $FeCl_2Aq$, S, and a chloride of the metal of the sulphide are generally formed (Cammerer, *C. C.* 1891 [11]. 370; *abstract* in *C. J.* 62, 18 [1892]). Seubert a. Dorrer (*Zeit. f. anorg. Chemie*, 5, 339, 411; *v. abstracts* in *C. J.* 66 [11], 140, 190 [1894]) have made a full investigation of the interaction of $FeCl_3Aq$ and KIAq; their results are in keeping with the hypothesis that the direct reaction $FeCl_3Aq + KIAq = FeCl_2Aq + KClAq + IAq$ is counterbalanced by the reverse reaction $FeCl_2Aq + KClAq + IAq = FeCl_3Aq + KIAq$. S. a. D. think that the first stage of the reaction is to produce an iodochloride; thus $FeCl_3Aq + KIAq = FeICl_2Aq + KClAq$; that this then decomposes, more or less completely (according to conditions of concentration, time, temperature, and mass), into $FeCl_2Aq$ and IAq; and that $FeICl_2Aq$, and probably $FeCl_3Aq$, are re-formed until equilibrium is established. S. a. D. do not agree with the explanation of the mechanism of the reaction given by Carnegie (*v.* vol. iii. p. 55). Roozeboom (*Z. P. C.* 10, 477 [1892]) has investigated the conditions of equilibrium in aqueous solution of the *hydrates* of $FeCl_3$; he has isolated hydrates $2FeCl_3.xH_2O$ where $x = 4, 5, 7$, and 12. (For details, *v. abstract* in *C. J.* 64 [11], 119 [1893]). For a study of the interaction of $FeCl_3Aq$ and oxalic acid, *v.* Lemoine, *C. R.* 116, 981 (*abstract* in *C. J.* 64 [11], 405 [1893]). A compound of $FeCl_3$ with *nitrosyl chloride*, $FeCl_3.NOCl$, was obtained by Sudborough (*C. J.* 59, 660 [1891]), by immersing iron in liquid NOCl, and letting the liquid stand over H_2SO_4; the compound forms small golden-brown, deliquescent crystals (*cf.* vol. iii. p. 56; *Combinations*, No. 7).

Ferrous fluoride (vol. iii. p. 56). FeF_2 was obtained by Poulenc (*C. R.* 115, 941; *abstract* in *C. J.* 64 [11], 122 [1893]) by passing air-free HF over red-hot iron or dry $FeCl_2$; small, white, rhombic prisms; S.G. 4·09; decomposed by heating with H_2SO_4, Na_2CO_3, steam, air, HCl, or H.

Ferric fluoride (vol. iii. p. 56). Poulenc (*l.c.*) obtained FeF_3, in small, very refractive, greenish crystals, S.G. 3·87, by passing HF over red-hot iron, Fe_2O_3, $FeF_3.xaq$, or $FeCl_3$; also by dropping $FeF_3.xaq$ into fused AmCl and heating in a current of an inert gas. FeF_3 does not fuse at 1000°; but is decomposed by heating in air, also by fusion with Na_2CO_3, by heating in steam, or with HCl or H_2SO_4. According to Speransky (*J. R.* 24, 304; *abstract* in *C. J.* 64 [11], 314 [1893]), FeF_3Aq shows a very small electrical conductivity; there is, therefore, no appreciable electrolytic dissociation; as the solution scarcely effects any inversion of cane sugar, S. concludes that there is practically no hydrolytic dissociation. Cryoscopic determinations showed that the molecules in a dilute aqueous solution are chiefly FeF_3, but indicated the existence of Fe_2F_6 in more conc. solutions.

Iron, nitrides of (vol. iii. p. 59). Fowler (*C. N.* 68, 152 [1893]) obtained Fe_2N by heating reduced iron in a rapid stream of NH_3. (For details *v. abstract* in *C. J.* 66 [11], 50 [1894].)

Ferric oxide (vol. iii. p. 61; also p. 57 for *hydrates*). At c. 1750° Fe_2O_3 is completely changed to Fe_3O_4 (Read, *C. J.* 65, 313 [1894]); in the electric furnace Fe_3O_4 is formed, partly melted and partly crystallised (Moissan, *C. R.* 115, 1034 [1892]). According to J. van Bemmelen a. Klobbie (*J. pr.* [2] 46, 497 [1893]), crystallised $Fe_2O_3.H_2O$ is obtained by treating with water the hexagonal crystals of $Fe_2O_3.Na_2O$ formed by heating Fe_2O_3 for some time with conc. NaOHAq; the crystalline $Fe_2O_3.H_2O$ is not hygroscopic; H_2O is given off below 100°.

Iron, oxychlorides of (vol. iii. p. 62). Rousseau (*C. R.* 110, 1032; 113, 643; 116, 392; *abstracts* in *C. J.* 58, 1083 [1890]; 62, 119 [1892]; 64 [11] 280 [1893]) describes compounds $xFeCl_3.yFe_2O_3$, some crystalline and some amorphous, formed by heating $FeCl_3Aq$ at different temperatures, and also by the interaction of $FeCl_3$ and steam.

LANTHANUM (vol. iii. p. 116). Bettendorff (*A.* 256, 159 [1890]) obtained the value 138·28 for the at. w.; and Brauner (*B.* 24, 1328 [1891]) the value 138·21 (O = 16).

Winkler (*B.* 24, 873 [1891]) obtained results, by heating La_2O_3 with Mg in H, which pointed to the existence of a *hydride* of La (*cf.* Brauner, *l.c.*).

LEAD (vol. iii. p. 122). The molecule in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). The m.p. of lead was found by Griffiths a. Calendar (using a Pt thermometer) to be 327·69° (*C. N.* 63, 1 [1891]). Lehmann (*Z. K.* 17, 274 [1890]) says that lead separated electrolytically, by a weak current, crystallises in leaflets that are probably monosymmetric, but that the crystals are regular octahedra when separated by a strong current. Veley (*S. C. I.* 10, 206; summary of conclusions in *C. J.* 62, 410 [1892]) has examined the interaction of lead and nitric acid: an acid of intermediate concentration acts most rapidly; when HNO_2 is present the action increases. Montemartini (*G.* 22, 384, 397, 426 [1892]) found that a little NH_3 was produced, especially with dilute HNO_3Aq. Lead rapidly oxidises to PbO when heated in NO; oxidation occurs at c. 200° in NO_2, with formation of a basic nitrate (Sabatier a. Senderens, *C. R.* 114, 1429; 115, 236 [1892]).

Lead, bromide of (vol. iii. p. 125). Several *double compounds* of $PbBr_2$ with alkali bromides have been described. For $PbBr_2.2AmBr.aq$ and $2PbBr_2.AmBr$, *v.* Wells a. Johnston, *Am. S.* [3] 46, 25 (*abstract* in *C. J.* 64 [11], 523 [1893]); for $PbBr_2.KBr.xaq$ and $PbBr_2.2KBr.aq$, *v.* Herty, *Am.* 15, 357 (*abstract* in *C. J.* 66 [11], 465 [1894]); for $2PbBr_2.RbBr$ and $2(PbBr_2.2RbBr).aq$ *v.* Wells, *Am. S.* [3] 46, 34 (*abstract* in *C. J.* 66 [11], 324 [1893]); and for $K_2Pb_2Br_6.4aq$ and $K_2Pb_2(BrI)_3.4aq$, *v.* Wells, *l.c.* p. 190 (*abstract*, *l.c.* p. 524).

Lead, chlorides of (vol. iii. p. 125). The statement, on p. 125 (vol. iii.), that only one chloride has been isolated is no longer true; $PbCl_4$ was prepared by Friedrich in 1893.

Lead tetrachloride (vol. iii. p. 126). $PbCl_4$ has been obtained by Friedrich (*B.* 26, 1434; *abstract* in *C. J.* 64 [11], 415 [1893]; *cf. M.* 14, 505; *abstract* in *C. J.* 66 [11], 16 [1894]), by passing Cl into HClAq containing $PbCl_2$ in suspension, adding NH_4Cl to the solution thus obtained, separating and drying the compound $PbCl_4.2NH_4Cl$ thus formed, adding it to conc. cooled H_2SO_4, allowing the oily drops that formed to collect at the bottom of the vessel, and shaking these drops repeatedly (and quickly) with conc. H_2SO_4. $PbCl_4$ is a transparent, yellow, very refractive liquid, fuming in moist air with formation of $PbCl_2$ and Cl; it is unchanged in contact with cold conc. H_2SO_4, but when heated with the acid it decomposes explosively to $PbCl_2$ and Cl; when heated with conc. H_2SO_4 in a current of Cl, some $PbCl_4$ passes over, but at c. 105° explosion occurs. $PbCl_4$ has S.G. 3·18 at 0°; at c. −15° it solidifies to a yellowish, crystalline mass. A *hydrate* is formed with a little water; but addition of more water produces HClAq and PbO_2. By adding $PbCl_4$ to a little cooled conc. HClAq, a crystalline compound, probably $PbCl_4.2HCl$, is formed.

Several *double salts* of $PbCl_4$ with alkali chlorides have been isolated. Classen a. Zahorski (*Zeit. f. anorg. Chemie*, 4, 100) give the formula $2PbCl_4.5AmCl$ to the salt formed by digesting $PbCl_2$ with liquid Cl and fuming HClAq, and adding AmCl; but Friedrich (*l.c.*) says the compound is $PbCl_4.2NH_4Cl$. For compounds $PbCl_4.2MCl$, when $M = NH_4$, Cs, K, and Rb, *v.* Wells (*Am. S.* [3] 46, 180; *abstract* in *C. J.* 64 [11], 523 [1893]); C. a. Z. (*l.c.*) describe compounds of $PbCl_4$ with the hydrochlorides of pyridine and quinoline (*abstract* in *C. J.* 64 [11], 462 [1893]).

Lead dichloride (vol. iii. p. 125). Several *double compounds* with alkali chlorides are described by Randall (*Am.* 15, 494 [1893]); Wells a. Johnston (*Am. S.* [3] 46, 25 [1893]); and Wells (*l.c.* p. 34). The compounds are of the forms $PbCl_2.2MCl$, $PbCl_2.3MCl.xaq$, and $2PbCl_2.MCl$ (*v. abstracts* in *C. J.* 64 [11], 523, 524 [1893]).

Lead, fluorides of (vol. iii. p. 127). Brauner (*C. J.* 65, 393 [1894]) has prepared the compound $PbF_4.3KF.HF$ in various ways; the simplest process being to dissolve $Pb(C_2H_3O_2)_4$ (*v.* RED OXIDE OF LEAD, *Addenda, infra*) in conc. HFAq and add KF. By acting on this salt with conc. H_2SO_4, B. obtained evidence of the formation of *lead tetrafluoride*, PbF_4, but he did not succeed in isolating the compound.

Lead, iodide of (vol. iii. p. 127). Several *double compounds* of PbI_2 with alkali iodides have been isolated by Wells, W. a. Johnston, and Herty (*v. References* under LEAD BROMIDE, p. 914). For the compound $PbI_2.2MgI_2.16aq$, *v.* Otto a. Drewes (*Ar. Ph.* 229, 179; *abstract* in *C. J.* 64 [11], 984 [1893]).

Lead iodobromides and iodochlorides (vol. iii. p. 128). Miss Field (*C. J.* 63, 540 [1893]) has described the compounds $2PbBr_2.PbI_2$, $2PbCl_2.PbI_2$, and $5PbCl_2.PbI_2$.

Lead protoxide (vol. iii. p. 128). PbO is unchanged at c. 1750° (Read, *C. J.* 65, 318 [1894]). The hydrate $2PbO.H_2O$ (vol. iii. p. 12 is obtained in large crystals by allowing a solution of PbO in KOHAq to cool in the air; CO is absorbed, and the hydrate is deposited i colourless, tetragonal crystals, *a:b:c* = 1:·82 (Luedeking, *Am.* 13, 120 [1891]).

Red oxide of lead (vol. iii. p. 130). Hutchinson a. Pollard (*C. J.* 63, 1136 [1893]) have examined the reaction of Pb_3O_4 with glacial acetic acid, and have isolated *lead tetracetate* $Pb(C_2H_3O_2)_4$, melting at c. 175°, and decomposing a little above that temperature.

Note.—The formula $PbO(OC_2H_3O)_2$ said to be assigned by Jacquelain to the salt obtained by him (vol. iii. p. 130, col. 2, line 28 from top; and p. 131, col. 2, line 24 from bottom) should have been given as $PbO_2(C_4H_3O_3)_2$ *old notation.*

Plumbates (vol. iii. p. 132). Kassner (*Ar. Ph.* [3] 28, 109; *abstract* in *C. J.* 58, 561 [1890]) describes plumbates of Ba, Ca, and Sr. Regarding the dissociation of Ca plumbate, *v.* Le Chatelier (*C. R.* 117, 109; *abstract* in *C. J.* 64 [11], 524 [1893]).

Lead oxyiodides (vol. iii. p. 132). Gröger (*M.* 13, 510; *abstract* in *C. J.* 62. 1892) describes the compound $PbO.PbI_2$.

Lead, salts of (vol. iii. p. 132). The salt $Pb(C_2H_3O_2)_4$ (*v. supra*, *Red oxide of lead*) belongs to the type PbX^{I}_4, to which form $PbCl_4$ also belongs.

Lead, sulphide of (vol. iii. p. 133). According to Hannay (*C. J. Proc.*, Nos. 139 and 141 [1894]), when air is passed into molten PbS, one half of the lead remains as lead, and one half is volatilised, and deposited as PbS; H. accounts for this change by supposing the reaction to be $2PbS + O_2 = Pb + PbS.SO_2$, the volatile $PbS.SO_2$ being decomposed in the colder part of the apparatus to PbS and SO_2.

Lead sulphobromide and sulphochloride (vol. iii. p. 133). Parmentier (*C. R.* 114, 298; *abstract* in *C. J.* 62, 685 [1892]) obtained the compounds $PbS.PbBr_2$ and $PbS.PbCl_2$, by dissolving the halides in their acids and shaking the liquids while H_2S was passed over the surfaces of the solutions.

LITHIUM (vol. iii. p. 147). Guntz (*C. R.* 117, 732 [1893]) recommends to use a mixture of equal weights of LiCl and KCl, for the electrolytic preparation of the metal; the mixture melts at 450° and the m.p. decreases as electrolysis proceeds. (For details as to size of electrodes, strength of current, &c., *v. abstract* in *C. J.* 66 [11], 91 [1894].) Holt a. Sims, *C. J.* 65, 443 [1894], find that traces of a peroxide are formed, along with Li_2O, by burning Li in O.

Lithium, amide of, $LiNH_2$. Formed by gently heating clean Li in a stream of NH_3 until violent action ceases, and then heating to c. 400° until the reaction is finished. A white, crystalline, transparent solid; melts between 380° and 400°; decomposes in cold water slowly, giving LiOHAq and NH_3; decomposed by heating in air, but without taking fire (Titherley, *C. J.* 65; 504 [1894]; *q. v.* for further reactions).

Lithium, bromide of (vol. iii. p. 150). The hydrates $LiBr.xaq$, where x = 1 and 2, are described by Bogorodsky (*J. R.* 25, [illegible] [1893]).

Lithium, chloride of (vol. iii. p. 150). For $LiCl.aq$ and $LiCl.2aq$ *v.* Bogorodsky (*l.c.*). For the *double compounds* $LiCl.MCl_2.xaq$, where

M = Cu, Cd, Fe, Mn, or Ni; v. Chassevant (C. R. 114, 646; 115, 113; *abstracts* in C. J. 62, 118, 1373 [1892]).

Lithium, fluoride of (vol. iii. p. 150). Poulenc (*Bl.* [3] 11, 15 [1894]) obtained LiF in regular octahedra by heating the amorphous fluoride with KHF_2 and KCl, and washing with water; sl. sol. water, insol. 95 p.c. alcohol; melts at c. 1000° in H, and partially volatilises at 1100°–1200°.

Lithium, hydroxide of (vol. iii. p. 150). For the freezing-points of aqueous solutions of LiOH v. Pickering (*C. J.* 63, 899 [1893]).

Lithium, nitride of. Ouvrard (*C. R.* 114, 120 [1892]) obtained a black solid, probably Li_3N, by heating commercial Li to dull redness in N.

Lithium, oxides of (vol. iii. p. 151). Almost the only product of heating Li in O is Li_2O; only traces of a peroxide are formed (Holt a. Sims, *C. J.* 65, 443 [1894]).

MAGNESIUM (vol. iii. p. 157). Burton a. Vorce (*Am.* 12, 219 [1890]) obtained the value 24·22 (O = 15·96) for at. w., by converting pure Mg into $Mg(NO_3)_2$ and this to MgO. The molecule of Mg in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). Mg crystallises in holohedral hexagonal forms, $a:c = 1:1·6202$, isomorphous with Zn and Be (B. a. V., *l.c.*).

According to Montemartini (*G.* 22, 384, 397, 426 [1892]), a considerable quantity of H is given off when Mg interacts with HNO_3Aq (c. 13 p.c.); the quantity of NH_3 formed increases with concentration of the acid up to 40 p.c. HNO_3, after which it decreases. Mg burns in NO at a dull red heat (Sabatier a. Senderens, *C. R.* 115, 236 [1892]). Giorgis (*G.* 21, 510 [1891]) says that Mg dissolves in water saturated with CO_2; that H is given off, and crystals of $MgCO_3.3aq$ are deposited. For the interactions of Mg and chlorides v. Seubert a. Schmidt (*A.* 267, 218; *abstract* in *C. J.* 62, 776 [1892]). Winkler has made an extended examination of the interactions of Mg and oxides (*B.* 23, 44, 120, 772, 2642; 24, 873, 1966; *abstracts* in *C. J.* 58, 331, 451, 693, 1372 [1890]; 60, 801, 1155 [1891]).

Magnesium, bromide of (vol. iii. p. 159). Beketoff (v. *abstract* in *C. J.* 62, 762 [1892]) gives H.F. $[Mg,Br^2] = 121,700$. The *double salt* $2MgBr_2.PbBr_2.16aq$ is described by Otto a. Drewes (*Ar. Ph.* 229, 585; *abstract* in *C. J.* 62, 566 [1892]).

Magnesium, chloride of (vol. iii. p. 159). Skinner (*C. J.* 61, 341 [1892]) gives the boiling-points of solutions of $MgCl_2$ in water and alcohol, from c. 4·5 to c. 14·5 p.c. $MgCl_2$.

Magnesium, iodide of (vol. iii. p. 161). Beketoff (*l.c.*) gives H.F. $[Mg,I^2] = 84,800$.

Magnesium, nitride of (vol. iii. p. 161). For description of an experiment to demonstrate the formation of Mg_3N_2 v. Merz (*B.* 24, 3,940; *abstract* in *C. J.* 62, 409 [1892]).

Magnesium, oxide of (vol. iii. p. 161). MgO is unchanged at c. 1750° (Read, *C. J.* 65, 313 [1894]); heated in the electric furnace, it melts with a current of 70 volts and 350 ampères (Moissan, *C. R.* 115, 1034; *cf. C. R.* 116, 1429 [1892–3]). Richards a. Rogers (*P. Am. A.* 28, 200 [1893]) found that MgO, prepared by evaporating $MgCO_3$ or Mg, with HNO_3Aq and heating very strongly, retained c. 10 times its volume of gas, chiefly O and N.

Magnesium, silicides of (vol. iii. p. 162). Regarding the formation of compounds by heating together Mg and Si, v. Winkler (*B.* 23, 2642; *abstract* in *C. J.* 58, 1373 [1890]).

MANGANESE (vol. iii. p. 177). Moissan (*C. R.* 116, 349 [1893]) obtained Mn containing 4 to 5 p.c. C, by fusing MnO with charcoal (keeping MnO in excess) by means of a current of 60 volts and 300 ampères. Prelinger (*M.* 14, 353; *abstract* in *C. J.* 66 [ii], 49 [1894]) prepared pure Mn by heating Mn amalgam (formed by electrolysing $MnCl_2Aq$ using a cathode of Hg) in pure H.

Mn is described by P (*l.c.*) as a grey porous metal; unchanged in dry air; reacts slowly with cold, rapidly with warm, water; dissolves in NH_4ClAq giving off NH_3 and H; S.G. 7·4212 referred to water at 4°. Moissan (*C. R.* 116, 1429 [1893]) found that Mn volatilises readily in the electric furnace, using a current of 80 volts and 380 ampères. Montemartini (*G.* 22, 384, 397, 426 [1892]) says that the gaseous products of the interaction of Mn and HNO_3Aq are H, NH_3, N, and N_2O. Finely divided Mn reacts with CO at c. 400°, producing MnO and C (Guntz, *C. R.* 114, 115 [1892]).

Manganese, alloys of. The presence of 0·5 p.c. Mn in iron or steel scarcely affects the properties, except by slightly increasing the tenacity and malleability; a very hard tool-steel is formed with c. 1½ p.c. Mn. Alloys with iron containing from 7 to 30 p.c. Mn are extremely hard and tough.

Manganese, amalgams of (vol. iii. p. 179). Prelinger (*M.* 14, 353; *abstract* in *C. J.* 66 [ii], 49 [1894]) prepared Mn_2Hg_5 by passing a current from a kathode of Hg through saturated $MnCl_2Aq$ to an anode of C, or Pt-Ir, in a porous vessel, washing in running water, squeezing out excess of Hg, and drying in H over $CaCl_2$. By heating gently in a stream of pure, dry H, pure Mn was obtained.

Manganous chloride (vol. iii. p. 179). Chassevant (*A. Ch.* [6] 30, 5 [1893]) describes several *double salts* of $MnCl_2$; viz. $MnCl_2.AmCl.2aq$, $MnCl_2.2AmCl.aq$, and $MnCl_2.LiCl.3aq$. For the *double salts* $M.KCl.2aq$, $M.CsCl.2aq$; $M.2XCl.2aq$, $X = NH_4$, Cs, Rb; $2M.MgCl_2.12aq$ ($M = MnCl_2$), v. Saunders (*Am.* 14, 127; *abstract* in *C. J.* 62, 780 [1892]).

Manganic chlorides (vol. iii. p. 180). Regarding the composition of the chloride in the solution obtained by dissolving MnO_2 in HClAq, v. Vernon (*P. M.* [5] 31, 469), and Pickering (*P. M.* [5] 33, 284) (*abstracts* in *C. J.* 62, 19, 687 [1892]).

Manganese peroxide (vol. iii. p. 183). Regarding the compositions of the hydrated oxides, approximately $MnO_2.xaq$, prepared by different methods, v. Gorgeu (*Bl.* [3] 4, 16 [1891]). G. (*C. R.* 110, 857; *abstract* in *C. J.* 58, 946 [1890]) gives some details regarding the interaction of $MnO_2.xaq$ and H_2O_2Aq. Heated in the electric furnace, MnO_2 melts, gives off O, and leaves MnO (Moissan, *C. R.* 115, 1034 [1892]). Mn_2O_3 is said to be formed by heating MnO_2 to c. 400° in NO (Sabatier a. Senderens, *C. R.* 114, 1476 [1892]). McLeod (*C. J.* 65, 202 [1894]) has confirmed his former observation that Cl is given off when MnO_2 and $KClO_3$ are heated together. Regarding compounds of MnO_2 with basic oxides, *v.* Rousseau (*C. R.* 112, 525; 114, 72; 116, 1060; *abstracts* in *C. J.* 60, 645 [1891]; 62, 569 [1892]; 64 [11], 416 [1893]).

Permanganates (vol. iii. p. 186). Regarding the interaction of permanganates with H_2O_2Aq, *v.* Gorgeu (*C. R.* 110, 958; *abstract* in *C. J.* 58, 1062 [1890]). Klobb (*Bl.* [3] 3, 508; *abstract* in *C. J.* 58, 947 [1890]) describes compounds of NH_3 with permanganates of Cd, Cu, Ni, and Zn.

Barium permanganate $BaMn_2O_8$ (the formula is wrongly printed $BaMnO_4$ in vol. iii. p. 186). For the preparation of this salt from $KMnO_4Aq$ and $Ba(NO_3)_2Aq$ *v.* Muthmann (*B.* 26, 1016; *abstract* in *C. J.* 64 [11], 324 [1893]).

Calcium permanganate. The formula given on p. 186 of vol. iii. is wrong; it should be $CaMn_2O_8.5H_2O$.

Potassium permanganate (vol. iii. p. 186). Tivoli (*G.* 19, 630 [1890]) gives the following as the reactions that occur when pure AsH_3 is passed into dilute $KMnO_4Aq$: (1) $2KMnO_4Aq + AsH_3 = K_2HAsO_4Aq + Mn_2O_3 + H_2O$; (2) $2KMnO_4Aq + AsH_3 = K_2HAsO_3Aq + 2MnO_2 + H_2O$.

Silver permanganate (vol. iii. p. 187). $AgMnO_4$ decomposes slowly at the ordinary temperature, rapidly at 100°, and very rapidly at 125° (Gorgeu, *C. R.* 114, 912; *abstract* in *C. J.* 62, 942 [1892]).

Manganous sulphide (vol. iii. p. 188). The pp. produced by adding $(NH_4)HSAq$ to an ammoniacal solution of a Mn salt, after washing in an atmosphere of H_2S and drying in CO_2 at 70°, is MnS; S.G. $\frac{17°}{17°} = 3{\cdot}55$. By heating to 300°–320°, or by leaving in contact with $(NH_4)HSAq$ for some days, the reddish MnS becomes green without changing its composition; the green form of MnS is crystalline, S.G. $\frac{17°}{17°} = 3{\cdot}63$ (Antony a. Donnini, *G.* 23 [1], 560 [1892]).

MASRIUM. In 1892 (*C. J.* 61, 491) Richmond a. Husseinoff obtained indications of the existence of an element before unknown in specimens of Egyptian fibrous alums. The supposed new element gave reactions indicating analogies with Be, Ca, and Zn; the results obtained by decomposing the oxalate by heat led to the at. w. of c. 228. The authors suggested the name *masrium*, from the Arabic name for Egypt.

MERCURAMMONIUM COMPOUNDS (vol. iii. p. 206).

Mercuro-ammonium salts $NH_{4-x}Hg_xX$ (vol. iii. p. 207). Barfoed's conclusion that these supposed compounds are really mixtures of mercuri-compounds and Hg is confirmed by Pesci (*G.* 21 [11], 569 [1891]). The product of the interaction of HgCl and NH_3Aq, described as *dimercuro-ammonium chloride* $NH_2Hg_2.Cl$ in vol. iii. (p. 208), leaves metallic Hg when treated with ammoniacal $(NH_4)_2SO_4Aq$, according to P. When the reaction of HgCl with NH_3Aq proceeds out of the light, P. says that the change is $2Hg_2Cl_2 + 4NH_3Aq = (NHg_2)Cl.NH_4Cl + 2NH_4ClAq + 2Hg$. Similarly the reaction of NH_3Aq with Hg_2SO_4 produces a double compound of dimercuro-ammonium sulphate $((NHg_2)_2SO_4.(NH_4)_2SO_4)$ and Hg; and $(NHg_2)NO_3.NH_4NO_3$ and Hg are formed, according to P., when $HgNO_3Aq$ is treated with NH_3Aq.

Mercuri-ammonium salts $NH_2Hg.X$. Regarding the conditions of formation of compounds of mercuri-ammonium chloride $NH_2Hg.Cl$ (vol. iii. p. 208) with $HgCl_2$ and $NH_4(Hg_2O)Cl$, *v.* Balestra (*G.* 21 [11], 294; *abstract* in *C. J.* 62, 276 [1892]).

Dimercuri-ammonium salts NHg_2X (vol. iii. p. 209). Pesci (*G.* 20, 485 [1890]) has examined the conditions of formation of various salts of this class, especially the *nitrate* $NHg_2.NO_3$ and compounds of this with NH_4NO_3. The *sulphate* $(NHg_2)_2SO_4.2aq$ was formed by saturating conc. NH_3Aq with $HgSO_4$, allowing the solution to evaporate in an atmosphere of NH_3 over CaO, and collecting the first crop of crystals; various compounds of $(NHg_2)_2SO_4$ with $(NH_4)_2SO_4$ are also described (*v. abstract* in *C. J.* 60, 268 [1891]).

MERCURY (vol. iii. p. 212). Heycock a. Neville's results (*C. J.* 57, 376 [1890]) show that some condensation from monatomic molecules perhaps occurs in dilute solutions of Hg in tin. For corrected tables of the vapour pressures of Hg for each 10° from 180° to 480°, and each 1° from 330° to 360°, *v.* Young (*C. J.* 59, 629 [1891]).

Jäger (*W.* 48, 209 [1893]) recommends to prepare pure Hg by converting Hg that has been distilled *in vacuo* into $HgNO_3$ and electrolysing a solution of the salt, using Pt as cathode and distilled Hg as anode. Shenstone (*C. J.* 61, 452 [1892]) noticed that Hg adheres to glass when brought into contact with Cl, Br, or I. Montemartini (*G.* 22, 384, 397, 426 [1891]) finds that the amount of NO produced by the interaction of Hg and HNO_3Aq decreases as concentration of the acid increases; that NO_2 is produced with acid more conc. than 27·5 p.c. HNO_3, $HgNO_3$ is formed with 25 p.c. acid, but $Hg(NO_3)_2$ with 50 to 70 p.c. acid; no NH_3 is formed with 27 and 50 p.c. acid.

Mercuric bromide (vol. iii. p. 215). $HgBr_2$ boils at 325°, according to Freyer a. V. Meyer (*Zeit. f. anorg. Chemie*, 2, 1 [1892]).

Mercurous chloride (vol. iii. p. 215). Harris a. V. Meyer have re-determined the V.D. of calomel at 448° and 518°; the value obtained was 117·5. H. a. M. obtained considerable quantities of Hg and $HgCl_2$ by allowing the vapours obtained by heating calomel to c. 465° to diffuse along a glass tube; also by heating calomel at 420° for half an hour in a distillation flask at 33 mm. pressure. By heating calomel to 240°–260°, and bringing a piece of KOH, which had been heated to c. 250°, into the vapour, they noticed that the surface of the KOH at once became covered with yellow HgO; they also found that a piece of gold leaf held for a moment in the vapour was amalgamated (if kept for some time in the hot vapour the yellow colour was restored). H. a. M. think their results leave no doubt that the vapour obtained by heating calomel is $Hg + HgCl_2$, and that the molecular formula of calomel is Hg_2Cl_2.

The reaction of Hg_2Cl_2 with NH_3Aq gives $(NHg_2)Cl.NH_4Cl$ and Hg, according to Pesci (*v. supra.* MERCURO-AMMONIUM SALTS).

Mercuric chloride (vol. iii. p. 217). $HgCl_2$ boils at 307° (Freyer a. V. Meyer, *Zeit. f. anorg. Chemie*, 2, 1 [1892]). The white substance produced by the reaction of $HgCl_2$Aq with a silver photographic image, or with pulverulent Ag, is $HgAgCl_2$, according to Jones (*S. C. I.* 12, 983; *abstract* in *C. J.* 66 [11], 188 [1894]).

Mercuric cyanide; for an account of the conditions of formation and properties of the *double mercury-zinc cyanide*, v. Dunstan (*C. J.* 61, 666 [1892]).

Mercury, haloid compounds of (vol. iii. p. 219). Wells (*Am. S.* [3] 44, 221; *abstract* in *C. J.* 64 [11], 68 [1893]) describes a number of double compounds of mercury and cæsium halides; the compounds belong to the forms (1) Cs_3HgX_5, (2) Cs_2HgX_4, (3) $Cs_2Hg_3I_8$, (4) $CsHgX_3$, (5) $CsHg_2X_5$, (6) $CsHg_5X_{11}$; X = Cl, Br or I; in some cases the total X atoms comprise two different halogens.

Mercury hydrosulphide; for experimental attempts to prepare a definite compound, v. Linder a. Picton (*C. J.* 61, 123 [1892]).

Mercury phosphide (vol. iii. p. 223). By heating Hg and PI_2 in a sealed tube for many hours at 275°–300°, and removing HgI_2 by treatment with KIAq, Granger (*C. R.* 115, 229 [1892]) obtained Hg_3P_2 in lustrous, metal-like, hexagonal crystals, appearing red by transmitted light, and giving a brown powder. The compound gives Hg and P when heated; heated in air it burns; detonates when mixed with $KClO_3$ and struck; burns in Cl; dissolved by *aqua regia*.

Mercurous sulphide (vol. iii. p. 224). Antony a. Sestini (*G.* 24 [1], 193 [1894]) obtained a black powder by passing dry H_2S, diluted with CO_2, over dry Hg_2Cl_2 or $Hg(C_2H_3O_2)$, kept at −10°; when freshly prepared the black powder was scarcely changed in dry HCl at −18°, but at a somewhat higher temperature (below 0°) Hg_2Cl_2 was quickly formed. The substance dissolved in cold K_2SAq or Na_2SAq, but when temperature rose above 0° the solution became turbid and ppd. Hg. A. a. S. think their results show that Hg_2S exists at low temperatures (*abstract* in *C. J.* 66 [11], 318 [1894]).

Mercury sulphochloride (vol. iii. p. 225). The compound $2HgS.HgCl_2$ is formed, according to Colson (*C. R.* 115, 657 [1892]), by passing H_2S into a solution of $HgCl_2$ in dry benzene.

MOLYBDENUM (vol. iii. p. 421). Smith a. Maas (*A. C. J.* 15, 397 [1893]) obtained the mean value 95·85 (O = 15·96) for the at. w. of Mo, by heating Na_2MoO_4 in a current of dry HCl and weighing the NaCl that remained ($MoO_3.2HCl$ and H_2O were formed and removed). Smith a. Oberholtzer (*Zeit. f. anorg. Chemie*, 5, 63 [1893]) say that a mixture of $MoOCl_4$ and $Mo(CO)Cl_4$ is formed by heating Mo to 150°–200° in $COCl_2$; and that $Mo_3S_7Cl_4$ is produced by heating Mo to redness in S_2Cl_2. Mo is said to ppt. Ag from $AgNO_3$Aq, Au from $AuCl_3$Aq, HgCl and then Hg from $HgCl_2$Aq, and Cu from solutions of its salts (Smith, *Zeit. f. anorg. Chemie*, 1, 360 [1891]). Montemartini (*G.* 22, 384, 397, 426 [1891]) finds that no NH_3 is formed in the interaction of Mo and HNO_3Aq with from 3 to 70 p.c. HNO_3; the most vigorous action occurs with acid c. 50 p.c., but the whole of the metal is not oxidised to MoO_3, a nitrate being probably formed; the gaseous products are NO and NO_2, the quantity of NO decreasing as the concentration of the acid increases.

Molybdenum, carbides of. By heating a mixture of MoO_2 and charcoal in the electric furnace, Moissan (*C. R.* 116, 1225 [1893]) obtained a very hard carbide, containing from 9·77 to 9·9 p.c. C; S.G. 8·6.

Molybdenum sesquioxide (vol. iii. p. 431). Heating Mo_2O_3 in NO produces MoO_2 (Sabatier a. Senderens, *C. R.* 114, 1429 [1892]).

Molybdenum trioxide (vol. iii. p. 432). MoO_3 partially volatilises, and is partially reduced to one of the blue oxides, at c. 1750° (Read, *C. J.* 65, 313 [1894]). According to Smith a. Oberholtzer (*Zeit. f. anorg. Chemie*, 4, 236 [1893]), the products of heating MoO_3 in HBr are (1) $MoO_3.3HBr$, and (2) $Mo_2O_3Br_4$; when HI is used and the temperature kept at 105°–120°, a blue oxide $Mo_3O_8.x$aq is formed; HF at 300°–400° forms $Mo_2O_3F_4$ (*v. abstract* in *C. J.* 64 [11], 471 [1893]). Cammerer (*Chem. Zeit.* 15, 957; *abstract* in *C. J.* 62, 944 [1892]) says that $2MoO_3.H_2O_2.H_2O$ is formed by boiling MoO_3 with H_2O_2Aq.

Molybdenum, oxybromides of (vol. iii. p. 433). Smith a. Oberholtzer (*Zeit. f. anorg. Chemie*, 4, 236 [1893]) describe $Mo_2O_3Br_4$; square plates, colour of $KMnO_4$. Formed, along with $MoO_3.3HBr$, by heating MoO_3 in HBr.

Molybdenum, oxychlorides of (vol. iii. p. 433). For the products of the interaction of MoO_2Cl_2 and NH_3, v. Smith a. Lehner (*Zeit. f. anorg. Chemie*, 4, 374; *abstract* in *C. J.* 64 [11], 529 [1893]).

Molybdenum, oxycyanide of. By dissolving MoO_2 in KCyAq, and adding a strong acid, Péchard (*C. R.* 118, 804 [1894]) obtained MoO_2Cy_2. Easily decomposed by contact with acids; *double compounds* with KCy and AgCy are also described.

Molybdenum, oxyfluorides of (vol. iii. p. 433) For $Mo_2O_3F_4$, a white, crystalline, deliquescent solid, obtained by heating MoO_3 in HF at 300°–400°, v. Smith a. Oberholtzer (*l.c.*).

Molybdenum, thiochloride of. For $Mo_3S_7Cl_4$, v. S. a. O. (*l.c.* 5, 63).

Molybdates, and derivatives thereof (vol. iii. p. 423). For compounds of molybdates of NH_4 and K with SO_2 and SeO_2, v. Péchard (*C. R.* 116, 1441; 117, 104; *abstracts* in *C. J.* 64 [11], 530 [1893]).

Permolybdates. By the reaction of H_2O_2Aq with $K_2Mo_3O_{10}$Aq, Péchard (*C. R.* 112, 720; *abstract* in *C. J.* 60, 988 [1891]) obtained *potassium permolybdate* $K_2Mo_2O_8$. 4aq; the corresponding NH_4 salt was also formed.

Arseno-molybdates (vol. iii. p. 425). For salts of this class, v. Friedheim (*Zeit. f. anorg. Chemie*, 2, 314; 6, 11, 27; *abstracts* in *C. J.* 64 [11], 283; 66 [11], 238 [1893–4]).

Iodomolybdates. A great many salts of the form $xMoO_3.yI_2O_5.zMO$ are described by Blomstrand (*Zeit. f. anorg. Chemie*, 1, 10; *abstract* in *C. J.* 64 [11], 122 [1893]).

Phosphomolybdates (vol. iii. p. 426). Friedheim (*Zeit. f. anorg. Chemie*, 4, 275; 6, 11, 27; *abstracts* in *C. J.* 64 [11], 472; 66 [11], 238 [1893–4]) describes several salts of this class.

Fluomolybdates (vol. iii. p. 425), v. Piccini (*Real. Acad. Lincei*, 7 [1], 267; *abstract* in *C. J.* 62, 784 [1892]), and Mauro (*l.c.*, 1892 [1], 194; *abstract* in *C. J.* 64 [11], 124 [1893]).

NICKEL (vol. iii. p. 498). The at. w. has been re-determined (1) by Schützenberger, by reducing oxides of Ni in H (*C. R.* 114, 1149 [1892]); (2) by Winkler, by estimating Cl in $NiCl_2$ prepared from electrolytically deposited Ni (*Zeit. f. anorg. Chemie*, 4, 10 [1893]). Schützenberger's values varied from 58·52 to 59·8; Winkler's mean value from the gravimetric determinations was 58·903, and from the volumetric determinations 58·910 (Cl = 35·37, Ag = 107·66). Krüss a. Schmidt (*Zeit. f. anorg. Chemie*, 2, 235 [1892]) insist that the substance called nickel is not an element, but Winkler (*l.c.*) controverts this statement (*v. abstracts* in *C. J.* 64 [11], 212, 469 [1893]). The molecule of Ni in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). Schützenberger (*C. R.* 113, 177 [1891]) says that a volatile compound is formed by passing dry HCl over finely divided Ni heated to dull redness. Montemartini (*G.* 22 [1], 250; *abstract* in *C. J.* 62, 1278 [1892]) gives the quantities of NH_3, N_2O, N, and HNO_2 (no NO) produced by the reaction of excess of HNO_3Aq (27·5 p.c.) with Ni. Heated to 200° in NO, the oxide NiO is formed without any Ni_2O_3 (Sabatier a. Senderens, *C. R.* 114, 1429 [1892]). By passing NO_2, diluted with N, over reduced Ni, *nitro-nickel* (? Ni_2NO_2) is obtained; it resembles nitro-cobalt (*q. v.*, p. 908) (S. a. S., *Bl.* [3] 9, 669 [1893]).

Nickel carbonyl $Ni(CO)_4$. (*Nickel carbonoxide*, vol. iii. p. 501.) Mol. w. was confirmed by Mond a. Nasini (*Z. P. C.* 8, 150 [1891]), by finding the depression of the freezing-point of benzene. S.G. 1·35613 at 0°, 1·27132 at 36° (water at 4° = 1); S.G. at b.p. = 1·25406; molecular volume = 136·04; critical temp. = 151°. For some reactions *v.* Berthelot (*C. R.* 112, 1343; *abstract* in *C. J.* 60, 1427 [1890]).

Nickel, chloride of (vol. iii. p. 501). A volatile substance, decomposed by heating, is said to be formed by passing dry HCl over dry $NiCl_2$ at dull redness (Schützenberger, *C. R.* 113, 177; *v. abstract* in *C. J.* 60, 1429 [1890]). Chassevant (*A. Ch.* [6] 30, 5 [1893]) describes the *double compounds* $NiCl_2.AmCl.6aq$ and $NiCl_2.KCl.3aq$.

Nickel, fluoride of (vol. iii. p. 502). Poulenc (*C. R.* 114, 1426 [1892]) obtained amorphous NiF_2 by heating $NiCl_2$ with excess of NH_4F, and washing away NH_4Cl with boiling alcohol; by heating in HF to 1200°-1300°, the amorphous NiF_2 became crystalline, forming green prisms, S.G. 4·63, not acted on by warm HNO_3Aq, HClAq, or H_2SO_4Aq. Heated in air, NiF_2 gives NiO; heated with S it gives NiS; and with H it is reduced to Ni (for other reactions, *v. abstract* in *C. J.* 62, 1159 [1892]). The *double salt* $NiF_2.KF$ is formed by heating $NiCl_2$ with KHF_2, and washing away KCl by water (P., *C. R.* 114, 746 [1892]).

Nickel monoxide (vol. iii. p. 502). NiO melts and forms green crystals in the electric furnace (Moissan, *C. R.* 115, 1034 [1892]). NiO occludes small quantities of N and O (Richards a. Rogers, *P. Am. A.* 28, 200 [1893]).

Nickel sesquioxide (vol. iii. p. 502). Ni_2O_3 fuses, gives up all its O, and leaves Ni at c. 1750° (Read, *C. J.* 65, 313 [1894]).

Nickel peroxide (vol. iii. p. 503). Campbell a. Trowbridge (*J. Anal. and App. Chem.* 7. 301; *abstract* in *C. J.* 66 [11], 238 [1894]) conclude that an oxide with more O than Ni_2O_3 can be obtained by ppg. $NiSO_4Aq$ by Na_2CO_3Aq in presence of Br at different temperatures.

Nickel monosulphide (vol. iii. p. 508). Regarding the oxidation of this salt in air, to $NiSO_4.6NiO$, &c., *v.* P. de Clermont (*C. R.* 117, 229; *abstract* in *C. J.* 64 [11], 528 [1893]).

NIOBIUM (vol. iii. p. 505). Nb_2O_5 is not changed at c. 1750° (Read, *C. J.* 65, 313 [1894]). Piccini (*Zeit. f. anorg. Chemie*, 2, 21 [1892]) has prepared *potassium fluoxyperniobate* $NbO_2F_3.2KF.aq$.

NITRAMIDE $NO_2(NH_2)$. Thiele a. Lachman (*B.* 27, 1909 [1894]) obtained this compound by throwing $NO_2.NK.CO_2K$ (potassium nitro-carbamate) into a mixture of ice and excess of H_2SO_4, extracting with ether, and evaporating in a stream of air. Crystallises in clear prisms, which melt at 72° with decomposition; decomposed instantly to N_2O and H_2O by alkalis, alkali carbonates, borax, or Na acetate.

NITRATES (vol. iii. p. 509). Rousseau a. Tite (*C. R.* 115, 174 [1892]) find that many basic nitrates are completely decomposed by heating with water at 150°-200°. Regarding the formation of basic nitrates of Cd, Ca, Ni, and Zn, *v.* R. a. T. (*C. R.* 114, 1184); Riban (*C. R.* 114, 1357); and Werner (*C. R.* 115, 169); (*abstracts* in *C. J.* 62, 1156, 1157, 1276 [1892]).

NITRIC ACID (vol. iii. p. 517). Regarding the colours produced by diluting red fuming HNO_3Aq *v.* Marchlewski (*B.* 24, 3271 [1891]). For revised tables showing the composition of HNO_3Aq of different concentrations *v.* Lunge a. Rey (*S. C. I.* 1891. 543). Regarding the magnetic rotations of HNO_3Aq *v.* Perkin (*C. J.* 63, 57 [1893]). Hall (*Am.* 13, 554) has examined the rate of production of H and O, and the effect on the concentration of the acid, by the slow and steady electrolysis of HNO_3Aq (*abstract* in *C. J.* 62, 680 [1892]). The interactions of HNO_3Aq with many metals have been examined by Montemartini (*G.* 22 [1], 250, 277, 384, 397, 426 [1891]; *abstracts* in *C. J.* 62, 1278, 1402 [1892]), Veley (*S. C. I.* 10, 206; and elsewhere), and others; the results are noted under various metals. Pickering (*C. J.* 63, 436 [1893]) has isolated the hydrates $HNO_3.H_2O$ and $HNO_3.3H_2O$; the freezing-points of HNO_3Aq, from 1·82 to 86·19 p.c. HNO_3, are given by P.

NITROGEN (vol. iii. p. 556). S.G. of N (air = 1) = ·97209; 1 litre weighs 1·25749 g. (Rayleigh, *P. R.* 53, 134 [1893]). $\mu_D = 1{\cdot}2053$ at −190° (liquid N, containing 5 p.c. O) (Liveing a. Dewar, *P. M.* [5] 36, 928 [1893]). Absorption coefficient in alcohol, *v.* Henrich (*Z. P. C.* 9, 435 [1892]). Diffusion in water, *v.* Duncan a. Hoppe-Seyler (*Zeit. physiol. Chemie*, 17, 147 [1893]).

Preparation of pure nitrogen. Threlfall (*P. M.* [5] 35, 1 [1893]) gives minute directions for preparing pure N by passing air and NH_3 over hot Cu, and absorbing traces of O by $CrCl_2Aq$; exact directions for preparing the $CrCl_2Aq$ are given, and the paper contains numerous details regarding the purifications of the reagents used in the process.

Supposed allotropic form of nitrogen. Threlfall (*l.c.*) has repeated experiments on sparking extremely pure N (*v.* vol. iii. p. 557); no condensation occurred down to −10° and c. 8 mm.

pressure, but when Hg is present a compound of N and H is formed (probably Hg_3N_2, v. vol. iii. p. 221). Regarding the *fixation of nitrogen by growing plants*, v. Beyerinck, also Schloesing a. Laurent (*abstracts* in *C. J.* 62, 1019, 1021 [1892]).

Nitrogen, hydrides of (vol. iii. p. 559). *Hydrazoic acid* N_3H. For new methods of preparing N_3H v. Curtius (*B.* 24, 3341; 26, 1263; *abstracts* in *C. J.* 62, 112; 64 [11], 463 [1892-3]). Wislicenus (*B.* 25, 2084 [1892]) has obtained N_3H by the interaction of NH_3 and N_2O. From $\frac{1}{4}$ g. to $\frac{1}{2}$ g. Na is heated in a stream of NH_3 until all is converted into $NaNH_2$; a current of dry N_2O is then passed over the $NaNH_2$ at 150°–250° as long as NH_3 is given off ($2NaNH_2 + N_2O = NaN_3 + NaOH + NH_3$). By dissolving the product in water, filtering, decomposing by dilute H_2SO_4Aq, and distilling, N_3HAq is obtained.

The following salts are described by Curtius (*B.* 24, 3341; *abstract* in *C. J.* 62, 112 [1892]): $(NH_4)N_3$, $Pb(N_3)_2$, HgN_3, NaN_3.

Nitrogen, iodides of (vol. iii. p. 560). Diiodamine, NHI_2, is the product of adding excess of NH_3Aq to a conc. solution of I in conc. KIAq; by suspending NHI_2 in water, and adding an ammoniacal solution of $AgNO_3$ or Ag_2O, a black compound $NAgI_2$ is obtained which explodes when dry (Szuhay, *B.* 26, 1933; *abstract* in *C. J.* 64 [11], 568 [1893]; *cf.* Selivanoff, *B.* 27, 1012; *abstract* in *C. J.* 66 [11], 312 [1894]).

Nitrous oxide (vol. iii. p. 561). Ramsay a. Shields (*C. J.* 63, 833 [1893]) give the m.p. of N_2O as −102·3°, and the b.p. as −89·8°. Villard (*C. R.* 118, 1096 [1894]) gives the following data for the S.G. of liquid N_2O: ·9105 at 0°, ·885 at 5°, ·856 at 10°, ·804 at 17·5°, ·720 at 26·5°, ·640 at 32·9°, ·605 at 34·9°, ·572 at 36·3°. Liveing a. Dewar (*P. M.* [5] 34, 205 [1892]) give

$$\frac{\mu_D - 1}{d} = ·2634, \text{ and } \frac{\mu^2 - 1}{(\mu^2 + 2)d} = ·163 \text{ at } -90°.$$

Smith (*S. C. I.* 11, 867; 12, 10 [1893]) says that a regular stream of N_2O is obtained by heating to 240°–250° a mixture of 1 pt. dry $NaNO_3$ with c. $1\frac{3}{4}$ pt. dry $(NH_4)_2SO_4$. By passing N_2O, mixed with a little H, over Pd black, the H is entirely converted to H_2O, with formation of N (Montemartini, *Real. Acad. Lincei*, 7 [11], 219 [1892]).

Nitric oxide (vol. iii. p. 562). Very pure NO is obtained, according to Emich (*M.* 13, 73 [1892]), by the interaction of copper and a mixture of H_2SO_4 and HNO_3Aq. Emich (*l.c.*, p. 78) finds that NO is completely decomposed to N and O by passing over nets of Pt or Pd wire kept very hot by an electric current. Emich (*l.c.* p. 86) says that NO and O unite after being dried by long contact with P_2O_5; but Baker (*C. J.* 65, 611 [1894]) finds that *dry* NO and *dry* O do not combine at the ordinary temperature. Regarding the reactions between NO and metals and metallic oxides, v. Sabatier a. Senderens (*C. R.* 114, 1429; 1476; *abstracts* in *C. J.* 62, 1151, 1271 [1892]; results are noted under the different metals and oxides in *Addenda*).

Nitrogen dioxide (vol. iii. p. 565). For the reactions of NO_2 with various metals and oxides v. S. a. S. (*C. R.* 115, 236; *abstract* in *C. J.* 62, 1390 [1892]; results are noted under the different metals and oxides in *Addenda*).

Nitrogen tetroxide (vol. iii. p. 565). For preparation of N_2O_4, v. Cundall (*C. J.* 59, 1076 [1891]). C. (*l.c.*) has measured the dissociation of liquid N_2O_4 in $CHCl_3$ up to c. 25°; Ostwald (*C. J.* 61, 242 [1892]) shows that the dissociation follows van't Hoff's law for dilute solutions.

Nitrous acid (vol. iii. p. 567). Regarding the formation of HNO_2 in solution in HNO_3, v. Veley (*Pr.* 52, 27; *abstract* in *C. J.* 64 [11], 413 [1893]).

Hyponitrous acid (vol. iii. p. 568). Tanatar (*J. R.* 25, 342; *abstract* in *C. J.* 66 [11], 186 [1894]) prepared $Ag_2N_2O_2$ by adding CaO to fairly conc. KNO_2Aq in the ratio $CaO:KNO_2$, then an equivalent of solid $NH_2OH.HCl$, heating to 50°, letting stand for a few days at the ordinary temperature, filtering, acidifying with acetic acid, ppg. by $AgNO_3Aq$, dissolving $Ag_2N_2O_2$ in HNO_3Aq (which leaves AgCl), and ppg. again by Na acetate.

OSMIUM (vol. iii. p. 641). Os fuses readily in the electric arc in a carbon capsule; when fused it has a crystalline fracture, and scratches quartz, but is scratched by topaz (Joly a. Vèzes, *C. R.* 116, 577 [1893]).

Osmic acid (vol. iii. p. 646). Moraht a. Wischin (*Zeit. f. anorg. Chemie*, 3, 153; *abstract* in *C. J.* 64 [11], 380 [1893]) say that the black powder obtained by the interaction of acids and K_2OsO_4Aq (vol. iii. p. 645), when dried over P_2O_5 *in vacuo* till it ceases to lose weight, is osmic acid H_2OsO_4. M. a. W. describe the compound as a sooty-black powder, smelling of OsO_4 in moist air, but unchanged under water containing alcohol. By passing H_2S over H_2OsO_4 a violent reaction occurs, and $Os_2O_2S_3.H_2O$ is formed. Heated with conc. HClAq for many hours with a little alcohol, and evaporated, $Os_2Cl_7.7aq$ was obtained; an alcoholic solution of this substance with KClAq gave K_2OsCl_6 and the filtrate yielded $OsCl_3.3aq$; the substance Os_2Cl_7 is therefore supposed by M. a. W. to be a mixture of $OsCl_4$ and $OsCl_3$. By heating H_2OsO_4 with HIAq, violet-black crystals, probably OsI_4, were obtained. No action occurs when Os is heated with I, or with Br.

Potassium osmiamate (vol. iii. p. 645). Joly (*C. R.* 112, 1442 [1891]) prepares this salt by dissolving 100 pts. OsO_4 in a solution of 100 pts. KOH in 50 pts. H_2O, keeping the solution at c. 40°, and adding 40 c.c. NH_3Aq; after a time the brown liquid becomes colourless, and a yellow crystalline pp. is formed. J. gives the formula $KNOsO_3$ to this salt. Heated *in vacuo* it is rapidly decomposed above 200°, and at 440° almost all the N is given off, the solid products being K_2OsO_4, OsO_2, and $KOsO_3$ (*v. abstract* in *C. J.* 60, 1433 [1891]).

OXIDES (vol. iii. p. 658). Regarding the connections between the stability of oxides when heated and the periodic classification of the elements, *v.* Bailey (*C. J.* 65, 106, 321 [1894]).

OXYGEN (vol. iii. p. 703). *Atomic weight of oxygen* (vol. iii. p. 705). Dittmar a. Henderson (*C. N.* 67, 127, 139, 151, 164; *abstract* in *C. J.* 64 [11], 410 [1893]), from careful determinations made by passing H over hot CuO, and weighing the water and Cu produced, adopt the value 15·87 for the at. w. of O. By measurements of the combining volumes of O and H, combining the results with Rayleigh's determination of the S.G. of O, Scott (*T.* 184, 543 [1893]) got the value 15·862. The following values summarise the most recent determinations (*v.* D. a. H., *l.c.*), Cooke a. Richards, 15·868; Noyes, 15·885; Rayleigh (*Pr.* 45, 425 [1890]), 15·89; Keiser, 15·949; Leduc (*C. R.* 116, 1248 [1893]), 15·88; D. a. H., 15·87; Scott, 15·862. The value adopted in this *Dictionary*, 15·96, is almost certainly too high; the mean of the values obtained by C. a. R., N., R., D. a. H., and S., is 15·875.

The ratio of the combining volumes of O and H was determined by Scott (*l.c.*) to be 2·00245 : 1 (*v.* WATER, this vol. p. 861). S.G. of O referred to H = 15·882 (Rayleigh, *Pr.* 50, 448 [1892]). For an examination of the whole of the spectrum of O, *v.* Eisig (*W.* 51, 747: *abstract* in *C. J.* 66 [ii], 265 [1894]). Liveing a. Dewar (*P. M.* [5] 34, 205 [1892]) determined $\frac{\mu_D - 1}{d}$ to be ·1989, and $\frac{\mu^2 - 1}{(\mu^2 + 2)d}$ to be ·1265, at −182° (*cf.* Olszewski a. Witkowski; *abstract* in *C. J.* 64 [ii], 353 [1893]). For diffusion of O in water, *v.* Duncan a. Hoppe-Seyler (*Zeit. physiol. Chemie*, 17, 147 [1892]).

Regarding the division of O between H and CO when mixtures of these gases are exploded, *v.* Harker (*Z. P. C.* 9, 673 [1892]). *Dry* O does not combine with *dry* NO at the ordinary temperature (Baker, *C. J.* 65, 611 [1894]); nor with *dry* K or Na, even when these metals are distilled in the gas (Holt a. Sims, *C. J.* 65, 440 [1894]).

OZONE (vol. iii. p. 788). Regarding the conditions of ozonification of oxygen, *v.* Shenstone a. Priest (*C. J.* 63, 938 [1893]). Baker (*C. J.* 65, 611 [1894]) confirms the observation of Shenstone a. Cundall (*C. J.* 81, 610 [1887]) that *dry* O is ozonised as rapidly as moderately dry O.

PALLADIUM (vol. iii. p. 792). The at. w. of Pd has been re-determined (1) by Bailey a. Lamb (*C. J.* 61, 745 [1892]), by analyses of $Pd(NH_3Cl)_2$; (2) by Keller a. Smith (*Am.* 14, 423 [1892]), by ppg. Pd electrolytically from a solution of $Pd(NH_3Cl)_2$ in NH_3Aq; (3) by Joly a. Leidié (*C. R.* 116, 146 [1893]), by electrolysing K_2PdCl_4 in HClAq; (4) by Keiser a. Breed (*Am.* 16, 20 [1894]), by determining the ratio of Pd to Cl in $Pd(NH_3Cl)_2$. B. a. L. obtained the value 105·459; K. a. S. the value 106·35; J. a. L. the value 105·665; and K. a. B. the value 106·27 (Cl = 35·37; Ag = 107·66; N = 14·01; O = 15·96). The molecule of Pd in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). Regarding the preparation of pure Pd, *v.* the memoirs referred to *supra.* Pd absorbs O at 450°, forming Pd_2O (Neumann, *M.* 13, 40 [1892]), but when Pd sponge is heated in dry O till the weight is constant PdO is formed (Wilm, *B.* 25, 220 [1892]). Heated to 200° in NO, Pd sponge that has been saturated with H becomes incandescent and the NO is completely changed to H_2O and NH_3, but oxidation of the Pd does not occur (Sabatier a. Senderens (*C. R.* 114, 1429 [1892]). Regarding *palladium sulphides*, *v.* Petrenko-Kritschenko (*Zeit. f. anorg. Chemie*, 4, 247; *abstract* in *C. J.* 64 [ii], 475 [1893]). *Phosphopalladous compounds*, $PdCl_2.PCl_3$ and $PdCl_2.P(OH)_3$, are described by Fink (*C. R.* 115, 176; *abstract* in *C. J.* 62, 1285 [1892]). Vèzes (*C. R.* 115, 111) describes *potassium palladosochloronitrite* $K_2Pd(NO_2)_2Cl_2$ (*abstract* in *C. J.* 62, 1284 [1892]).

PHOSPHATES (vol. iv. p. 106). Rossel a. Frank (*B.* 27, 52) say that P is obtained by heating $NaPO_3$, or any phosphate of Ca or Mg, with Al in a current of H.

Dipotassium-hydrogen orthophosphate (vol. iv. p. 111). According to Standenmaier (*Zeit. f. anorg. Chemie*, 5, 383 [1893]), K_2HPO_4 cannot be isolated. S. (*l.c.*) describes *acid salts*, $K_5H_4(PO_4)_3.aq$, $K_7H_5(PO_4)_4.2aq$, and $KH_5(PO_4)_2$.

Thorium orthophosphates (vol. iv. p. 112). Volck (*Zeit. f. anorg. Chemie*, 6, 161 [1894]) obtained $Th(HPO_4)_2.aq$ by adding dilute H_3PO_4Aq to $ThCl_4Aq$.

Sodium pyrophosphate (vol. iv. p. 114). For a study of the reaction of HClAq with $Na_4P_2O_7$, *v.* Watson (*S. C. I.* 11, 224; *abstract* in *C. J.* 64 [ii], 272 [1893]).

ORTHOPHOSPHORIC ACID (vol. iv. p. 125). According to Watson (*C. N.* 68, 199 [1893]), H_3PO_4 is changed completely to $H_4P_2O_7$ at 255°–260°, and HPO_3 begins to form at 290°–300°.

PHOSPHORUS (vol. iv. p. 129). Regarding the action of light and heat on *ordinary phosphorus*, *v.* Retgers (*Z. P. C.* 5, 211; *abstract* in *C. J.* 66 [ii], [1894]).

Phosphorus hydride (vol. iv. p. 136). PH_3 and O react at a low pressure to form H_3PO_3 ($2PH_3 + 3O_2 = 2H_3PO_3$); when the gases are allowed to diffuse with one another at less than 50 mm. pressure, the reaction is $PH_3 + O_2 = H_2 + HPO_2$; slow oxidation at greater pressures proceeds approximately according to the equation $4PH_3 + 5O_2 = 2HPO_2 + 2H_3PO_3 + 2H_2$ (H. J. van de Stadt, *Z. P. C.* 12, 322 [1893]). According to van de S., explosion occurs at a certain low pressure, and this pressure depends much on the amount of moisture present, the moisture preventing and retarding the explosion. Kooij (*Z. P. C.* 12, 155 [1893]) has examined the rate of decomposition of PH_3 by heat. For the reaction of PH_3 with $AgNO_3Aq$ *v.* Vitali (*abstract* in *C. J.* 64 [ii], 206 [1893]).

Phosphoric oxide (vol. iv. p. 141). For details regarding the preparation of pure P_2O_5, and for methods of detecting traces of P in P_2O_5, *v.* Threlfall (*P. M.* [5] 35, 14 [1893]).

Phosphorus suboxide (vol. iv. p. 139). [illegible] (*B.* 27, 1257 [1894]) thinks that P_4O is formed by the interaction of P_2O_5 and NH_3.

Phosphorus, sulphides of (vol. iv. p. 145). Helff (*Z. P. C.* 12, 190 [1893]) confirms the statement that there are no definite compounds P_4S and P_2S; by heating together red P and S, he obtained P_4S_3, P_4S_7, P_3S_6, and P_2S_5.

Phosphorus, sulphoiodide of. Ouvrard (*C. R.* 115, 1301; *abstract* in *C. J.* 64 [ii], 164 [1893]) obtained P_2S_3I by heating PI_2 in H_2S at 110°–120°; also by evaporating a solution of the three elements in the proper proportion in CS_2 and heating the residue to 120° in an inert gas; also by dissolving I in a solution of P_2S_3 in CS_2. The compound crystallises from CS_2 in golden-yellow prisms; it is unchanged in dry air, but slowly decomposed in moist air, giving off H_2S; sl. sol. $CHCl_3$, C_6H_6, EtOH, or Et_2O; burns at c. 300°, giving P_2O_5, SO_2, and I; at c. 300° *in vacuo* it separates into I and P_2S_4; decomposed by hot water, and explosively by fuming HNO_3.

Potassium hypophosphates (vol. iv. p. 153). Bansa (*Zeit. f. anorg. Chemie*, 6, 128 [1894]) describes many *double salts* of $K_2H_2P_2O_6$ with $MH_2P_2O_6$, where M = Cd, Co, Cu, Mn, Ni, or Zn; also double salts $MK_2P_2O_6$, where M = Co or Ni. The double salt $K_2Na_2P_2O_6.2aq$ is also described (*abstract* in C. J. 66 [11], 279 [1894]).

Thallium hypophosphates. Joly (*C. R.* 118, 649 [1894]) obtained the *normal salt* $Tl_4P_2O_6$, and the *acid salt* $Tl_2H_2P_2O_6$ (*abstract* in *C. J.* 66 [11], 282 [1894]).

PLATINATES (vol. iv. p. 281).

Sodium thioplatinates. Schneider has obtained the salts Na_2PtS_2 and $Na_2S.PtS.2PtS_2$ (*J. pr.* [2] 48, 411 [1894]).

Platino-oxalates (vol. iv. p. 285). Regarding the constitutional formulæ of the K salts, *v.* Werner (*Zeit. f. anorg. Chemie*, 3, 267), and Söderbaum (*ibid.* 6, 45 [1894]).

PLATINUM-AMMONIUM COMPOUNDS (vol. iv. p. 292). Petersen (*Z. P. C.* 10, 580 [1892]) finds, from cryoscopic determinations, that most of the formulæ generally used for these compounds are molecular. For a discussion of the constitutions of several classes of these compounds, and for measurements of the electrical conductivities of aqueous solutions of some of them, *v.* Werner a. Miolati (*Z. P. C.* 12, 35 [1893]).

POTASSIUM (vol. iv. p. 297). Holt a. Sims (*C. J.* 65, 432 [1894]) found that K became soft at 54·5°, and remained soft to 60·5°, whereat it became brittle; complete melting occurred at 62·5°. H. a. S. say that dry K may be distilled in dry O without the formation of any compound of the two elements. They found the products of the oxidation of K to be K_2O_2, K_2O_3, and finally K_2O_4 (*v. Oxides, infra*). Mixtures of KNO_2 and KNO_3 were formed by oxidising K in NO and in the red oxides of N.

Potassium amide (vol. iv. p. 299). Titherley (*C. J.* 65, 504 [1894]) says that KNH_2 is white and wax-like, melting at 270°–272°. It may be distilled without change in H at 400°–500°. T. says that KNH_2 is not decomposed by heating at c. 400° in a silver boat; if a glass vessel is used, NH_3 is given off with some N and H, and K silicate is formed; a small amount of decomposition occurs in a silver boat at c. 500°, and at a full red heat the amide distils with partial splitting up into its elements. For other reactions of KNH_2, *v.* T. (*l.c.*).

Potassammonium (vol. iv. p. 299). Joannis (*C. R.* 118, 713 [1894]) finds that there is no reaction between N and $N_2H_6K_2$; he says that N_2O produces KNH_2, NH_3, KOH, and N. For the action of O, *v.* J. (*C. R.* 116, 1370; *abstract* in *C. J.* 64 [11], 462 [1893]).

Potassium bromide (vol. iv. p. 299). The melting-point is given as 715° by V. Meyer a. Riddle (*B.* 26, 2443 [1893]).

Potassium chloride (vol. iv. p. 300). Melts at 766°, according to M. a. R. (*l.c.*).

Potassium hydroxide (vol. iv. p. 302). Melts at 1045° (M. a. R., *l.c.*).

Potassium iodide (vol. iv. p. 303). Melts at 623° (M. a. R., *l.c.*). Regarding the interaction of KIAq and $FeCl_3Aq$, *v.* FERRIC CHLORIDE, *Addenda*, p. 913.

Potassium tri-iodide (vol. iv. p. 304). Jakovkin (*Z. P. C.* 13, 539 [1894]) has made an examination of the dissociation of KI_3 in aqueous solution to KIAq and IAq (*abstract* in *C. J.* 66 [11], 271 [1894]).

Potassium nitride (vol. iv. p. 304). The experiments of Titherley (*C. J.* 65, 51[illegible] [1894]) show that K_3N does not exist.

Potassium oxides (vol. iv. p. 304). Holt a. Sims (*C. J.* 65, 432 [1894]) failed to obtain the *monoxide* K_2O by any of the methods said to give this compound, but they say that when K_2O_4 is kept at a red heat it loses O and gives a substance the composition of which approaches that of K_2O. By heating K in a fairly dry mixture of O and N, oxidation proceeded until K_2O_4 was formed (*dry* O is without action on K); when kept in water-vapour K_2O_4 gave off O, and formed K_2O_2; and by heating K in N_2O, H. a. S. obtained K_2O_3, which on exposure to air became K_2O_4.

RUBIDIUM.

Rubidium haloid compounds (vol. iv. p. 413). Wheeler (*Am. S.* [3] 46, 88 [1893]) has prepared *double compounds* of the forms $3RbX.AsX_3$ and $RbX.As_2O_3$; and (*l.c.* p. 269) various compounds of RbX with SbX_3. For physical properties of various salts of Rb, *v.* Erdmann, *Ar. Ph.* 232, 3 (*abstract* in *C. J.* 66 [11], 351 [1894]).

SELENATES (vol. iv. p. 43[illegible]). *Basic salts* of Co and Cu are described by Bogdan (*Bl.* [3] 9, 584; *abstract* in *C. J.* 66 [11], 16 [1894]); the compositions given are $4CoO.3SeO_3.aq$ and $3CuO.2SeO_3.4aq$.

SILICON CHLORIDES (vol. iv. p. 458). In *B.* 27, 1943 [1894] Gattermann a. Weinlig detail the best conditions for preparing $SiCl_4$, $SiHCl_3$, and Si_2Cl_6, from crude Si obtained by the interaction of SiO_2 and Mg powder (*v.* vol. iv. p. 455). Si_2Cl_6 melts at $-1°$; with NH_3Aq it gives off H and forms $SiO_2.xH_2O$ (G. a. W., *l.c.*).

Silicon octochloride Si_4Cl_8. Mol. w. 366·9. V.D. 187·7. Obtained by G. a. W. (*l.c.*) by fractionating crude Si chlorides; boils from 210° to 215°; does not solidify at $-12°$.

SILVER (vol. iv. p. 464). The molecule of Ag in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). According to Lüdtke (*W.* 50, 678; *abstract* in *C. J.* 66 [11], 92 [1894]), thin deposits of Ag on glass, mica, &c., are allotropic forms of the metal. Regarding *alloys* of Ag with *cadmium*, *v.* Heycock a. Neville (*C. J.* 65, 65 [1894]); *v.* also Mylius a. Fromm (*B.* 27, 630 [1894]).

Silver chloride (vol. iv. p. 468). By the action of $HgCl_2Aq$ on pulverulent silver, Jones (*S. C. I.* 12, 983; *abstract* in *C. J.* 66 [11], 138 [1894]) obtained the compound $AgHgCl_2$.

SODIUM (vol. iv. p. 473). The molecule of sodium in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). Holt a. Sims (*C. J.* 65, 440 [1894]) found that *dry* sodium may be distilled unchanged in *dry* O; in ordinary O the products are Na_2O and Na_2O_2. Heating to 180°–200° in a limited volume of N_2O forms Na_2O; heating in NO or the red oxides of N produces a mixture of $NaNO_2$ and $NaNO_3$ (H. a. S., *l.c.*).

Sodium amide (vol. iv. p. 475). Titherley (*C. J.* 65, 504 [1894]) describes $NaNH_2$ as a white, transparent solid, with a crystalline structure; softens at 149°, and is completely melted at 155° to a colourless liquid. $NaNH_2$ is obtained in transparent, crystalline needles by heating Na in NH_3 at c. 400°, allowing the product to sublime through a narrow tube, and again subliming by warming gently. $NaNH_2$ decomposes at a red heat into Na, N, and H. It does not give NaN_3, as generally stated (T., *l.c.*); no decomposition occurs at 300°-400°.

Sodium bromide (vol. iv. p. 476). Panfilov (*J. R.* 25, 272 [1893]) obtained NaBr. 5aq by exposing conc. NaBrAq out of doors in winter in Russia; decomposed at −25° to the dihydrate and water.

Sodium iodide (vol. iv. p. 481). NaI. 5aq separates from a solution of 100 g. NaI in 50 c.c. water at −14°; at −10° it gives NaI. 2aq and water (P., *l.c.*).

Sodium nitride (vol. iv. p. 482). NaN_3 is not formed by the interaction of Na or Na_2O and NH_3, or Na and N, according to Titherley (*C. J.* 65, 507; *cf. Sodium amide, supra*).

Sodium monoxide (vol. iv. p. 482). Na_2O is formed by heating Na in a limited volume of O at a temperature below 180°; also by heating Na in a limited volume of N_2O at 180°-200° (Holt a. Sims, *C. J.* 65, 442 [1894]). Heated in excess of O, the peroxide Na_2O_2 is formed. H. a. S. say Na_2O is greyish white. NH_3 reacts with gently heated Na_2O to form $NaNH_2$ and H_2O (Titherley, *C. J.* 65, 510).

Sodium dioxide (vol. iv. p. 483). Na_2O_2 does not combine with O when heated therein (H. a. S., *l.c.*). Regarding the interaction of Na_2O_2 and an alcoholic solution of HCl, *v.* Tafel (*B.* 27, 816 [1894]). For reactions of Na_2O_2, *v.* Poleck, *B.* 27, 2051 (*abstract* in *C. J.* 66 [11], 816).

STRONTIUM. For *Strontium carbide*, *v.* Moissan, *C. R.* 118, 683 (*abstract* in *C. J.* 66 [11], 318 [1894]).

SULPHATES (vol. iv. p. 567).

Chromium sulphates (vol. iv. p. 570). *Double salts* of $Cr_2(SO_4)_3$ and $(NH_4)_2SO_4$ are described by Klobb (*Bl.* [3] 9, 663; *abstract* in *C. J.* 66 [11], 95 [1894]).

Vanadium sulphates (*v.* this vol. pp. 847, 848, 850).

OXY-IMIDO SULPHONATES (vol. iv. p. 602). Divers a. Haga have published a lengthy communication on these salts in *C. J.* 65, 523 [1894].

SULPHUR (vol. iv. p. 606). For measurements of the viscosity of molten S at different temperatures, *v.* Brunhes a. Dussy, *C. R.* 118, 1045 (*abstract* in *C. J.* 66 [11], 343 [1894]).

THALLIUM (vol. iv. p. 674). The molecule of Tl in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]).

Thallium tri-iodide TlI_3. Wells a. Penfield (*Zeit. f. anorg. Chemie*, 6, 312; *abstract* in *C. J.* 66 [11], 318 [1894]) obtained this compound, in rhombic crystals, $a:b:c = \cdot6828:1:1\cdot1217$, by digesting TlI and I with alcohol and evaporating over H_2SO_4.
